PREFACE.

In a year in which the community generally has suffered so much from financial difficulties, and in which the government has been occupied with party discussions and foreign wars, we may esteem it fortunate that both in architecture and engineering no retrogradation has taken place. Although architecture has no great memorials of the present year to show us, yet its labours have been great, while its prospects are most promising, and if neither remarkable for the completion nor the commencement of any gigantic design, it can scarcely be denied that the present is a period of the brightest augury. The necessity for the New Courts of Law may be considered as acknowledged, while the appointment of new judges makes their erection more urgent, the appointment of a commission to consider in what way the Fine Arts can best be made available in the New Houses of Parliament, with the addition of the Victoria Record Tower to the plan of that building, the recognized advantage to be derived from the embankment of the Thames—all these are circumstances which are calculated to inspire the greatest satisfaction.

While prospects of employment are being opened to the profession, its general advancement may be looked upon with equal pleasure; the question of competition is one which has been much agitated during the present year, and good can scarcely fail to arise from the mode in which the extra-professional press have entered into the discussion. The arts have for the first time been made a part of general education by the appointment of Mr. Dyce, at King's College, to a professorship of this branch of instruction, and in the same institution a school of architecture is also formed, so that architecture may henceforth be regarded as adopted into the universitary system. The legislature in the late session took, upon a bold and comprehensive scale, a plan for the application of architectural police and hygiene, and political difficulties alone retarded measures, the principle of which was generally admitted. In the sister country the late representative of the crown followed up the bestowal of royal patronage on the Institute of Irish Architects by conferring on its president Sir Richard Morrison, the honour of knighthood, and in the present Viceroy, the long honoured President of the Institute here, we hope to see a generous encourager of all the liberal arts. The extension of museums, and the re-opening of Westminster Abbey are measures calculated to promote the moral welfare of architecture, while its material interests have not been neglected. A general improvement and extension of the royal parks has been commenced, the Green Park, Hyde Park, Regent's Park, and Windsor Park are undergoing extensive alterations, a new Royal Kitchen Garden is to be formed, the Kitchen Garden in Kensington Gardens removed, the East of London to be improved by the opening of Victoria Park, and other Parks are contemplated in the South. The new streets in the metropolis and the improvements in Trafalgar Square have proceeded but slowly, but the difficulties with regard to them have now been overcome. The new street to the Post Office has however been cleared, and the approaches to the Royal Exchange nearly completed. The strike of a large body of masons caused considerable delay with the Houses of Parliament and the works in Trafalgar Square, otherwise the new buildings have gone on well. The Royal Stables at Windsor and the Wesleyan Centenary Hall, have been completed; St. Bartholomew's Hospital has been extended, the Lock Hospital commenced, and a Gresham Lecture Hall: restorations and decorations are proceeding in the Cathedral of Hereford, Westminster Abbey, the Chapel of St. George Windsor, and King's College Cambridge; and the Round Churches in the Temple and at Cambridge; many new Churches have been erected in various parts of the country. The demolition of the old front of the British Museum has commenced, to make way for a new one, but we have this year lost the Great Armoury in the Tower, Astley's Amphitheatre and Vauxhall. The greatest loss architecture has sustained has been by the death of the illustrious Schinkel.

Directing our attention to engineering we find the converse of what we have observed with regard to architecture, for many noble works have been completed, while the continuance of legislative restrictions threatens to check the progress of every department of civil engineering. It may be said, without any important exceptions, that neither for railways, canals or harbours has any act been passed, and mechanical engineering alone remains unscathed. The government instead of affording relief to engineering, brought forward measures which must still further have depressed it, had they not been defeated in the attempt.

In the Colonies we have to notice the increased employment of engineers, particularly in New Zealand. The Bengal Government have at last published a report on the public works, executed by them, and it appears that the other Indian governments have of late been stimulated to carry on extensive improvements of the canals and roads of India.

With regard to the institutions we feel it our duty to point out as a deed worthy of the profession and of the man, the munificent conduct of President Walker, who presented to the Institute one thousand pounds consols as a prize fund. The Institute has shown a praiseworthy disposition to commemorate the great men of the profession, by calling for a series of memoirs. Dublin has been added to the number of engineering universities, courses have been opened in University College, a school is proposed at Manchester, a junior school has been opened at King's College, and a school for engine drivers at the Polytechnic Institution. The first benevolent institution connected with the profession has been founded for the relief of workmen, by the mechanical and marine engineers.

It is with pleasure we chronicle among the events of the year, the knighthood of Sir Isambard Brunel, and the completion of the great works of himself and his son, the Thames Tunnel and the Great Western Railway. The King of the Belgians has also conferred the order of Leopold upon the younger Stephenson.

PREFACE.

One of the most striking features of this year has been the number and importance of the scientific questions which have been agitated. They relate mostly to the phenomena of steam and the construction of engines, impelled by it. They include the discussion on the electricity of steam, on the percussive action attributed to it, on the comparative merits of Cornish and other engines, and of four and six wheel locomotives, and on the combustion of coal. The plans for the improvement of the river Irwell were also made the subject of a public disputation, in which several engineers of eminence took part.

The deaths among eminent men connected with the profession have not been numerous; they are those of Francis Bramah, the engineer, John Rickman, the author of the Life of Telford, and Sir Francis Chantrey, the eminent sculptor.

This year has witnessed the completion of nearly all the railways, for which acts have passed, and we may date from this period the establishment of a connected railway system. The number of miles executed this year is under two hundred and fifty, but the Great Western, South Western and Gosport, Manchester and Leeds, Brighton, Stockton and Hartlepool, and Blackwall Railways have been opened throughout. Additional and partial openings have taken place of the Bristol and Exeter, Manchester and Sheffield, Cheltenham and Great Western, North Eastern, Maryport and Carlisle, Glasgow and Greenock, and Ulster Railways. The Greenwich line is being widened, and the locomotive system has been extended to the Cromford and High Peak Railway. The sudden and unaccountable occurrence of serious accidents on the lines in the autumn of the last year and of the present, gave rise to violent attacks on the railways from the press, and to the suggestion of stringent measures on the part of the Board of Trade, which was however defeated in the attempt. The inefficiency of the Act of last year has been signally shown by the closing of the Brighton Railway shortly after the government inspector had pronounced it to be not only in an efficient state, but to be the best executed work of any that he had seen. A bill for railways in Ireland was introduced by the government, who were compelled to modify it, and it has since been postponed. Not only our engineers, but our workmen, have been called abroad for the execution of the Paris and Rouen Railway, and the Suspension Bridge over the Danube at Pesth.

Wood pavement has been adopted in the neighbourhood of chuches and courts of law, for the purpose of deadening the sound, and it has been laid down on an extensive scale in several of the principal thoroughfares of the metropolis.

The repairs of the bridges over the Thames have been proceeded with, and an extensive embankment of the river is contemplated; the Hungerford Suspension Bridge is in progress, the Thames Tunnel has been opened throughout, and the lighthouse with Mitchell's screw moorings on the Maplin Sands has been finished. A lighthouse on the same construction has been erected at Fleetwood, and many improvements made in the harbour there. A lighthouse entirely of iron has also been constructed in this country and sent out to Jamaica. The Docks at Southampton notwithstanding many difficulties are nearly ready for opening.

The extended use of iron steamers, with that of auxiliary steam power, and the attention devoted to the forms of propellers are the principal things which strike us with regard to marine engineering, together with the progress of sounder views as to the proportions of power to tonnage, and the bulk of the engine. The loss of the President excited much notice in the early part of the year, but no injurious influence to ocean steam navigation has resulted from that casualty. The West India Mail Steamers have been completed, and steam navigation has been extended to theHavannah, to the Upper Elbe, and in Australia. Ocean steam towing has been tried in the Straits of Gibraltar. The war with China has afforded full opportunity for testing the iron war steamers, and proving their value, and the steam navy has been greatly increased.

Gas has been introduced in Sydney, a prelude to its extension in the Australian Continent.

Mechanical engineering has found much employment; although the depression of trade has prevented the erection of new factories, the demand for the export trade has continued to increase. Turkey and many other countries have availed themselves of the skill of our mechanics.

CIVIL ENGINEER AND ARCHITECT'S

JOURNAL.

ON THE CONSTRUCTION OF THE MOLE DES NOIRES, WHICH SHELTERS THE FRONT HARBOUR AND ENTRANCE OF THE GATES OF ST. MALO.

(WITH AN ENGRAVING, PLATE I.)

(Translated from the French of M. Girard de Caudemberg, Engineer-in-Chief of Roads and Bridges.)

THE Mole des Noires, forming part of the general plan of a floating basin which is to be common to St. Malo and St. Servan, has been in progress for the last two years, and is situated as pointed out in fig. 1, stretching from A to B. When the wind bows from S.W. to N.W., it is very much exposed to the action of the sea, and was consequently during its construction exposed to all the most unfavourable contingencies, by which works in direct contact with the sea are affected. For the purpose of opposing this action, a form has been given to the mole of an arc of a circle of 695 feet (212 met.) radius. The breadth of the top, including the parapet, is 19 feet (5·80 met.), which is strictly necessary for preserving a free passage for warping to the upper part, and for giving to the works the stability and resistance necessary to support the difference of pressure resulting from the maximum of the simultaneous elevation and depression of the waves on the two opposite faces. The dimensions of the mole are given in the section, fig. 2, in which are also shown the high and low water marks at spring and neap tides, which sufficiently justify the great elevation given to the work. This section also shows the great aqueduct or interior tunnel, and of the channels communicating with it. The aqueduct extends the whole length of the mole up to the head, and the upper and lower channels or pipes are made at every 65 feet distance. The lower inclined pipes end in a number of sluices, which are for the purpose of clearing away the silt in the front harbour.

The opinion of M. de Caudemberg was that this silt was little to be feared, but as the commissioners appointed by the Minister of Marine, insisted upon having an aqueduct which could work the sluices, in the front harbour, M. de Caudemberg suggested the plan now in execution. The aqueduct is 1978 feet (603 met.) in length and 7 feet 2 inches (2·20 met.) diameter, and is carried through the mass of the quay of the front harbour, crosses the gates of the inner harbour, and takes its rise in the floating basin. It is constructed throughout of an annular form. The pipes carrying the water to the sluices are inclined as represented in the section, and are of cast iron, their inner diameter is about 16 inches (0·40 met.), and the different parts which compose them are secured by a simple joint with resinous mastic. The upper part is terminated by a hemispherical cup 18 inches diameter, with a ball acting as a bomb valve. This valve is for the purpose of preventing the water introduced into the great aqueduct returning back again when the tide falls. Where however the sluices are intended to be worked the valve is lifted up, by means of a chain communicating with the upper surface of the quay. The water which flows from the aqueduct, through the inclined pipes, with the velocity of a column of water 24 feet high is carried through an opening 3 feet 3 inches broad, and of a mean height of 5 inches, so as to cause a stream of water to sweep away the silt. It should be observed that the large vertical pipes 19 inches (½ met.) diameter, serve for the evacuation of the air, and as manholes for cleansing and repairing the aqueduct. The parts marked *a b c* in fig. 2, are for the purpose of preventing the water at high tides from getting through the sluices, and causing an inverse pressure on the great aqueduct.

The engineer found considerable difficulty while constructing the mole, on account of the position of the great aqueduct, which as it was necessarily built upon a centering, would in case of wood being employed, have been soon blown up by the waves and destroyed, or at least have had the mortar forced out and the work to begin over again. To prevent this M. de Caudemberg directed his attention to the construction of a peculiar centering or shield. This centering was of cast iron, in moveable pieces, so that it should be readily managed in the progress of the works. On the outside was fixed an arm to break the power of the wave at the period of the shock, while at the same time the specific weight of the centering prevented it from being carried away. It is formed of panels weighing about a hundred weight each, so that they could be easily moved. The whole shield was 26 feet (8 met.) long, and divided into 16 rings.

M. De Caudemberg found that though by these means he broke the shock of the wave, that the works were still liable to suffer on account of the oscillations, particularly when the weather was rough, when masses of compressed air were forced into the great aqueduct, and so up the vertical manholes, causing spouts of water 30 or 40 feet high. These manholes however served greatly to modify the effects. As the best remedy, and one which was found effectual, the panels of the centering were covered with sheet iron, pierced with holes so as still further to break the violence of the shock.

As however the cast iron centering was in some degree an impediment to the works, whenever the state of the weather permitted it, a wooden shield was used also moveable, so that keeping 6 feet and a half of iron centering outside, about 50 feet of wood centering was used behind it. In this way 50 or 60 feet in length was got through in a day. To get over the difficulties and expense of transporting the materials to such a narrow space, small lighters, flat bottomed boats, and floating platforms were used, which were found to act well, although some inconvenience was felt in rough weather.

ON THE CONSTRUCTION OF A PIER IN THE RIVER AGLY.

(Translated from the French of M. Fauvelle, for the C. E. & A. Journal.)

M. FAUVELLE describes a process which is extensively used in Roussillon for constructing wells, and has also been applied by Mr. Brunel on a large scale in making the descending shafts of the Thames Tunnel. In most parts of Roussillon, and particularly on the shores of the sea, and near ponds, at a yard or two below the surface, a layer of quicksand is met with, which cannot be dug twenty inches deep without the sand falling and filling up the excavation. This consequently prevents the usual course of digging a well and building the brickwork afterwards, as it would cost more in timbering and framework than the whole well was worth. A stout circular oaken curb is therefore placed on the ground, the walls of the well are built several yards high upon it, and then from the inside the shifting soil is excavating so that the well is carried down to the required depth. M. Fauvelle had to build the pier of a bridge in the bed of the river Agly on a bed, which although it seemed quite dry, yet filtered a great quantity of water through pebbles and sand for yards thick, these again resting on a bed of clay. Being prevented from want of funds from using the ordinary means of getting rid of the water, M. Fauvelle availed himself of the Roussillonese plan. On the bank he placed an oaken frame or curb, and on this he built a well or circular tower of brick, 16 inches thick, 70 feet in circumference, and 13 feet high. This well was secured internally so as to resist the external and vertical pressure. Excavations were then begun in the interior of the well, but some injury was done to the walls at first by the workmen digging under the curb, and so causing an unequal descent and cracking of the bricks. The works were then limited to the interior of the well, and it gradually descended until it became necessary to use the dredge, by means of which, in about a fortnight, it was got down into the clay bed without any accident or injury to the walls. Nothing then remained but to fill up the interior so as to make a solid mass, which was done, without taking out the water, by throwing in concrete and stones, this work being secured to the walls by their being roughed with a chisel worked by a long iron bar: the whole was then well rammed down by two men so as to make a solid mass.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXII.

> "I must have liberty
> Withal, as large a charter as the wind,
> To blow on whom I please."

I. "ARCHITECTURE," says a writer in the last number of the Monthly Review, "is under a certain degree of restraint in every state of society. The nature of his materials, and the necessity of clipping down his conceptions to the views and wants of his employer, have accustomed the architect to act with apparent freedom, under circumstances which would wholly repress the ardour of the sculptor or the painter." This is rather oddly expressed, it being not very much unlike a contradiction in terms to attribute *freedom*, or apparent freedom, on the part of architects, to the *restraint* imposed upon their art. The writer does not seem to have taken the trouble of reading over what he had put down upon paper: but his meaning probably is, that the necessity of clipping down his conceptions, &c., has accustomed the architect to act with a servile compliance—a blind deference, to the wishes of his employers, and to do just as he is dictated to do, as if it were perfect matter of indifference to him: whereas a sculptor or painter is not quite so docile, but less patient of impertinent interference, and is apt to prove restive on such occasions, or else gets sulky, and pretends that he can do nothing if not allowed to have his own way. This, I conceive, would be much nearer the truth: for I do not understand how the architect can be said to act with apparent freedom, when, however willingly he may do so, making a virtue of necessity, he is evidently acting under control, and obliged to forego his own ideas, and maim his design by adopting those of other people.

II. There is, I suspect, no small share of hypocrisy, and not a little cowardice, also, with some addition of affectation into the bargain, in the praises heaped upon Palladio, because I have never yet either met with books, or been able to gather from any one in conversation, in which of his works the merits so liberally ascribed to him really consist. In speaking of him, every one seems to think it the safest policy to confine himself to general eulogy, without venturing at all into particulars. Nay, I have met with those who, after surrendering up to criticism, one by one, every production of his mentioned, have not had *courage* enough to confess that they were advocating a losing cause, but give themselves the airs of having the better of the argument, because, forsooth, Palladio had always been considered a very genius in architecture.

III. It is not without reason that Klenze has lately animadverted upon the plodding, barren, "machine-like," manner in which modern architects have applied themselves to Grecian architecture, without getting a step beyond two or three very obvious and stale ideas, which have now been hackneyed *ad nauseam*; as if its elements could not, by any possibility, be made to furnish fresh combinations or farther modifications as to detail, but every thing must be most according to precedent, at least, as far as columns alone are concerned, since, in regard to all the rest, a most convenient degree of latitude is considered quite allowable. It must not, however, be supposed that such "machine-like" system, one so utterly at variance with every principle of art, would be upheld in the manner it has been and continues to be, without some motive, although it is one which it would not do to let all the world know. The excessive reverence affected to be entertained by the *plodders* for antique examples, evidently does not proceed from an intelligent admiration of them: for it is plainly to be perceived that they have no influence whatever on their taste, and that if such admirers have studied them at all, it has been no otherwise than mechanically, without imbibing any of their spirit, without extracting from them any of their delicious flavour, after the fashion of that most praiseworthy little plagiarist, the bee, who steals their sweetness from flowers, but manufactures it into the still more luscious sweetness of honey. The dunces in the profession —and if any one chooses to include himself among the number, it is no fault of mine—the dunces, I say, are well aware that it is good policy in them to decry any modification of the antique, any thing like originality in the treatment of it, as most dangerous and mischievous innovation. Mischievous, indeed! no doubt—because were any sort of freedom in that respect to be allowed, were the system of copying and nothing but copying, to be exploded, as not exactly in character with what, justly or not, assumes to be something more than a mechanical science, even one of the fine arts,—the incompetence of many would at once become apparent, they being, as Wightwick has wickedly observed, "impotent to generate" even a single modification of what they now so *classically* follow as patterns; much more, then, to generate an idea of their own.

IV. It is by no means uncommon to hear people complain how exceedingly difficult it is to hit upon any new subject; nevertheless, there are both a good many hackneyed ones, which would admit of being treated with some degree of novelty, by blowing away the *learned* dust which now almost covers them, and freshening them up anew; and also a few others that have as yet not been touched upon at all, notwithstanding that they would furnish matter almost inexhaustible, and the opening of them would be like opening a virgin mine of unexplored wealth. It is odd that, until the other day, no one should have thought of treating the subject of porticoes as is done in the article in the Penny Cyclopædia, which, although unsatisfactory, because little more than a brief outline of it, is most valuable as a hint, and as pointing out what preceding writers had overlooked. I, myself, have at least half a dozen architectural subjects *in petto*, any one of which would supply matter for a volume, and some one of which I have long been expecting to see pounced upon and taken up by some less indolent or more enterprizing mortal. Nevertheless, they still all remain untouched, as safe and as snug as if they were buried within the innermost bowels of the earth, though really exposed where any one who has eyes to see with may behold them. There is plenty of fresh game to start, had but people noses to catch scent of it; for instance ————, and ————, and ————, I leave it to the reader's penetration to fill up the blanks,—all choice and fertile subjects as well as new, and only waiting for some one to pick them up; though I fancy that were they to stumble against them, most people would only stumble over them. It is undoubtedly very fine to be eternally talking about "Pericles," and such very *sublime* matters: yet that is not the way to discover any thing particularly novel. Those who walk abroad star-gazing, do not notice a purse of gold under their feet, or should they chance to tread upon it, only kick it away from them as a mere stone in their path.

V. The author of the "Palace of Architecture" has, I see, thought it necessary to assure the readers of Fraser's Magazine, that the article entitled "Wightwickism," in that periodical, was not a slashing cut-up of his book, as some of his own friends had conceived it to be, and were accordingly very indignant that such a violent attack upon it—nothing less than a downright demolisher—should have proceeded from that quarter; nor are they the only persons who have taken up that singular idea, for some sapient newspaper critic has described the paper alluded to as a complete settler for Wightwick! It is charitable, therefore, to suppose that both the reviewer alluded to, and those who have fallen into the same error, read no more than the first page or two of the article, otherwise they must be obtuse and obfuscated indeed, not to perceive its real drift. But there are people in the world so dully matter-of-fact, as to have no notion whatever of either irony or humour—people who take such a pleasantry as "A Lesson in Reviewing" for a serious attack upon Mr. William Cowper, the poet, fancying the writer to be in earnest when he gravely censures the bard's indelicacy, or rather offensive grossness, in venturing to use the term breeches, instead of employing the long-winded circumlocution resorted to by his biographer, Dr. Southey, in order to express, or rather insinuate the idea of, that vulgar article of male attire. And there are folks, it now appears, who either are, or affect to be, so perversely thick-headed as altogether to misconceive the writer's object in "Wightwickism." Nevertheless, with such exquisite stupidity staring us in the face, the present age is styled that of the March of Intellect—which "March," is, perhaps, the gravest and most notable mystification of all.

ON LIMES.

Researches on the several properties which may be communicated to cement stones and hydraulic limes, by imperfect burning. By M. N. Vicat.

(Translated for the C. E. and A. Journal.)

The principal object of this treatise is to illustrate several singular properties of imperfectly burned argilo-calcareous substances, and also some anomalous cases with regard to hydraulic limes. It is well known that hydraulic limes are converted into cements, when the proportion of clay is increased beyond a certain limit, in which transition may be recognised the nature of those compounds which participating in the properties, both of limes and cements, belong to neither class. Those compounds, which the author denominates *chaux limites*, or intermediate limes, on being completely burned, (that is, entirely deprived of carbonic acid), and treated like cements, become absolute cements, but if the cohesion be instantaneously acquired, it is lost in a few hours by a gradual extinction of the cementing properties, which instead of producing hydraulic lime, leave nothing but a kind of caput mortuum. Common hydraulic limestones have also peculiarities, becoming good cements, or giving products almost without value, according as they are burned to a greater or less degree.

The confusion resulting from such apparent inconsistencies, and the serious difficulties which had occurred in carrying on several important works, induced M. Vicat to investigate the subject, and to present the following observations as the result of his inquiries.

1st. All limestones containing 53 per cent. of clay should be rejected as extremely dangerous, and never allowed to be used in any operation, being incapable of forming any useful cement.

2nd. Perfect imitation of hydraulic limes by the mixture of slack lime and cement is impossible: as these mixtures are but slightly hydraulic, therefore to imitate natural hydraulic limes, the regular process must be followed.

3rd. Every argilo-calcareous substance, capable of producing a cement after being thoroughly burned, also gives a cement on being imperfectly burned, provided that the proportion of clay to free lime in the rough stone, does not exceed 273 per cent., or in other words, provided that there are less than 273 parts of clay for every hundred of lime. In acting upon this rule, super calcination is the only thing to be guarded against.

4th. Every argilo-calcareous substance, capable of producing an *intermediate* or hydraulic lime by being thoroughly burned, can on being imperfectly burned, produce a cement, or at least a product having all the properties of one, provided that the proportion of clay to free lime in the rough stone is not below 62 per cent., not only the imperfectly burned stones are no longer cements, but they may even fall into the class of weak hydraulic limes with a gradual extinction of power. As therefore no practical means exists of distinguishing at first sight imperfectly burned cements from those which are burned, and still less of regulating the degree of heat, so as to expel uniformly the required proportion of carbonic acid, it follows that by pulverising imperfectly burned cements, and mixing them indiscriminately with mortar as has been done on several works, the mortar instead of being improved, has had introduced into it an element of destruction.

Lastly. The manufacture of cement from intermediate limes is attended with serious difficulties, as it is impossible to find out which are perfectly burned. Every assay for the purpose of testing the quality of hydraulic lime, should be preceded by experiments on the quantity of carbonic acid contained in the lime, for if this acid is present in such a proportion as to show imperfectly burned non-cement, the assay will point out as bad an hydraulic lime, which thoroughly burned, would have the required qualities.

To the presence of imperfectly burned cements, M. Vicat attributes most of the injuries, splitting of joints, &c., visible in buildings, and which never occur when the lime is good. As the quickest and surest test M. Vicat recommends chemical analysis, but disapproves of the ordinary mode, for if the clay be separated from the carbonate by an acid and then treated with potass, a gelatinous silex is produced from those quartrose particles which do not enter into combination. He therefore recommends the immediate reduction of a few finely powdered grains into lime or cement; to make sure that no carbonic acid remains, and to dissolve the whole in an excess of hydrochlaric acid. The residue, not reduced, will give the quantity of uncombined clay which imbibes the hydraulicity of the lime. The rest of the assay may proceed in the usual way.

OPENING OF THE PORT OF FLEETWOOD-ON-WYRE TO NIGHT NAVIGATION.

This interesting and important event took place on the evening of the 1st of December. It must ever be interesting to behold the efforts of art founded on pure science, when supported by spirited funds, eminently successful. It must ever be appreciated as a vital achievement when a region, hitherto unapproachable by night and seldom by day in stormy weather or slanting winds, shall be pronounced and proved, not only accessible, but within the instant comprehension of the weather-driven mariner, even though he never saw the coast before. Such have resulted at Fleetwood-on-Wyre, under the plans and personal superintendence of Capt. Henry Mangles Denham, R.N., F.R.S., consulting marine surveyor, supported by the encouraging confidence of the board of directors, and unflinching appropriation of means. It is our pleasing task to record facts so honourable and gratulatory to all parties engaged. Here is a Company realising all that is due to energetic espousal of capabilities which might as heretofore, have laid useless to a nation, and unprofitable to enterprise, but for the exercise of perception and that moral courage which boldly traces in perspective reasonable results. An estuary hitherto (indeed 16 months ago) overlapped by spits on its seaward reach, precluding intercourse with its natural tidal basin and anchorage, now presents a straight course, of but 15 minutes run, between 20 fathoms Irish Sea water and the railway terminus, which is connected by 11 hour, journey with London. The full particulars of which are set forth and illustrated in Capt. Denham's work on the Mersey, Dee, and Wyre navigation. We, therefore, need only revert to it, and glance at the simple, but effective ceremony which locally marked the occasion of formally opening the Port. At sunset on the evening of the 1st December, the Chairman, Sir Hesketh Fleetwood, Bart., M.P., a party of 80 gentlemen, their Secretary, John Power, Esq., and last, but not least, some fair ladies, accompanied Captain Denham in a steamer to the offing. Passing the several buoys which mark the New Cut channel, for daylight and hazy weather guidance—at a proper period of darkness, when no vestige or clue to land, or haven entrance, could be traced, and no access to be hoped for until the next morning, a rocket was thrown by Capt. Denham, and instantly the lantern chambers of the new light-houses were unmasked. Three hearty cheers welcomed the lights on board, and three more with every hand open, greeted Captain Denham; whilst peals of cannon on shore called attention to the fact. The lights were then brought in line, the course shaped, and at a nine knot rate the party were, in fifteen minutes alongside the Railway wharf. The instant of clearing the New Cut was signalled by a shower of rockets from on board. Cheer after cheer was responded to on shore by guns, rockets, and cheers; whilst the bands sent forth our glorious national anthem and Rule Britannia. Truth and candour avowed itself where 'tis ever nurtured. One of the ladies exclaimed, to the delight of the gallant Captain,—"Why the process of coming into this port is so simple I could bring a vessel in." —*Railway Magazine.*

WHITELAW AND STIRRAT'S PATENT WATER MILL.

Fig. 1

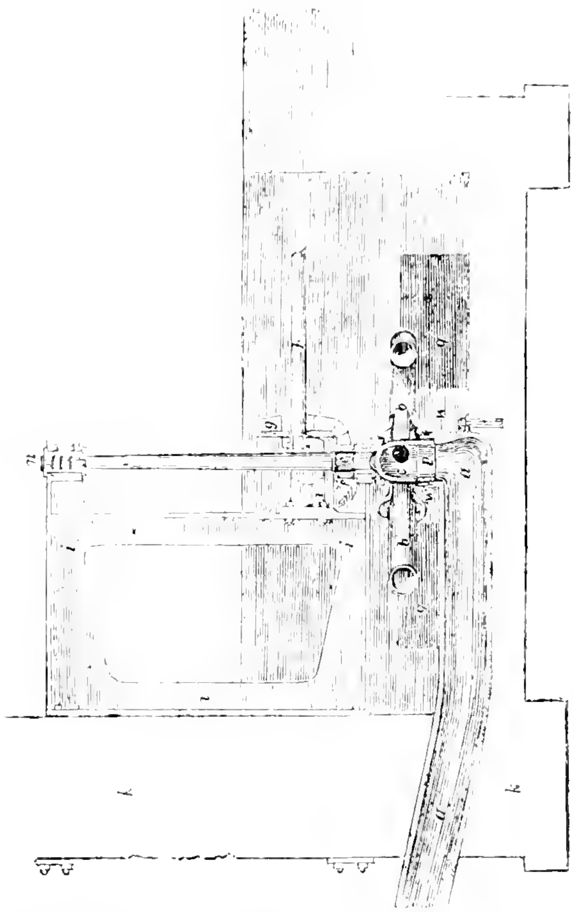

Fig. 1 is a side elevation of the new water-mill, in which figure some of the parts are drawn in section. Fig. 2 is a plan showing the arms and other parts of the machine. The main pipe *a a* carries the water which drives the machine into its arms, from a reservoir or any suitable place on a higher level than the arms: *b b* are the arms, which are hollow: the water passes into them at the centre part *c*, and escapes out at the jet-pipes *d d*: *e e* is the main or driving shaft of the machine, which is shown cast in one piece with the arms: *f* is a bevel pinion, and *g* a bevel wheel; by means of which wheel and pinion the rotary motion of the machine is communicated to the horizontal shaft *h*, which again communicates the power of the machine to any machinery which it may be intended to work: *i i* is a large bracket fixed to the wall or building *k k*; this bracket supports the shaft *e e*, while the bracket *l* carries one end of the shaft *h*. The perpendicular plane which passes through the parts represented in section in the elevation, Fig. 1, passes through the points *m m* in the plan, Fig. 2. The top journal or bearing *n* of the main shaft has a number of collars on it; for, if there were but one collar, it would require to be made larger in diameter than the collars shown in Fig. 1, in order to get a sufficient quantity of bearing surface; but if the diameter of a collar be increased, the friction will be greater, as then the rubbing surface is more distant from the centre of motion; so, if a sufficient quantity of bearing surface is obtained by a number of collars, there will be less friction than if only one is used to resist the pressure. *q q* are holes through which the water escapes from the basin under the arms into the tailrace after it has left the machine. As the arms have a rotary motion, and the pipe *a a* is fixed to the building under it, there must be means provided to prevent the escape of water at the place where the main-pipe meets the arms. A contrivance suitable for this purpose is shown in Fig. 1; it consists of a ring or projection round the underside of the aperture *c*, and of a part *p* turned cylindrical at the place where it fits into the pipe *a a*. A leather, similar to what is used in packing the large piston in a Bramah press, is inserted into the recess *o o*, turned inside of the top part of the pipe *a a*, in order to prevent the escape of water betwixt the pipe and the cylindrical part of *p*. It will now be clear that if the part *p*, and the ring on the underside of *c*, are accurately turned and ground upon each other at the place where they meet, the pressure of the water in the main pipe will act upon the under edge of *p*, and press it in contact with the projecting part round the aperture *c*, and in this way keep the joining of those parts water-tight. There is a flanch outside of *p*, with holes bored in it, to receive steadying-pins fixed to the top part of the pipe *a a*; these pins are seen in Fig. 1; they prevent the part *p* from revolving, and are fitted so as to allow *p* to rise or fall. There is another use for the flanch round *p*, which is this:—a little rope-yarn is wrapped betwixt it and the main pipe, to prevent the part *p* from sliding down whenever there is not a sufficient pressure of water in the main pipe to support it. The pipe *a a* is bored out to receive the part *p*, which is fitted so as that it will slide easily up or down in the bored part; *r r r r* are the stay-bolts which support the arms; *s s* are valves, and *s t s t* are levers which work upon the centres *t t*, and form a connexion of these centres with the valves. There is a lever on the top, and one on the bottom side of each valve. The rods *u u* form a connexion with the levers *s t s t*, and the springs *v v v v*, fixed to the arms. The end next the valve of each jet-pipe (see Fig. 2) is a circle drawn from *t* as a centre: and each valve is curved

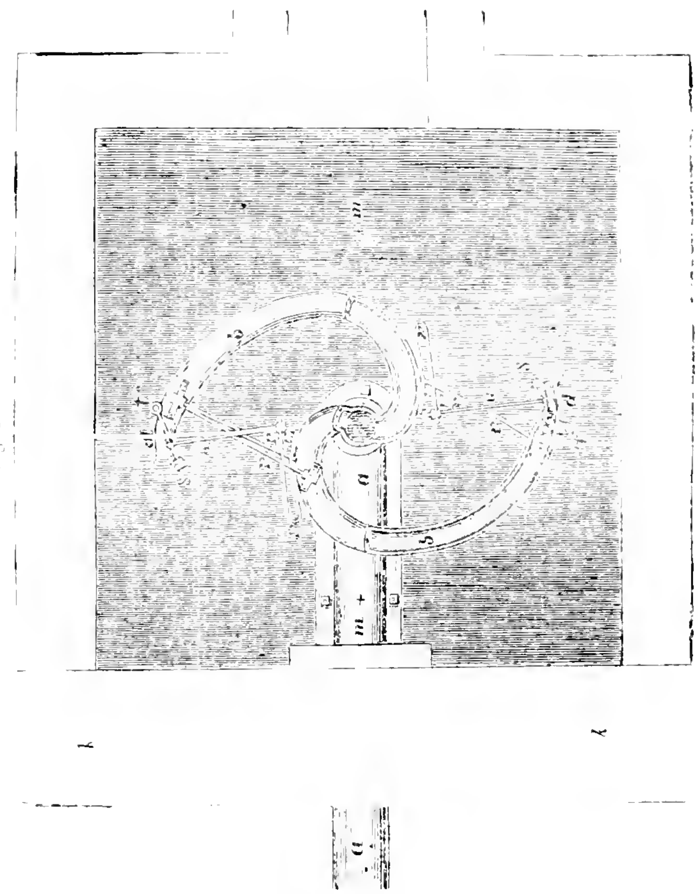
Fig. 2



to fit and work correctly upon the end of its pipe. The levers *s t s t* are adjusted so that the valves *s s* will work without rubbing upon the ends of the jet-pipes, in order to get quit of the friction as much as possible; but it is not essential that the valves should be correctly water-tight. It will be clear, that if the machine revolves so fast as to make the united centrifugal forces of the valves *s s*, the rods *u u*, the levers *s t s t*, and the springs, greater than the weight that will bend the springs *v v v v* to the distance shown in Fig. 2, the valves will recede from the centre of the machine till the force of the springs gets sufficient to overcome the centrifugal force of the valves, &c. Therefore, the centrifugal force will cause the valves to cover the ends of the jet-pipes, and so allow less water to escape, and thus diminish the force of the water on the machine whenever it goes quicker than the proper speed. If the springs are considerably bent

* We are indebted for this description to a pamphlet by James Whitelaw, and for the use of the wood engravings to the Editor of the Mechanics' Magazine.

or strained when the valves are full open, a very small increase of the speed of the machine will cause the valves completely to cover the ends of the jet-pipes, and when the ends of these pipes are closed, the water can have no power to turn the machine. From this it will be clear, that the machine can be made so that, when it is doing very little work, it will not move at a much greater speed than it will when acting with its greatest power.

The new water-mill acts on a principle similar to that of the well-known Barker's mill; but the arms are bent and otherwise shaped, so as to allow the water to run from the centre to the extremity of the arms when they are in motion, in a straight line, or nearly so, and in this way the disadvantages of carrying the water round with the arms, as is the case in Barker's mill, are got rid of.

The curve of the arms is such as to allow the water to run from their centres out of the jet-pipes, without being carried round by the machine, when it is in motion at its best speed. On this account, the rotary motion of the arms will not give to the water a centrifugal force. So the forces which work the new water-mill are simply the force of reaction, and the weight of a column of water of the same height as that acting on the mill, having the area of its cross section equal to the sum of the cross-sectional area of each jet-pipe. When the machine is standing, the one of these forces is as great as the other; but when it revolves so quick that the centres of the jet-pipes move at the same speed as that of the water flowing from them, the force of reaction ceases, as then the water falls from the jet-pipes without any motion, in a horizontal direction, for the machine leaves the water as fast as the acting column can follow it. When the resistance to be overcome is as great as will balance the force caused by the weight of the water, there is still the force of reaction left to bring up the speed of the machine; and as the weight of the water remains the same, whether the machine is in motion or at rest, the force of reaction will carry up the speed till the centres of the jet-pipes revolve at a velocity the same as that of the water issuing from them before it ceases. Thus the machine, when its jet-pipes revolve at a speed as great as that of the water issuing from them, will give its maximum of effect, which maximum will be equal to the whole power of the water it uses; for, in the time a given weight of water is expended, in the same time the machine is able to raise as great a weight from the level of the centres of the jet-pipes to the level of the surface of the water in the lead. There is of course a small part of the power lost, most of which is that caused by the resistance which the water meets with in passing through the main pipe and the machine. This portion of the force is very inconsiderable, as will be shown in the next paragraph; and, by making a slight alteration on some parts of the machine, this small fraction of loss may be still further diminished.

A machine erected lately for Messrs. Neill, Fleming, and Reid, at their works, Shaws-water, Greenock, gives, when tested by the friction apparatus invented by M. Prony, 75 per cent. of the whole power of the water which works it. The power of the water is 79 horses, and the power of the machine is equal to that of 59·25 horses or 75 per cent. as now stated. Mr. Stirrat's water-mill of 2½ horses' power is the first that was made; it was tested in the same way as the above-mentioned machine, and the result of the experiment was equally favourable.

The following are some of the advantages which the hydraulic machine of Messrs. Whitelaw and Stirrat, has over an overshot water-wheel of the best construction. The new mill has a governing apparatus, which renders its motion as uniform as that of the best constructed steam-engine; when a part, or even the whole, of the machinery which it works, is thrown off at once, the variation in the speed is scarcely perceptible. The speed of the new machine is well suited for every purpose: generally speaking, it can be formed to make the required number of turns in a given time, and on this account, intermediate gearing is done away with. There is little wear and tear on the parts of the new mill, for its weight is perfectly balanced by that of the water, thus taking away almost all friction, and consequently wear, at the rubbing parts: five of these machines are already in operation, and not a workman has been employed in any way at either of them since they were first set a-going, although one has been in constant use for nearly two years. The new machine takes up remarkably little room. No very expensive building or other erection is needed for the fixing of the new water-mill, and the cost of the machine itself is very trifling in every case, and especially on a high fall, where an overshot wheel, as also the building and excavation required for it, become enormously expensive. On a fall of very great height, where to erect an ordinary water-wheel would be altogether out of the question, the new water-wheel may be employed to great advantage. The new machine may easily be made to rise or fall according as the water in the tail-race is high or low, and one form of it will work to very considerable advantage in tail-water. The best constructed overshot water-wheel will not, after the speed is brought up for ordinary purposes, give more than 70 per cent. of the whole power of the water which works it; and the new machine, as has already been shown, gives 75 per cent., and it can be formed to give even a greater portion of the power of the water than this.

SUPPLY OF WATER TO THE METROPOLIS.

It is always with much pleasure that we approach this question, interesting as it is not only to the profession, but also to the public at large, being one of those subjects on which both parties meet as on common ground. The supply of water to the population has always with the supply of food generally acquired great political importance, and the provision for it has called forth some of the greatest triumphs of engineering. It has been but too truly stated by Dr. Southwood Smith, in his able Reports on the Health of the Metropolis, that an insufficient or impure supply of water is one of the main causes of disease in all classes of the community, and the means of removing which are well known to be in existence.

The valuable report which we now lay before our readers, proves most clearly to every unbiassed mind that London may be supplied with pure water without having recourse either to the Thames, or to any other river. All rivers and open canals are infected in some degree with vegetable and animal matter, particularly after heavy rains—for instance, even the New River is the receptacle of the land drainage for many miles. The water-works which derive their supply from the Thames are all within the range of the tide, impregnated as it is with the drainage of the metropolis, and the large manufactories on its banks, and so must it always be. The works which stand the farthest up the river, those of the Grand Junction Company at the London end of Brentford, are within the immediate vicinity of large gas works, a soap manufactory, and the drainage of a brewery, and of one of the largest distilleries, without reckoning the drainage of the whole town.

To the Provisional Committee of the London and Westminster Water-Works, &c. &c.

Gentlemen—The insufficiency and badness of the present supply of water to the metropolis have long engaged the public attention; but although many endeavours have been made to establish it on a better basis, owing to causes which we must seek in the elements of the projects themselves, they have invariably failed.

As it appears, however, generally admitted, that something should be done, we are naturally led to inquire into the reasons of the want of success of former attempts, and by carefully avoiding these, and at the same time endeavouring to present an effective and practical remedy, we may still hope to deserve the public confidence. It will, therefore, be my endeavour to show, in the following report, that Nature has supplied us with the means of substituting a pure and unceasing flow of spring water for the outpourings of filthy drains, and that this can be done without encountering difficulties of any but an ordinary nature.

Nevertheless, before I proceed to do this, it may not be useless that I should briefly enumerate the various plans which have hitherto been suggested to attain this object; as this will at once prove how much time and attention, not only numerous private individuals, but even the legislature, have bestowed on the subject; and will also enable me to point out to you what appear to me to have been the causes of their rejection.

So far back as the year 1821, a committee of the House of Commons made a long report, in which they recommended that a bill should be passed to regulate the water companies, which had at that time caused much dissatisfaction, on account of the great increase, which a coalition enabled them to make, on their former rates. The inquiry, although it does not appear to have led to any positive result, nevertheless, called the attention of the public to various facts which were not previously generally known, and among others, to the very inferior quality of water which many of the companies supplied. We accordingly find, that in 1824, a highly respectable body of gentlemen held a meeting, to take into consideration a proposition of Mr. Philip Taylor's, to conduct the water of the Thames, by means of a subterraneous aqueduct, from a point near Richmond, to reservoirs at Kensal Green and Hampstead Heath.

In 1825, a company was formed to supply the metropolis with spring water, from beneath the London clay, a project which was again brought forward in 1835, and to which I shall have occasion, in a later period of this Report, to allude at some length.

But it was not until the spring of 1827 that in consequence of the publication of a pamphlet, entitled "The Dolphin," by Mr. Wright, the general mass of the inhabitants of London could be said to have been aroused to a sense of the paramount importance of a better supply of water to their houses, than that derived from some of the most foul portions of the river Thames. At [illegible] for so great a length of time, in public indignation [illegible] many instances of a meeting held in April 1827, which was attended by a most influential body of the nobility and residents of the West of London, resolutions of a very strong nature were passed, and a petition agreed to, praying for the appointment, by the Crown, of a commission to inquire into the present modes of supply, and their effect on the health of the population.

In compliance with this urgent demand, Dr. Roget, Mr. Brande, and Mr. Telford were named on the 12th July, 1827, to examine the allegations brought forward, which at once led to the suggestion of numerous remedies for an evil, which no one appeared ready to controvert.

Among these we find a Mr. Hipkins proposing to convey in an open conduit the water of the Thames from above Old Brentford; Dr. Harrison, from Isleworth, and Mr. James Mills, from Teddington; Mr. Martin, the artist, also sought to shew that the water of the river Colne might be brought in a canal from Denham, in the neighbourhood of Uxbridge, to London; and in addition to these various other proposals emanated from Messrs. Smart, Brown of Wakefield, Chambers, Jones, William Anderson, &c. &c.

None of these, however, were fully discussed by the commission, as the demand for their Report rendered it necessary that it should be given in long before they could well said to have terminated their labours.

The evidence they obtained enabled them, however, to decide "that the present state of the supply of water requires improvement, that the complaints respecting the quality are well founded, and that the water ought to be derived from other sources than those now resorted to."

In consequence of this report it was deemed necessary that a Select Committee of the House of Commons should be appointed to make further enquiries, and at the end of the session it appears to have fully agreed that the supply should be derived from a purer source than the present, in furtherance of which object it was recommended that Mr. Telford should be employed to make such surveys as would enable him to suggest a practicable plan of supplying every part of London with wholesome and pure water. After several years of protracted enquiry, Mr. Telford came to the conclusion that it would be desirable to bring the water from the river Verulam, on the north side of the Thames, and one of the branches of the Wandle, on the south, to London, to effect which so large an outlay was necessary, that he proposed it should be met by a parliamentary grant.

Another and numerous committee of the House of Commons again met to consider these plans, but its labours were unfortunately not terminated at the end of the session: the enquiry may therefore still be considered as remaining nearly in the same state in which it was left in the year 1834.

The plan of sinking Artesian wells to the sands of the plastic clay or chalk, has indeed, as I have already mentioned, been again mooted, but abandoned for causes to be hereafter detailed; and Mr. Telford's proposal of bringing the water of the Verulam to London has also been taken up, with various modifications, by Mr. Giles, who, however, did not succeed, I believe, in the preliminary step of finding capitalists willing to embark in the undertaking.

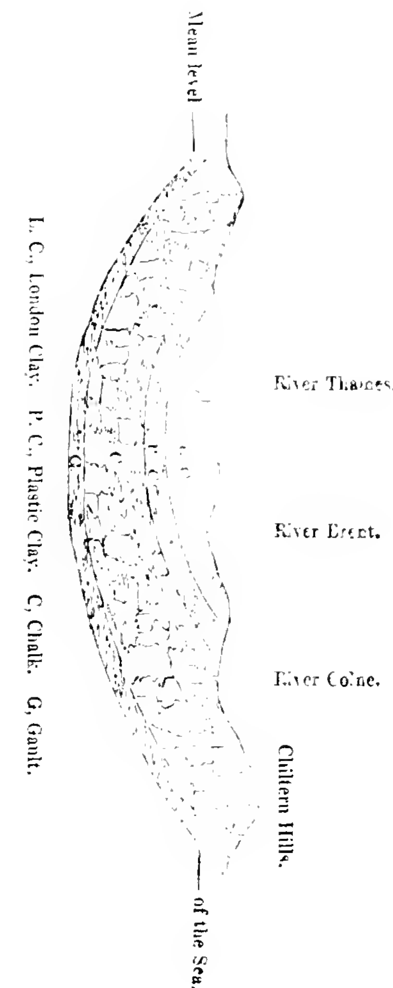
It will now, I think, be sufficiently established that the present mode of supplying London with water, has for a length of time, been any thing but satisfactory to the public; and if for some years past the subject has been allowed to rest, it has probably arisen more from a prevalent idea that the enquiry was in the hands of the legislature than from any real abatement of the grounds of complaint.

From various causes it would seem, however, that there is no intention on the part of tha government to prosecute the enquiry; and, indeed, this may in some degree be accounted for from the country being called upon, according to Mr. Telford's plan, to expend nearly £1,200,000 to carry that into effect which many have already doubtless perceived to be but a partial remedy for the evil.

It is indeed surprising, that with the exception of the proposal to obtain the water by perforating the London clay, every project, including Mr. Telford's, should have contemplated using the water of streams which are all subject to be affected by the surface drainage of a more or less extensive tract of country, and, consequently, only a very few degrees better than that already in use, whilst at the same time all the difficulties consequent on the injury to existing interests, as navigations, mills, &c. have to be encountered. Many, although they sought to remove the objection to using the water of the Thames in the immediate vicinity of London, continued to endeavour to derive their supply from a greater distance, where, although, certainly less liable to contamination, it might still be considered as the common sewer of many important towns on its banks, and the general drain into which much animal and vegetable matter must find its way, particularly after the scouring of the neighbouring country by every heavy fall of rain.

I do not, indeed, at all contest that the extraneous bodies, which pollute the water of rivers, are merely held in mechanical suspension, and that provided we get rid of these by allowing them to fall to the bottom, the Thames water may be looked upon as quite as pure as any other. But there appears to me one material objection to the method of removing the impurities by rest, which applies to all surface water, namely, that a considerable space of time is necessary to admit of their complete separation, and as this is also increased by the slightest agitation again diffusing the particles of the deposit through the water, the gradual accumulation of filth in the reservoirs, and the lapse of time requisite to render the water clear, must undoubtedly add to its unpleasant odour and flavour, or, in other words, to its tendency to become putrid. I therefore repeat, that it is scarcely to be wondered at, that the legislature should have delayed acting on Mr. Telford's plan, which combined these objections with a very large outlay, nor that a company should still have found grounds for proposing Artesian wells in preference to his suggestions. That this, however, was not to have been easily attained, appears partly proved by the fact, that this project was never brought to maturity, and the remarks I am now about to lay before you will also, I trust, confirm this view.

The group of strata, designated as the lower tertiary, or eocene, and consisting of two divisions, the upper called the London clay, and the lower composed of various coloured sands and argillaceous deposits, distinguished as the plastic clay, lying immediately upon the chalk formation, may in general terms be considered as a huge mass of clay resting upon a still more extensive



bed of chalk. The section which accompanies this report, and which, with slight modifications, is taken from Dr. Buckland's Bridgewater Treatise, will shew this clearly, and by inspecting it you will at once understand that the surface of country occupied by the clay, is surrounded on all sides by a belt of chalk, excepting to the east, where the German Ocean for some distance interrupts the continuity, and you will also perceive that this cretaceous circle is, generally speaking, higher in level than the deposit of clay which fills the centre of the basin.

It is almost needless that I should inform you, that of the water which descends as dew or rain upon the surface of the London clay, little, if any, can be considered as absorbed into the earth, and that whilst a part either again reascends into the atmosphere as vapour, or enters into the composition of animal and vegetable bodies, by far the greater portion flows off into the main drain of the district, the river Thames.

In this respect there is a most material difference from that portion of the surface where the chalk comes to light, divested of any covering which could intercept the passage of the moisture; being not only extremely porous but also full of fissures in every direction, a very rapid absorption takes place, and we accordingly find that there are but few streams carrying off the surplus surface water, and that these are insignificant, and, indeed, many of them dry during the greater part of the year. The rapidity with which the water finds its way into the bowels of the earth, also in a great measure, prevents evaporation, and we are therefore justified in assuming that the quantity which descends upon the surface of the chalk finds its way, with very slight diminution, into the fissures below. The lower beds of the cretaceous group, and the gault which immediately succeeds it, again present an impermeable stratum of clay, causing the water to accumulate through the lower regions of the more porous chalk. An enormous natural reservoir has thus been formed and the level up to which it may be considered as quite full of water is the lowest point where it can find a vent and overflow, therefore, as the chalk communicates under the coasts of Norfolk, Suffolk, and Essex with the ocean, this level, in the present case, may be considered to be the same as the mean height of the sea.

That there is, however, an extensive accumulation of water above this level will be obvious, when it is considered that the friction, which from the nature of the small fissures and pores must exist, will necessarily prevent the water from exerting rapidly its hydrostatic pressure, and as for this reason it cannot flow off with sufficient velocity, the higher parts of the chalk belt which surround the London clay being saturated, will allow of its escape to the surface wherever it can find a nearer and more ready vent than its subterranean one.

The greater or lesser facility, which from lines of fissures soft strata and pores, the water may encounter in flowing towards the centre of the basin, will also govern its surface, and cause it to assume an inclination, the angle of which will represent the friction, and in this manner we may readily account for the different levels, which often appear anomalous, at which the water will be found to stand in wells.

The foregoing remarks will now enable me, I think, to show that the proposal of perforating the tertiary clays for the purpose of obtaining the water for the general supply of the inhabitants of London, would not have been attended with the advantages which at first sight it would appear possessed of: it may indeed be urged that a reference to the section, shews us London situated nearly over the centre of the basin to which it gives its name, and that we may consequently infer, that wells sunk through eocene strata into the chalk, will derive their supply immediately from that portion where the greatest accumulation of water exists by my own shewing. But it will be found that this very circumstance throws a material difficulty in the way of any attempt to supply the inhabitants of the Metropolis from this source, and one which has been found frequently confirmed, when private individuals have sunk deep wells in London. The objection is, that whenever a large quantity is extracted, the wells in the vicinity, which derive their water from the same strata, are very sensibly affected: and, for this reason, that although a constant supply will always, as I have shown, find its way down, to take the place of whatever water we may pump away, this cannot flow in so quickly from the obstructions of the stratification, but that the level, for some distance round this focus, will be temporarily reduced. In other parts of the district, as will be readily understood, this would not be the case; or if so at least in an inferior degree, as a well would not here derive its share from every side of the basin at once, but only from that portion situated immediately above it. At Watford, for instance, a well would only be fed from the chalk which intervenes between that place and the great outcropping Chiltern ridge, and so in any other part of the belt. I may also here add, that the sheet of water in the deeper part of the chalk, can only be affected to an insensible degree by such a well, which at most would merely deprive it of the supply from a very trifling part of the great circle which every where else would remain untouched.

The company which had been based on the Artesian project, probably soon obtained facts which proved that their proposal could not be established without such interference with private interests, as they undoubtedly foresaw, would have great weight with the House of Commons; and they must also have taken into account the expense of forcing the requisite quantity of water to the elevation necessary for the high services, in addition to which, it must be borne in mind, that after perforating say two hundred feet of clay, the water under London by no means rises to the surface. As might have been readily foreseen, this idea was after some time, abandoned; and it is not surprising, that its originator, Mr. R. Paten, should have turned his attention to other endeavours.

The abundance of the springs which overflow into the Colne valley, above Watford, and the apparent purity of the water, had long attracted his attention, and now led him, in connexion with some other gentlemen, to make various experiments to ascertain whether a sufficient quantity for the demands of the Metropolis, could be obtained in that neighbourhood, at a small depth beneath the surface; and whether this might be effected without injuring the existing interests in the vicinity. When it was found that the result more than confirmed their most sanguine wishes, I was requested to examine whether the experiments were well grounded, and to advise as to the means of carrying the plan into effect.

I had for a length of time been acquainted with the various proposals which have been submitted to the public, and was aware of the objections which could with justice be urged against them. It was therefore not without pleasure that I undertook the examination of a plan, which I at once saw might be possessed of advantages, which were not before contemplated.

It will be my endeavour, in the remainder of this Report, to show how far the hope of obtaining the necessary quantity of water at Watford is well founded; to describe the experiments which have been made for the purpose of acquiring practical data, to explain the proposed method of procuring the water and conveying it to London; and lastly, to submit such remarks as will enable you, in my opinion, to present the project before parliament with a confident reliance that it cannot but deserve its attention and support.

As I have already described at some length the geological features of the country surrounding London, I am not called upon to add much to my former explanation on this head, and shall confine myself here to stating, that as regards the more immediate object now in view, we may look upon the Colne valley as marking in a great part of its length, on the one side the escarpment caused by the outcrop of the plastic clay, whilst on the other, the country rises gradually to the north-western boundary of the chalk strata, the Chiltern Ridge.

An attempt to fix positive quantities, by any line of argument, is naturally attended with considerable difficulty; nevertheless, the following considerations will give some idea of the volume of water that can be derived from the chalk of the Colne valley.

The surface of country which has its drainage into the Verulam and Colne above Watford may be taken at $113\frac{1}{2}$ square miles. If, then, we assume that the annual fall of rain amounts to twenty inches, which you will find a low average, the result will be $14\frac{1}{2}$ millions of cubic feet of water per twenty-four hours, falling on the surface. Of this quantity, Mr. Telford found that the Colne carried off at Watford, thirty cubic feet per second, or about $2\frac{1}{2}$ millions per twenty-four hours: as this was however in a dry season, it will be safer to assume Dr. Thompson's calculations, with respect to the annual quantity of water flowing off by streams and springs, which he was led to fix at four inches, and this would give us for the area drained by the Colne, not quite three millions per day.

There remain then $11\frac{1}{2}$ millions of cubic feet per twenty-four hours, either to be again evaporated, or to find their way into the earth. In an earlier part of this Report, you will remember that I showed that the porous nature of the soil, in a chalk district, prevents the evaporation to a great extent; nevertheless, if we assume that with the portion which enters into animal and vegetable life, one-third of the entire quantity falling, disappears in this manner, we still shall have upwards of $6\frac{1}{2}$ millions of cubic feet, or 42 millions of gallons per twenty-four hours, supplying the sheet of water under that portion of the chalk surface.

Mr. Telford's examination of the body of water flowing off by the Colne river, having been made at a period of unusual drought, when the surface water might be considered to have nearly disappeared, we shall, I think, be correct in assuming that two millions at least of the quantity he measured, had issued from springs. In order therefore to represent the total subterranean flow, we should add these two millions to the former $6\frac{1}{2}$. These indeed would form no part of the supply to the deep, but would designate that supply which has been already explained, cannot find its way to the lower depths, owing to friction, and other impediments, and therefore seeks a readier vent at a higher level.

It was important that this should be set in its proper light, as the evident inference we may draw is, that we cannot, by pumping from a lower level, a quantity small in comparison to the accumulation of water, produce any visible effect upon the springs which feed the Colne.

I am quite confident that my views as regards the manner in which the water finds its way into the strata of the chalk, will not for a moment be called in doubt by any scientific person, but that which may by such a one be considered in the light of a received axiom, and proved by numerous corresponding facts bearing thereon, with which he will be already acquainted, will require more lengthened demonstration to the general public, with whom an appeal to experience will have far greater weight than any abstract reasoning. To these then the experiments which have been made, will afford far more conviction than any argument however well founded.

The alluvial bed, which covers the bottom of the Colne valley, rather exceeds twenty feet in thickness, after which we reach the chalk; proceeding about five feet lower, abundant springs of water are encountered, which increase in magnitude and force as we continue to descend.

It was therefore in the first place necessary to ascertain that these did not derive their supply directly from the river, which, had it been the case, would have affected the various mills in the vicinity; and it was also desirable to have direct proof of the quantity which might be calculated on being obtained. In order to obtain positive evidence on both these points, a well was sunk in Bushey Hall meadows, near the Colne, to a depth of about 34 feet. Two small steam engines were then set up temporarily, for the purpose of working four pumps, of which two were 13 inches in diameter, with a length of stroke of 20 inches, and the others were $13\frac{1}{2}$ inches in diameter, with a 36 inch stroke. One of the engines might be calculated to produce from 27 to 30 strokes of the smaller pumps per minute, the other between 17 and 20 strokes of the larger pumps. The water of the well was now repeatedly pumped out, as low as the power of the engines admitted, and the height of the Colne at those times carefully noted, and it soon became obvious that the height of the springs could in no degree be said to affect the level of the river, thus shewing that all direct communication between the two might be considered as cut off by a bed of puddle or clay. The next object of enquiry was as to the supply which a well might be expected to yield, and the result of a careful experiment, made under my direction, and confirming those previously conducted by Mr. Paten, satisfied me that after the water had for 24 hours been kept at the lowest level to which the power of the pumps would reduce it, (about 26 feet below its surface when undisturbed,) it rose in the well with a velocity equal to 2·02 feet per second, thus yielding 174,590 cubic feet, or 1,091,000 gallons per 24 hours. As this was obtained in a

... the bottom of which was only 12 feet 6 inches diameter, and as direct proof had been obtained by borings, that below the 34 feet reached in the well there was a constant recurrence of large springs, giving evidence that the water rapidly increased with the depth, which when 80 feet were obtained, became so prodigiously plentiful as to set all temporary means of overcoming it at defiance, and precluded all possibility of having recourse to it for the mere purposes of an experiment, I thought it quite unnecessary to seek further proof that a sufficient supply for all requisite purposes might with facility be obtained.

It would be premature to give, in the present stage of the proceedings, a detailed account of the arrangements I propose making, for augmenting the quantity to an adequate extent, and it may be sufficient to state here *that I have not the slightest doubt*, that by sinking a deep well, and extending tunnels, or drifts in the proper direction from its bottom, *the necessary supply will be fully accomplished.*

Being also convinced that the water filtering through the chalk might be considered as entirely divested of all impurities, held in mechanical suspension, of which, indeed, there was abundant ocular demonstration, (as it was so beautifully transparent as to admit of the bottom of the well being seen when the water was upwards of thirty feet deep,) I at once turned my attention to the best means of conveying it to London.

The principal difficulty which intervenes is the ridge formed by the escarpment at the outcrop of the plastic and London clays, which Mr. Telford in his proposal to bring the water of the Verulam stream to London, had contemplated perforating by a tunnel three and a-half miles in length. My connexion with the London and Birmingham Railway has placed me in possession of facts which convince me that at the level at which Mr. Telford would have traversed some of the beds of the chalk, and the whole of the plastic clay, he would have met with very great difficulty, in consequence of water. For this reason, I propose, on leaving the Colne valley, that before entering the ridge which separates it from the district draining into the Brent, the water should be forced to a height of fifty feet above its original level, at which elevation we get rid of the difficulties of the plastic clay, as we only traverse quite its upper extremity, where no water has yet accumulated. The length of the tunnel is also considerably reduced.

I have preferred adopting a Line which is materially shorter than Mr. Telford's, as, with the exception of the said tunnel 2½ miles in length, no difficulty of any kind is encountered. Immediately on the water re-issuing into the open air on the side of Brockley Hill, I propose forming a reservoir to contain three days' supply of water, with a sufficient head to admit of a main being laid hence, and conveyed, (in order to avoid all opposition from landowners,) from the town of Edgware to Oxford Street, along the side of the road itself; thereby also facilitating the laying of the main, and rendering all the works of any magnitude, as earthwork, aqueducts, &c. unnecessary. The level of the reservoir will lastly be such, that the highest service can be given; and indeed a part of the town, which none of the present companies can supply, will be included within its range.

I trust I have now said enough to convince an unbiassed person that there exists no difficulty, both in obtaining a supply of good water from the Springs of the Chalk, near Watford, and in conveying it thence to London. I must, however, impress you here with the necessity of enforcing my arguments, with as numerous a body of facts as can be collected: and I would therefore recommend that, previously to the meeting of Parliament, I should be authorised to collect such information respecting the quantity, nature and quality of the wells in every part of the chalk circle which surrounds London, as will bear practically on the subject. This might then be embodied in a second part or appendix to this Report, to be submitted to those who, being unacquainted with geological phenomena, may consequently hesitate in adopting views which others, already scientifically acquainted with the subject, will not for a moment call in doubt.

In concluding, I may be allowed to cast a retrospective glance at the advantages held out by the project I have been called upon to examine. These then consist in its being proposed to use spring water, already naturally filtered, in preference to that which has drained a portion of the earth's surface; in making use of that enormous reservoir which nature has supplied us with in the Chalk, and effecting this at a spot where no existing interests can be injured: and in the selection of such a situation as enables us to convey the supply to London with facility and economy, and at a sufficient elevation to satisfy the demands of even the highest part of the metropolis.

I have the honour to be, Gentlemen,
Your obedient servant,
Robert Stephenson.

London, Dec. 16, 1840.

ASSISTANT ENGINES UP INCLINED PLANES.

[At the last Meeting of the London and Croydon Railway, the following reports were read, respecting the use of assistant engines up inclined planes.]

To the Directors of the London and Croydon Railway.

Gentlemen.—According to your instructions, I have written to the Liverpool and Manchester, the Grand Junction, and the London and Birmingham Railways, to ascertain whether the practice of assisting trains up inclined planes by an engine at the rear exists on those lines, and whether it has ever been found to be attended with danger or inconvenience.—I learn that on the Liverpool and Manchester Railway the system is in *daily use*, and that it has never been found to be attended with dangerous consequences: on the contrary, it is considered *safer* with a long train to assist up an inclined plane by an engine behind the train rather than in front.—On the Grand Junction Railway, the assistant engine is behind in assisting up short and steep inclines; but elsewhere the assistant engine, if required for heavy or late trains, takes the lead. Hitherto, neither inconvenience nor danger has resulted from the practice, which is prohibited *except* on inclined planes.—On the London and Birmingham Railway, pushing a train on the line is only allowed in cases where the power cannot be applied in any other way. Your obedient servant,

Charles H. Gregory, Resident Engineer.

December 8th, 1840.

To the Directors of the London and Croydon Railway.

Gentlemen.—According to your instructions, I have this day tried an experiment, in the presence of the Chairman, Deputy-Chairman, and Mr. Baines, for the purpose of determining practically the effect of the assistant engine on the inclined plane at New Cross, and the actual amount of danger to be anticipated from the sustained pressure of the assistant engine in the case of any sudden stoppage of the train before it. With this view, a train was made up of five loaded coal-wagons of a gross weight of 30¾ tons (which is about equal to an ordinary passenger train). The *Croydon* engine was placed at the head of this train, and drew it up the inclined plane, with the *Hercules* engine assisting at the rear.—On the train acquiring a velocity of 22½ miles per hour, the steam of the leading engine was suddenly shut off. The effect was instantaneously felt in the assistant engine, on which the whole weight of the train seemed thrown back, causing a strong re-action, which reduced the velocity of the train to 15 miles per hour, the steam being still acting with full force in the assistant engine. The order was then given to stop the assistant engine: the steam was shut off, and the brake screwed down, when the engine instantly separated from the train, and stopped in less than its own length.—The same train was then taken up by the leading engine alone, and on attaining the same speed of 22½ miles per hour, the steam was shut off. The velocity of the train was reduced for the first furlong from 22½ to 12 or 15 miles per hour, being nearly the same as in the previous case, when the assistant engine was acting behind. The engine and train stopped in a distance of 7-32nds of a mile, without the use of the brake.—The practical inference from this experiment is valuable, as showing that there is a great deal of unnecessary alarm existing as to the supposed danger of the assistant engine on the inclined plane.—First. Any stoppage of the train is instantly felt on the assistant engine, which may be stopped before any serious result can arise from its overrunning the train.—Secondly. The effect of any sudden stoppage of the train is to cause such a sudden re-action on the assistant engine that for the first furlong afterwards it appears to communicate scarcely any impulse to the train, the velocity of the train after the steam is shut off in the leading engine being nearly the same, with or without the action of the assistant engine.—Thirdly. The retarding effect of the inclined plane is so great that the least obstruction would be sufficient to stop the train in a very short distance, even when the assistant engine is acting with full force. Your most obedient servant,

Charles Hutton Gregory, Resident Engineer.

It was stated at the meeting that Mr. M. Ricardo, of Brighton, had constructed a model of a machine which appeared likely to be of use not only in such cases as were now more particularly referred to, but in cases of collision.—The model was here exhibited. It consisted of a strong frame-work, somewhat similar to the frame-work of a goods-truck, the area being filled with powerful springs, so arranged as to collapse upon the application of a strong impinging force, the effect of the blow being thus of course broken.—A small experimental railway has been constructed at New Cross station, for the purpose of testing, as far as a model could test, the efficiency of the invention.

THE ORIENTAL STEAMER.

Abstract of the Log of the Peninsular and Oriental Steam Navigation Company's Steamer Oriental, John Say, Commander, on her second voyage from England to Alexandria and back.

		Distance in Miles.	Hours under Steam. H.	M.	Remarks.
Out.	Falmouth to Gibraltar .	1,069	143	25	Tremendous gales during three days.
	Gibraltar to Malta	989	91	0	Fine weather, average speed. 11 knots per hour.
	Malta to Alexandria	827	83	15	Fair weather.
Home.	Alexandria to Malta ..	875	93	30	Heavy head sea.
	Malta to Gibraltar..	981	103	0	Fair weather.
	Gibraltar to Falmouth .	1,074	118	5	Heavy gales during three days.

Steamed, out, 2,885 miles, in 317 hours 40 minutes.
— home, 2,880 miles, in 314 hours 35 minutes.

Total distance, 5,765 miles, in 632 hours 15 minutes.

Lowest average rate of speed from Falmouth to Gibraltar, violent gales, 7½ knots per hours. Highest average rate of speed, 11 knots per hour.

IMPROVEMENT ON ECCENTRIC RODS.

Sir—A plan has long been desired for working the sliding valves of a locomotive engine with two fixed eccentrics, (that is one to each cylinder) so as to give the lead correctly when the motion of the engine is reversed, that is to say, when the engine is working either way. There have long since been locomotive engines constructed with only two eccentrics, and so as to give the required lead to the valves, when working in either direction: but these eccentrics used to work loose upon the shaft, and when the motion of the engine was required to be changed, their situations were altered, by means of levers and catches. But before these catches could get to their proper places, the shaft was obliged to be turned, nearly half way round at least, therefore, each engine was furnished with a set of rods and levers to enable the engine man to work each valve by hand, until the shaft came to the proper place for the catches to go together. This plan, in consequence of the tediousness in reversing the motion, its being so very liable to get out of repair, and other objections, has nearly fallen into disuse.

The plan now almost universally adopted, consists of four, all of which are firmly fixed to the shaft. These eccentrics are so arranged that two of them work the valves when the engine is going in the forward direction, and the other two work the valves when the engine is going in the backward direction. The four eccentric rods are all connected to one main lever, namely, the reversing lever, and by this lever two of the eccentric rod-ends may be attached to, at the same time the other two will be detached from, the levers which work the valves. With this arrangement the starting, and the reversing, of the engine are so simple as to be performed by the greatest novice; while with the former, the engine man requires considerable practice before he can get properly into the way of starting and reversing.

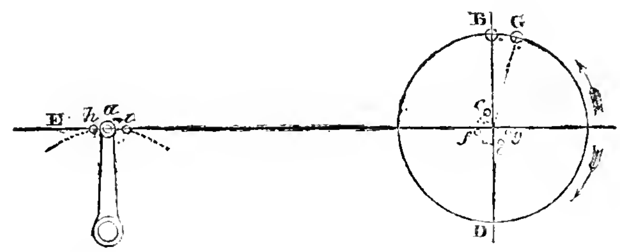
A plan for reversing the motion of the engine with greater ease, and for giving the lead to the valves with greater accuracy than that with four eccentrics, can hardly be desired; but it has long been the study of many ingenious persons to contrive a method from which they may obtain exactly the same result with *two fixed* eccentrics. This subject has, to my knowledge, been the cause of many experiments, some of which have by accident arrived pretty near to the point of correctness; but on their being performed upon a larger scale, in consequence of the persons engaged in them not being thoroughly acquainted with their ruling principles, they were deemed incorrect. There are those who have studied this subject so minutely, and made so many unsuccessful experiments, as to at last conclude it impossible to obtain this result in the manner alluded to. I have seen several ingenious diagrams intended to prove the impossibility, and I have even known attempts made to prove it impossible by geometrical demonstration.

I think it needless for me to enter into the details of the valve work, but, however, I will give you a short description of the method of setting the four eccentrics, which will refresh your memory with their principles, and at the same time perhaps, serve for as good proof of the plan I am about to describe, as can readily be given.

As the eccentrics, and all the other parts of the valve work, belonging to the one cylinder, are generally the same as, but quite independant of, those belonging to the other cylinder. And as each pair of eccentrics require to be set at exactly the same angle with their respective cranks, I think it will render the explanation much plainer, to only take into consideration the two eccentrics belonging to one cylinder, namely, one for the forward, and the other for the backward motion.

Suppose A B C D, fig. 1, to be a circle described by the crank, *a*, the lever to which the eccentric rods are to be attached, E C, a line drawn through the centres of the cylinder, end of the lever, and the crank axle, and B D another line also drawn through the centre of the crank axle, but perpendicular to E C. Suppose it to be at C. Now, when the crank is in this situation, the piston will, of course, be at the end of the cylinder; and the lead is generally considered as the distance the valve has moved from the middle of its stroke, or as the distance it is open, when the piston is in this situation. To give this lead, when the engine is working in the direction shown by the arrow F, the eccentric must be set about *c*; and the perpendicular distance from the line B D to *c*, is the quantity of lead in the eccentric. Now, when the rod belonging to *c*, namely, the eccentric rod, is attached to *a*, the valve will have the lead for working the engine in the direction shown by F, and it will continue to open until the crank arrives at G. But if the crank be turned in the direction shown by H, the eccentric will cause the valve to move in the wrong direction, and, consequently, allow the steam to act contrary to the motion of the piston; therefore, another eccentric *e*, is furnished, which is set at exactly the same angle with the crank as *c*, but on the opposite side. Both of the eccentric rod ends are connected with the reversing lever, as I have before observed, by which they may be detached from, and attached to the lever *a*, at pleasure. It will be seen, by a little attention to the figure, that the changing of the eccentric rods, when the crank is at C, will produce no alteration in the position of the valve, neither is it necessary it should, because the piston is then at the end of its stroke, and, although the crank be required to turn in the other direction, the steam will still be required to act upon the same side of the piston.

Fig. 1.



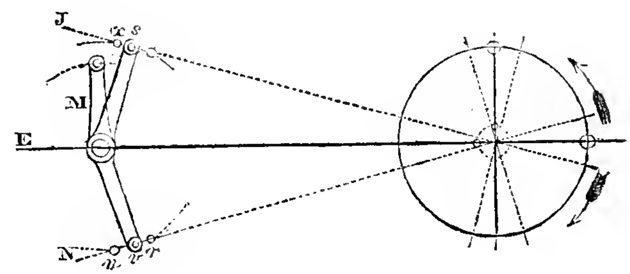


Fig. 2.

Let us now suppose the crank to be at B, the eccentrics will now be at *f*, *g*, and the piston about the middle of the cylinder. When the engine is intended to work in the direction of F, the rod belonging to *f*, must be attached to the lever, which will cause it to stand at *h*, and consequently the valve will be wide open, with the exception of the little difference caused by the lead. To reverse the motion, that is to say, to set the valve for working the engine in the other direction, the valve must be made to slide so as to open to the same extent, to allow the steam to act upon the contrary side of the piston. This is accomplished by the reversing lever, which detaches the rod belonging *f*, and attaches that belonging to *g*, which, by means of its forked end, draws the lever from *h* to *i*, and consequently causes the steam to act on the other side of, and force back, the piston.

By a little attention it may be seen that, while the crank is in any point of its revolution, the changing of the eccentric rods will produce that alteration, in the position of the valve, required to reverse the motion of the engine; therefore, I think the two points, in which we have supposed the crank, will be sufficient to explain the manner in which the lead is effected, and the motion reversed by the two fixed eccentrics to each valve.

I shall now proceed to explain the principles of a plan for giving the lead to the valves, and reversing the motion of a locomotive engine, with two fixed eccentrics, instead of four. In the following explanation, for the same reason as in the foregoing, I shall only speak of the valve, &c., belonging to one cylinder.

Suppose (as in fig. 1,) the circle A B C D, fig. 2, to be described by the crank, E C, a line drawn through the centres of the cylinder, and crank axle, and B D to be drawn perpendicular to E C. Suppose the crank to be at C, and the eccentric at *e*. After having determined the quantity of lead to be given by the eccentric, draw the lines F G, and H I, at the same angles with the crank, as you would set the eccentrics in fig. 1, to the same quantity of lead. Then draw the line J K, perpendicular to H I, and that end of the lever to which the eccentric rod is attached when the engine is working in the direction of L, must come in this line; supposing the valve to be worked from the lever M. By a little attention it will be perceived that, by setting the end of the lever in this situation, the valve will have the same quantity of lead, as it would if the lever and eccentric were set as in fig. 1. To cause the engine to be right for working in the contrary direction, no alteration is necessary in the situation of the valve; still it would not do to let the eccentric rod remain attached to *s*, therefore, I introduce another lever *v*, the end of which comes into the line N O, which is drawn perpendicular to F G, and, by means of the reversing lever, I detach the eccentric rod from *s*, and attach it to *v*, which will still allow the valve to have the lead, and also cause it to move in the proper direction, when the engine is working in the direction of P.

Let us now turn the crank to B. The eccentric will now stand at x. To cause the piston to work the crank in the direction of L, the eccentric rod end must be attached to the lever s, as before, which will cause it to stand at x, and consequently cause the valve to be wide open, with the exception of the little variation caused by the lead, as I spoke of in fig. 1. To reverse the motion, that is, to cause the crank to turn in the direction of P, I remove the eccentric rod end from x to r, and by this means (the eccentric rod end being properly formed) the lever will be drawn from r to n, consequently the valve will receive the same change as it did in fig. 1, by changing the eccentric rods, when the crank was at B.

By setting the cranks, in figs. 1 and 2, in any two corresponding points of their revolutions, it will be found that, when the eccentric rod in fig. 2, is attached to the lever s, the valve will be in the same situation as that of fig. 1, when the rod belonging to **c** is attached to the lever a. And it will also be found that the changing of the two eccentric rods in fig. 1, will effect the same change in the situation of the valve as the removing of the eccentric rod in fig. 2, from the one end to the other. Hence it is evident that one eccentric, with the two levers, arranged in the manner described, will produce the same effect, in every respect, upon the valve, as is now produced with the two eccentrics.

The distance s r, fig. 2, will depend upon the length of the eccentric rod, and the quantity of lead in the eccentric. If the eccentric be required to give a greater quantity of lead than common, it will perhaps be advisable to use two bell crank levers instead. But these particulars are of little importance, the principal object to be attended to is to set the ends of these two levers in the proper places.

I am afraid I am trespassing too far upon your pages, therefore I will conclude with a short explanation of a little deviation in this latter arrangement from the former, which, before, I did not think worthy of notice. When the crank is at C, fig. 1, either of the eccentric rods may be attached to the lever a, without moving it. But in fig. 2, when the crank is in that same position, it will be found that the eccentric rod cannot be removed from s to r, without making a little alteration in the levers. It would be a waste of time to enter into a minute explanation of this little alteration, which is caused by the vibration of that end of the eccentric rod which is in connection with the eccentric; upon the same principles as the piston is caused to be in the middle of the cylinder when the crank is at B.

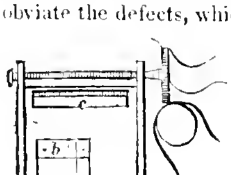
I remain, Sir, your's, very respectfully,

JOHN CHARLES PEARCE.

Leeds, Nov. 9, 1840.

IMPROVEMENT OF THE HYPSOMETER.

SIR—The ingenious little instrument for taking altitudes, invented by Mr. Sang and described in your last number, appears to me greatly deficient in one particular, and that is in the means of obtaining a level base line on which to conduct operations; the absence of this quality, indeed, renders it almost useless on uneven ground, and should the base be extended over a space of 80 or 100 feet or yards, the difficulty greatly increases; in this case, to trust to the eye for obtaining a level, would be out of the question; one might as well guess the altitude at once, as a quicker and equally correct method of arriving at the desired result; the instrument, therefore, if used alone, is rather contracted in its sphere of usefulness, an additional observation with a spirit level being necessary to obtain a near approach to truth. In saying this, my intention is not in any way to detract from the merits of Mr. Sang's invention; on the contrary, I confess myself much taken with it, and on that account have been turning over the scanty resources of a cranium somewhat obtuse, in hopes of finding something that might obviate the defects, which appear as such, in my humble opinion.



I would propose, therefore, the addition of a small milled-headed steel bar, an isosceles triangle in section, on which the instrument should be suspended; balancing itself thus, a base line will be obtained constant in its level; a cross wire over the aperture b will be necessary to complete the line of collimation. By these simple additions, altitudes may be taken with much greater precision, and the instrument will also acquire the properties of a level, sufficiently accurate for the purposes of gardening, for draining, or for levelling banks, and may be used generally except where great mathematical nicety is required.

Should you consider this modification, which springs from a dull man's brain, worthy a place in your Journal, it might, by chance, be turned to good account by some of your more intelligent readers.

Liverpool, AZIMUTH.

REVIEWS.

Companion to the Almanac for 1841. Knight and Co.

WE are requested to explain in our notice of the present volume of the "*Companion*," a most singularly unlucky and vexatious accident which has befallen pages 245 and 6, owing to the hurry with which the sheet containing them was made up for press, nor was the mistake discovered till it was too late to correct it by a cancel, the larger number of copies having previously been disposed of. Those of our readers, therefore, who may have happened to have already perused the architectural section, must have felt completely mystified by the descriptions of the Reform Club-house and the Corn Exchange, for they are so strangely intermixed and shuffled together, that it is utterly impossible to understand either as now put together by the printer, who has clapped down the saloon of the Club-house in Mark Lane, and *vice versa* put the newly modelled area of the old Corn Exchange into Mr. Barry's building in Pall Mall—which, it seems has been improved by Mr. Morris and decorated by Bielefeld. Perhaps this last rather startling piece of information may excite the architectural reader's suspicion, and satisfy him that there must be some mistake, although he may probably not be able entirely to unravel it,—or even if he can do so, to account for it—how by any possibility it could have occurred. In a monthly publication such a blunder would have been of much less consequence, because there the opportunity of rectifying it would have soon occurred, whereas a twelvemonth must elapse before the readers generally of the "*Companion*" can be satisfied that the architectural critic was not actually *muzzy* when he made his remarks on the two buildings in question.

The best way of correcting the mistakes will be to quote the passages where they occur. Speaking of the Reform Club-house he says: "We had imagined that the two smaller divisions both in the coffee-room and the drawing-room above it, would be separated from the other compartments into which those rooms are divided, by screens of —— columns, instead of which we now find that there are only attached columns at the angles of the projecting piers which form the breaks on the sides of those rooms, &c." Thus it will be seen that the latter portion after the —— in our quotation, and the rest of the article should be transposed from page 246 to the preceding one, and be connected with the line ending with "screens of." Which being done, the other blunder rectifies itself, it becoming obvious that the remainder of page 245, line 13 from bottom, belongs to the account of the Corn Exchange, where the paragraph now rendered unintelligible would read thus: "The order is an Italian Doric, the columns of which are so disposed as to form a parallelogram on the plan, having five intercolumns on each side, and three at each end, but in the upper part this shape is converted into an oblong octagon, the angles being cut off by the entablature being carried —— from the column next the extreme one to the corresponding column of the adjoining side. The attic and ceiling follow the plan of the entablature, and the second of them consists entirely of a very deep cove, through which the light is admitted by means of glazed compartments. The centre, however, or what would be the flat portion of the ceiling is neither glazed nor covered in at all, but forms an opening of thirty feet by ten (surmounted by a cornice and balustrade) consequently the shelter from rain is not altogether so complete as it might be."

Having quoted enough to correct the wholesale error on the part of the printer, by connecting the passages he had dissevered, we now proceed to make some remarks of our own, noting as a curious circumstance the alteration which has lately been made in the old or south area of the Corn Exchange, in order to shelter it from the weather, at the very time that a design has been adopted for the Royal Exchange, with an uncovered area or open cortile, surrounded as formerly by a covered ambulatory, which though protected from rain above, must be partially exposed to that, and to other inconveniences attending inclement weather—to damp, fog, and wind. We do not mean to say that Mr. Tite's design is at all more objectionable in that respect than were the others; on the contrary, it is far less so than the generality of them, on account of the very great depth, he has given to the colonnades. What strikes us as singular is that the Gresham Committee should have settled that very important point, for themselves beforehand, instead of allowing the competitors to have been guided as to it, by their own judgment. Had that been done the majority of them, we conceive, would have made their central area covered in,—unless deterred, perhaps, by the apprehension that it would be rejected as a new-fangled idea—an impertinent attempt to improve upon the former edifice.

The comments in the "Companion" on the Reform Club-house, will be best understood by referring to the ground-plan of that building, given in our last number; from which it will be apparent that by insulating the columns in the coffee-room, and placing them at some distance from the piers to which they are now attached, four colonnades or screens might have been formed with the same number of columns as at present. This would certainly have been attended with greater richness of effect, nor can we suppose that it escaped the architect himself; but it may possibly have been objected by the members themselves as tending to divide off the room too much, and to diminish its apparent spaciousness and extent. Yet—supposing this last notion to have been entertained, we consider it an erroneous one; for the appearance of extent would have been rather increased than at all diminished, by having a vista through a succession of spaces, one beyond the other—which would certainly have been more novel in character than the plan now adopted.

Of the new Church at Lee, Blackheath, which forms the subject of one of the cuts, a tolerably full account is here given, and it is spoken of as being greatly above the average quality of modern churches. Two circumstances are undoubtedly very much in its favour: one is that it has no side galleries; the other, that all the windows are filled with stained glass, "whereby a very unusual degree of richness and solemnity is imparted to the whole interior, so very different from that raw and garish, and we might almost say, 'worldly,' every-day light which prevails in the generality of our churches. These windows have been executed by Mr. Wailes of Newcastle, an artist who has here given proof of his study of ancient examples of the kind, particularly in the east window or windows, which have none of the gaudy, theatrical glare that is so offensive to good taste in many modern specimens of painted glass." Another specimen of superior design, here exhibited in an outline wood-cut, is the Catholic Chapel at Bury Lancashire, by Mr. J. Harper of York. The west front, which is the only part shown in the cut, displays exceedingly good taste, the design being composed of few features, but those well treated, and made the most of, so that there is, with much simplicity, a more than ordinary degree of richness, and boldness also. The octagon tower springing out above the gable, may be styled a novelty, although we believe that precedent may be found for it.

The Derby Arboretum, where Mr. E. B. Lamb was employed as the architect, and Mr. Loudon to lay out the grounds, is here noticed with deserved commendation, and as an instance of beneficially applied public spirit, on the part of its liberal founder Mr. Joseph Strutt, who seems to have very different notions of munificence from the late Sir John Soane. We hope that Mr. Strutt's noble example will not be lost upon others; for we are of opinion that public gardens and promenades of the kind are calculated to have a beneficial moral influence on the population of our towns. With this remark we take our leave of this new volume of the "Companion," which requires no farther recommendation from us than what we have already bestowed on its predecessors.

Schinkel: Werke der Hoheren Baukunst. Erste Lieferung. Potsdam, 1840.

It is somewhat premature to express any decided opinion as to this new and more costly series of designs by Schinkel, as this first Lieferung of the work contains only a portion of those for King Otho's Palace at Athens, nor does it comprise any letter-press. Still we are fain to make some remarks *ad interim*, both in respect to the general character of the publication, and the subject of the plates that have already appeared. It announces itself at first sight as an architectural *Prachtwerk*, and may therefore recommend itself all the more to some by its expansive size; but to many, we conceive, not only its size, but its shape will be objectionable, the form like that of the author's former series being an oblong folio, and this when opened extends to six feet! whereas had the upright form been adopted it would have opened only four feet. As regards the substance of the work, this is a matter of perfect indifference, yet it is a circumstance of considerable importance as regards its usefulness, because volumes of such ungainly dimensions and proportions are anything but convenient for reference, however well they may be adapted for occasional display; and at all events there was no occasion to enhance the inconvenience of size, by adopting the oblong shape, which last renders the work almost unfit for binding.

Whether many of the subjects are such as absolutely to demand plates of so large a size, we cannot at present tell. Probably there may be some interiors on a very large scale, but the subjects in the *Lieferung* before us, might have been just as well shown in plates of half the dimensions. For instance, the first plate exhibits a general elevation of the design for the palace on the Acropolis at Athens, and a section of the rock itself; but the buildings are on so small a scale that the whole of them do not occupy a space exceeding 20 inches in length by 4 in height, consequently a plate of half the size would have been ample enough. Besides, as the whole consists not of one uniform composition but of distinct ranges of building united together, the separate parts of the group might have been shown more advantageously on a much larger scale in one plate, by placing them one over the other, as is done in in the plate of the two sections. Unlike those in the '*Entwurfe*,' the elevation and the two sections are here shaded, and the former is coloured also; which we certainly do not think is any improvement upon the first work, for besides that the scale of the drawings is so small that shadowing renders their details indistinct: the elevation alluded to—which gives that of the remains of the Parthenon as seen before a part of the palace, consists of so many planes that pictorial effect is entirely out of the question, the whole having too much the appearance of a jumble. Neither is the colouring well executed in itself, being poor and washy, while the shadows are almost of a violet hue. Another circumstance which produces a more singular than agreeable effect, is that instead of being projected at an angle of 45 degrees, the horizontal shadows are so exceedingly broad that those of the cornices, notwithstanding that the latter have very little projection, extend to the lower facia of the architraves; which at first gives the idea of an unusually projecting roof. Colouring should, in our opinion, have been reserved for the perspective views and interiors. There is a larger outline elevation of one portion of the design, namely, of the façade of the Chapel at the south-west angle of the Palace, which enables us to judge of its style and details. It consists of a Corinthian monoprostyle, tetrastyle, projecting from the wider and loftier body of the Chapel, which like the portico itself is crowned by a pediment, and both pediments are enriched with sculpture. As there is only a lofty doorway within the prostyle, and the parts on either side of the latter are unbroken by windows, there is sufficient repose, and the advancing portico serves to give play to the composition. Yet if so far we are well satisfied with this elevation, there are other circumstances in it which are decidedly objectionable, the principal one of which is that though it is placed upon a lofty stylobate or platform, the ascent to the portico is by a narrow flight of steps in front, not exceeding the width of the centre intercolumn and the pillars forming it. Even in perspective the effect must be rather poor, and as shown in elevation it is quite disagreeable. Though their mouldings are sculptured, the cornices of the two entablatures are meagre in their profiles,—not at all distinguishable from Ionic; neither are the capitals marked by much of Corinthian luxuriance. We must confess that we are a good deal disappointed in the design generally, as here shown; for it does not realize the expectations we had formed of it, from what has been said on the subject of it by Quast, and the reviewer of his book, in the 35th Number of the Foreign Quarterly.

The combustion of Coals and the prevention of Smoke chemically and practically considered. By C. W. Williams. Part the First. Liverpool, Thos. Bean. London, J. Weale.

The object of this treatise is to show, on chemical principles, what errors are usually committed in the mode of burning coal in the furnaces of steam-boilers, and by what means the combustion of that fuel may be rendered the most perfect possible, and the formation of smoke effectually prevented. The style of the work is far from concise, yet, as the views therein set forth are based on sound principles, and their application (if found to be practicable, as asserted by the author) must be attended with great benefit, particularly to steam navigation, we confidently recommend it to the notice of steam engineers and others, to whom economy of fuel, and consequently the perfect combustion of coal, on the large scale of the furnace, is an object, being assured that the information gained will compensate for the *labour* of the perusal, although we think it might, with great advantage, have been condensed into one half of its present volume, if not less.

The author insists, with good reason, on the importance of attending to the chemical constitution of the fuel, and to the processes which go on, and the combinations which take place in the furnace during the progress of its combustion. He is, however, unreasonably fastidious with respect to certain received expressions, and frequently diverts the reader's attention from the immediate object of inquiry by ill-timed repetitions and observations, which render the perusal exceedingly tedious.

The 1st section treats of the constituents of coal, and the generation of coal-gas. In reading this, we were surprised to find that the author, who is so strenuous an advocate for accuracy of expression, even where it does not affect the facts considered, has himself, in one instance, made use of an inappropriate term, and that in a case where it has a tendency to mislead as to the main fact on which he is dilating. In the 22nd page he considers coal as consisting of two portions, viz., "the carbonaceous or solid, and the bituminous or volatile portions." Farther on he observes:

"The first leading distinction is, that the bituminous portion is convertible to the purposes of heat *in the gaseous state alone*; while the carbonaceous portion, on the contrary, is combustible *only in the solid state*;" and again,

"The bitumen of the coal, by reason of the great proportion of hydrogen which it contains, absorbs heat with great avidity, the first result of which is its change from the state of a *solid* to that of a *tarry, viscous, semifluid*; and, subsequently, by further increments of heat, to the state of gas, with its enormously expanded volume."

These quotations suffice to show that the gases which result from the application of heat to coal are considered by the author to be produced by a *simple distillation* of the bitumen contained in the coal, which suffers thereby no alteration in its chemical composition; whereas the truth is, that they result from the *chemical decomposition* of the bitumen, which, by the agency of heat, is resolved into a volatile portion, which is evolved in the gaseous form, and an excess of carbon, which remains behind in the solid state. Or rather, the coal should be considered as originally a homogeneous substance, which, by the action of heat, is first fused, and afterwards, when its temperature becomes sufficiently elevated, is decomposed as above. It will be evident, from these remarks, that the expressions "bitumen" and "bituminous portion" ought to be rejected, and "gases" and "gaseous or volatile portion" substituted in their place.

The 2nd section, which contains merely some general notions of gaseous combinations, is very tedious, and might, without detriment to the work, be omitted. We shall, however, just quote one specimen of the superfluous observations with which this work abounds. We read, page 36,

"Although, for the purposes of the *furnace*, so much value is set on the solid carbonaceous portion—the *coke*, we must not, on that account, undervalue the heat-giving properties of *the gas*. Indeed, the extent of those powers is strikingly brought before us by the fact that, for every ton of 20 cwt. of bituminous coal, no less than 10,000 cubic feet of gas are obtained, for which we pay at the rate of 10s. for every 1000 feet; the heating and lighting properties of the *gaseous portions alone* of one ton of coals thus costing five pounds sterling."

Is this fact a proof of the great value of coal gas as a heat-giving body? Certainly not; it is, on the contrary, rather an evidence of the great quantity of heat expended in evolving the gas, which is no advantage, but very much the reverse. This, however, is not the question; for, unless we are content to use coke from the gas-works, we must be at the expense of separating the gas from the carbonaceous portion of the coal, and all that remains to be considered is, what amount of heat is the gas, when separated, capable of evolving, how we can utilize the greatest possible proportion of that heat, and lastly, whether the amount gained is worth any additional expense which may be incurred in its attainment.

The 3rd section makes us acquainted with the proportions of carbon and hydrogen which constitute carburetted hydrogen gas, and with the quantity of oxygen necessary for the combustion of each of its constituents, as well as the quantity of atmospheric air which is requisite to furnish that quantity of oxygen. It should be here observed that the author has applied the term "atom" to atmospheric air, solely for the purpose of reducing the latter to an uniformity with the other gases concerned, being perfectly sensible that atmospheric air is not a chemical combination, but a simple mixture of oxygen and nitrogen gases, not exactly in the proportions required by the theory of chemical equivalents, the volume of the oxygen gas being 21 instead of 20 per cent. of the whole volume of air. This difference is neglected for the sake of simplicity. We have also to point out an error in page 51, lines 9, 10, 13 and 14, where "eight atoms of air" is put for "four atoms."

This section is followed by an explanation of two diagrams, representing the combustion of carburetted and bi-carburetted hydrogen, which present the volumes of gases used, and of the products of combustion, certainly in a very striking form, to the imagination of the reader, but we doubt whether a simple table of volumes would not have answered the purpose equally well.

In the 4th and 5th sections the author disposes of the questions of *the quantity of air required for the combustion of the carbon, after the gas has been generated*, and of *the quality of the air admitted to a furnace*. The 6th section treats of *the incorporation of air with coal gas, and the time required for effecting the same*, and the 7th of *the mode of effecting that incorporation in the furnace, preparatory to combustion*, which are very important points to be considered in the present investigation. In the latter the author explains the principle of his patent furnace, in which the air is introduced to the gases evolved from the coal by means of tubes pierced with numerous small orifices, the effect of which arrangement is compared to that of a blow-pipe.

The 8th and last section of this Part has reference to *the place or situation where the air may be admitted into the furnace*, so as to act its part with the greatest effect; and the conclusion arrived at is, for reasons therein developed, that the air for the carbonized fuel on the bars must come from the ash-pit, and that that for the gas must be introduced beyond the bridge.

Pambour on Locomotive Engines. London: John Weale, 1840.

(Second Notice.)

In our last number we were unable, for want of time, to give more than a very brief notice of this work, but we hope this month to make amends by analysing it throughout with that care which its importance deserves.

The mode of investigation adopted is briefly explained in the following paragraph, which we quote from the introduction of the first edition.

"The method constantly followed consists in taking, first, the primary elements of the question from direct experiment; then making use of those elements to establish a calculation in conformity with theoretical principles; and, lastly, submitting the results to fresh and special experiments, in order to obtain their verification. For the further elucidation of the formulæ, they are each time carefully submitted to particular applications; and, finally, to extend the use of the work to persons who may wish to find the results without calculations, the formulæ are followed by *practical* Tables, suitable to the cases which occur most frequently in practice."

The work is divided into 18 chapters, in which the various divisions of the subject are treated, followed by an Appendix, shewing the Expenses of Haulage by Locomotive Engines on Railways, from the Accounts of the Liverpool and Manchester, and the Stockton and Darlington Railways.

The first chapter is merely a description of a Locomotive Engine, and therefore needs no comment.

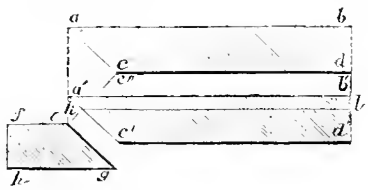
The second chapter, as we mentioned in our last number, is nearly a copy of the corresponding chapter of another work by the same author, entitled "*Theory of the Steam Engine*," a review of which will be found in the 2nd volume of this Journal, page 466. The present work contains, however, besides, in the 6th section of this chapter, a Table of 37 of the experiments made by the author with the view of ascertaining whether or not the steam left the Engine in the saturated state, that is, with the maximum pressure and density corresponding to its temperature, which experiments were merely alluded to in the above mentioned work. The results of these experiments are truly remarkable, since there is no exception to the perfect coincidence of the pressures, on the one hand, indicated immediately by the air-gauge, and on the other, calculated from the temperature marked by the thermometer. But, surprising as this coincidence is, we would by no means conclude therefrom, that such results were not actually obtained, being convinced of the fact which it tends to prove, viz. that the steam, after passing through the cylinder, leaves the engine in the saturated state; we would rather infer that the experiments were made with extraordinary care and with every precaution to avoid error.

The third chapter treats of the Pressure of the Steam, and Article 1. of the Safety-Valves in particular.

After explaining, in the 1st section, the mode of calculating the pressure according to the levers and the spring-balance, the author indicates, in the following section, the corrections to be made to the weight marked by that instrument. And here we cannot but express our dissent from the doctrine laid down with respect to the effect produced by the rising of the safety-valve on its surface exposed to the pressure of the steam. We read, page 90,

"......; but whenever the steam, being generated in greater quantity than it is expended by the cylinders, escapes with force through the valve, it raises considerably the disk of the valve: the consequence then is, that, instead of acting merely on the inferior surface of the valve, it evidently acts on a greater surface, and which is still greater the more the valve is raised."

It is to the latter part only of this proposition that we object. It is clear that the effective area of the valve must be augmented by its being lifted from its seat, and, if it is only raised a very minute quantity, merely sufficient to permit the escape of steam round the edge, the effective area of the valve will be increased from that of its lower to that of its upper surface; for in that case the steam, in passing through between the valve and its seat, presses against the whole conical surface of the former with sensibly the same pressure as exists in the boiler: but when the valve is raised considerably, as much for instance as twice its thickness, the steam, in escaping round the edge of the valve, will press on the conical surface of the latter with diminished force in consequence of the rapid enlargement of the space in which it is allowed to expand after having passed the lower surface of the valve. This will be evident on referring to the annexed dia-



gram, where $e\,f\,g\,h$ represents the valve-seat, and $a\,b\,c\,d$ one-half of the valve, in section, the rise $a\,e$ being equal to twice the thickness $b\,d$. Now it is clear that the steam will pass upon the lower surface $c\,d$ of the valve $a\,b$, and on the conical surface $e\,g$ of the seat with the whole pressure in the boiler, but that, after passing the contracted orifice $c\,e$ round the valve, it will immediately expand very considerably by reason of the rapid divergence of the surface $a\,c$ and $e\,f$, and will exert but a slight pressure on the conical surface $a\,c$ of the valve. But if the valve has only risen to the position $a'\,b'\,c'\,d'$, (supposing the rise $a'\,e$ to be very small,) the aperture for the escape of the steam becomes that represented by the line $e\,k$, at right angles to $e\,g$ and $a'\,c'$, so that the effluent steam will exert its full pressure, not only against the bottom surface of the valve, but also against all its conical surface from k ' downwards. On the upper part $a'\,k$ the pressure is but inconsiderable, as in the former case, so that the circle whose radius is $k\,l$ may be looked upon as a near approximation to the effective area of the valve; and it is obvious that this area is by so much the greater as the rise of the valve is less, which is in direct opposition to the law laid down by M. de Pambour. We should express the law in general terms thus:

When the valve rests upon its seat, its effective area is equal to that of its inferior surface, or rather of the orifice covered by the valve; when the valve first begins to rise, its effective area is equal to that of its upper surface; and, as it rises more and more, the effective surface goes on diminishing, but according to a law which remains to be determined.

We therefore consider the calculation in pages 90 and 91 as fallacious.

Before quitting the subject we shall just offer a remark on the paragraph which closes this article, which is the following:

"The above established calculation, then, is to be depended on only when the balance-screw can be lowered so as precisely to equilibrate the interior pressure, as has been said above, without, however, allowing the valve to rise. But the thing is not possible when the engine produces a surplus of steam beyond what its cylinders can expand, because this steam must necessarily have an issue. In this case, then, the pressure is to be found only by recurring afterwards to the barometer-gauge, as we shall presently indicate."

It seems the most natural hypothesis, that, the blowing of the valve is a sign that more steam is generated in the boiler than can be expended in the cylinder *without raising the pressure in the boiler*, and that the blowing may *always* be prevented by a suitable augmentation of the weight on the valve.

The second article, which completes this chapter, contains a full description of the four instruments employed by the author to determine the pressure of the steam, with an explanation of the mode of using them, namely, the *barometer-gauge*, the *air-gauge*, the *thermometer-gauge*, and the *spring-gauge* or *indicator*.

The fourth chapter treats of the Resistance of the Air, and we are sorry to find this subject not so fully elucidated as we had hoped.

The apparently anomalous result observed by Borda, and confirmed by M. Thibault, namely, that large surfaces experience a greater resistance from the air in proportion to their area than smaller ones, when submitted to a circular motion round an axis situated in the same plane as the given surface, was easy to foresee. But, as M. de Pambour has neglected to give the explanation of it, we shall do so, in order that those, to whom the true reason may not occur, may not reject the proposition as absurd. The explanation will be found in the following calculation.

Let a square surface whose side $= a$ revolve round an axis, situated in the same plane as the given surface and at a distance r from its centre. Let the velocity of the centre $= v$, and let $\rho =$ the resistance of the air against an unit of surface moving at the unit of velocity, and R the resistance on the whole given surface. The resistance on an element of the surface extending across its whole width, and at a distance x from the axis of rotation will be

$$d.R = \frac{a\,\rho\,v^2}{r^2}\,x^2\,d.x;$$

whence we obtain by integration

$$R = \frac{a\,\rho\,v^2}{3\,r^2}\,x^3,$$

and, putting for x its maximum and minimum values, namely, $r + \frac{a}{2}$ and $r - \frac{a}{2}$, we have, for the resistance on the whole given surface,

$$R = \frac{a\,\rho\,v^2}{3\,r^2}\left[\left(r+\frac{a}{2}\right)^3 - \left(r-\frac{a}{2}\right)^3\right]$$

$$\text{or} \qquad R = \frac{a^2\,\rho\,v^2}{3\,r^2}\left(3\,r^2+\frac{a^2}{4}\right).$$

The resistance on an unit of area will be found by dividing the total resistance R by the area of the surface, which is a^2. We have therefore, calling π the mean resistance per unit of area under the above circumstances,

$$\pi = \frac{\rho\,v^2}{3\,r^2}\left(3\,r^2+\frac{a^2}{4}\right) = \rho\,v^2\left(1+\frac{a^2}{12\,r^2}\right).$$

The term $\frac{a^2}{12\,r^2}$ shews that the above quantity increases with the ratio of the area of the surface to the square of the distance of the centre of the surface from the axis of rotation, so that, if this distance is constant the resistance per unit of area is greater for a large surface than for a smaller one, and that the same effect is produced by lessening the distance from the axis of rotation to the centre of the surface.

It is essential, therefore, as the author observes, that, when the circular motion is used to determine the resistance of the air, that the surfaces employed should be of very small extent compared to the length of the radius of rotation.

The following formula, to determine the resistance experienced by a body moving in the air at rest, is deduced from the experiments of Borda, Dubuat and M. Thibault.

$$Q = \cdot0011896\,\epsilon\,\Sigma\,V^2,$$

in which Q is the total resistance in lbs., V the velocity of feet per second, Σ the front surface of the body, traversing the air in a direction normal to that surface, and ϵ a coefficient which varies with the length of the body.

In applying this formula we must make

for a thin surface - - - - - - -	$\epsilon = 1{\cdot}43$
for a cube - - - - - - - -	$\epsilon = 1{\cdot}17$
for a prism of a length equal to 3 times the side of its front surface - - - - - -	$\epsilon = 1{\cdot}10$.

In the 2nd section the author has given a table of 6 experiments on the resistance of the air against trains. Five wagons of different heights, loaded with goods, were drawn to the top of the Whiston inclined plane on the Liverpool and Manchester Railway, and were allowed to descend by their own weight, first separately, and afterwards all united in one train.

The comprehension of this table would have been greatly facilitated if the author had given some fuller explanations of the manner in which he determined the last number in the 8th column, expressing the effective surface exposed to the shock of the air, which gives, for the five wagons together, a friction equal to the sum of the frictions of the five wagons separate. We have worked out the formula given in page 152 with different areas of effective surface, and find the friction amount to 5·92 lb. per ton with 144 square feet, and not 130, as given by M. de Pambour. The surface of the highest wagon, augmented by that representing the resistance of the wheels and screened parts of all the five wagons, is equal to 127 square feet, and as we have found the effective surface of the train to be 144 square feet, we must add $4\frac{1}{4}$ square feet per wagon, with the exception of the first, so that the effective surface will be found by adding to the area of the wagon of greatest section six square feet for the first, and $13\frac{1}{4}$ for each of the following wagons.

Assuming the value of V, or the velocity at the foot of the first plane to be correctly given by the question in page 148, we found that the hypothesis of any thing approaching to uniformity of motion could not by any means be reconciled with facts, but that by taking $\frac{4}{5}V^2$ as the mean for the first plane, and $\frac{9}{10}V^2$ for the second, the resistance of the air was correctly given by the equation we have quoted above. The square of the velocity at $\frac{1}{4}$, $\frac{1}{2}$ and $\frac{3}{4}$ of the length of the first plane are found by the above mentioned formula to be respectively equal to $\cdot 326\ V^2$, $\cdot 623\ V^2$ and $\cdot 864\ V^2$.

To simplify the calculation for general purposes a mean value of ϵ, namely 1·05, which is suitable to a train of 15 wagons, is substituted in the above formula, which thus becomes, when the the velocity is expressed in miles per hour,

$$Q = \cdot 002687\ \Sigma\ v^2.$$

This chapter concludes with a practical table of the resistance of the air against trains at velocities commencing at 5 miles an hour, and increasing by 1 mile at a time up to 50, the effective surface of the train increasing by 10 square feet at a time from 20 to 100. The resistance is expressed in lbs. on the whole train and on the square foot of effective surface.

Chap. V. On the friction of the wagons on Railways.

The only means of ascertaining the friction of wagons with any degree of certainty is by the circumstances of their spontaneous descent and stop upon two consecutive inclined planes. We therefore pass to the 3rd section of this chapter, which is an analytical investigation of these circumstances, as referring to a system of two wheels joined together by an axle-tree fixed invariably to each, and loaded with a given weight resting on a chair on which the axle-tree may turn freely.

"The inquiry comprises three successive questions: 1st. To determine the effective accelerating force to which the centre of gravity of the system will be subject in its motion; 2nd. To deduce from this the velocity acquired by the moving body at the foot of the first plane; and 3rd. To conclude finally the distance it will have traversed on the second plane at the moment when the friction shall have reduced its velocity to nothing,"

The motive forces applied to the system are first enumerated, in which the author includes, besides the motive forces properly so called, the passive resistances which oppose the motion, and which are generated by the motion itself. Among these there is one regarding which we think the author is in error, namely, the adhesion of the wheel on the rail. "It is this force," he says, "which produces the rotation of the wheel, by preventing its circumference from sliding without turning during the motion along the plane." This force is expressed by the weight T.

If this ought to be looked upon as a force, there must also unquestionably be an expenditure of power without any resulting effect at the fulcrum of every lever, for, as the above quotation proves, it is only in its capacity of fulcrum that the point of contact of the circumference of the wheel with the rail is here considered; what is called the rolling friction occupies the 6th and last place in the list.

It is a curious fact that this introduction of a false idea does not in any way influence the final result of the calculation: it serves merely to form an unnecessary intermediate equation, between which, and the principal equation when the quantity T has been eliminated, the resulting equation is the same as if that quantity had never entered into the calculation.

The two equations in question are

$$P \sin\theta' + p \sin\theta' - T - Q\ v^2 = \frac{P+p}{g}\ \phi,$$

$$\text{and}\quad T\ R - f'\ P r \cos\theta' - f''\ (P+p) \cos\theta' = \frac{p}{g}\ k^2\ \psi,$$

in which P is the weight of the chair with its load, resting on the axle-tree, p that of the wheels and axle-tree, θ' the inclination of the plane to the horizon, v the velocity of motion at any moment, $Q\ v^2$ the resistance of the air at that velocity, g the force of gravity, ϕ the effective accelerating force which produces the motion of translation of the system, ψ the effective accelerating force which produces the rotation of a point of the wheel situated at the distance 1 from the axle, $\frac{p}{g}\ k^2$ the momentum inertiæ of the wheel, R the radius of the wheel, r that of the axle, f' the coefficient of sliding friction, and f'' that of rolling friction.

Now the former, or princippal of the above equations ought evidently to have been

$$P \sin\theta' + p \sin\theta' - f'\ P\ \frac{r}{R} \cos\theta' - f''\ (P+p)\ \frac{1}{R} \cos\theta' - \frac{p}{g}\ \frac{k^2}{R}\ \psi - Q v^2 = \frac{P+p}{g}\ \phi.$$

Substituting $\frac{\phi}{R}$ for ψ, and 1 for $\cos\theta'$ as a sufficiently near approximation when the plane is but little inclined, and making

$$f'\ P\ \frac{r}{R} + f''\ (P+p)\ \frac{1}{R} = f\ (P+p),$$

we obtain

$$(P+p) \sin\theta' - f\ (P+p) - \frac{P}{g}\ \frac{k^2}{R^2}\ \phi - Q\ v^2 = \frac{P+p}{g}\ \phi.$$

Whence

$$\phi = \frac{g}{1 + \frac{p}{P+p} \cdot \frac{k^2}{R^2}}\ (\sin\theta' - f - \frac{Q}{P+p}\ v^2).$$

This is precisely the equation arrived at by M. de Pambour, page 145, which is transformed, for the sake of simplicity, into the following,

$$\phi = g'\ (\sin\theta' - f - q\ v^2),$$

the frictions represented by g' and q containing none but known quantities.

The accelerating force being equally represented by $\frac{v\ d\ v}{d\ x}$ (x being the distance traversed on the plane when the body has acquired the velocity v), this expression is substituted for ϕ, as well as b' for $\sin\theta' - f$, in the last equation, which thus becomes

$$\frac{v\ d\ v}{b' - q\ v^2} = g'\ d\ x,$$

which is the equation of the motion, and gives by integration between the limits $x = o$ and $x = l' =$ the length of the plane, calling V the velocity acquired at the end,

$$2\ q\ g'\ l' = \log.\ \frac{b'}{b' - q\ V^2},$$

whence

$$q\ V^2 = b'\ \left(1 - \frac{1}{e^{2 q g' l'}}\right).$$

This gives the velocity at the end of the first plane, and consequently at the beginning of the second. The question now is to determine at what point of the second plane the body will stop, to solve which we have, calling θ'' the inclination of this plane, all the other circumstances of the motion being the same as before, except that, the inclination of the plane being so much less, that the body is brought to rest, the accelerating force $\frac{v\ d\ v}{d\ x}$ is negative,

$$\frac{v\ d\ v}{d\ x} = -g'\ (b'' + q\ v^2),$$

— b'' being substituted for $\sin\theta'' - f$.

Making, after integration, $x = l''$ for the distance traversed on the second plane, and $v = o$, since the body is brought to a state of rest, putting also for $q\ V^2$ its value found above, we have

$$\frac{b'}{b''} = \frac{e^{2 q g' l''} - 1}{e^{2 q g' l'} - 1}\ e^{2 q g' l'}.$$

Finally, restoring the values of g', b' and b''; and calling h' and h'' the vertical heights descended on the first and second planes respectively, and making

$$Y = \frac{l'}{l''} \frac{e^{\frac{2qgl''}{n+1}} - 1}{e^{\frac{2qgl'}{n+1}} - 1} e^{\frac{2qgl'}{n+1}}$$

we obtain definitively for the value of the friction f,

$$f = \frac{h' + h'' Y}{l' + l'' Y}.$$

We have been involuntarily led, by the ingenuity of this method of eliminating the resistance of the air, into giving a complete sketch of the calculation, but we do not think it more than sufficient to give an adequate notion of its nature and perfection.

The fourth section contains an account of 12 experiments made on the above principle on the Whiston inclined plane on the Liverpool and Manchester Railway, with trains consisting of different numbers of wagons and variously loaded, the results of which are collected in a table at page 161.

From these experiments, the mean friction of the wagons, taken independently of the resistance of the air, amounts to $\frac{1}{389}$ of their gross weight, or to 5·76 lb. per ton: but to simplify the calculations, M. de Pambour takes it at 6 lb. per ton, which makes $\frac{1}{373}$ of the weight of the wagons. He remarks, however, that, except in cases of extreme velocity, the resistance of the air may be computed with regard to the wagon of greatest section alone, according to Borda, taking the friction then at 7 lb. per ton.

Chap. VI. treats of the Gravity on Inclined Planes, and Chap. VII. of the Pressure produced on the Piston by the action of the Blast-pipe. This is a very important point, and requires much more experience and careful investigation, in which the results of experiment are compared with the laws of Natural Philosophy, before it can be considered as satisfactorily settled. In comparing the last column of the Table of Experiments, page 193, with the last but one, we find some great discrepancies, although the coincidence is in some cases perfect or nearly so. For example, we find the pressure on the piston due to the action of the blast-pipe,

		Observed. lbs.	Calculated. lbs.	Difference. lbs.
in one experiment	....	5·0	3·6	1·4
in another	....	5·6	4·2	1·4
"	....	5·8	4·1	1·7
"	....	5·3	4·1	1·2
"	....	6·2	4·4	1·8
"	....	2·4	3·4	1·0
"	....	5·6	4·5	1·1
"	....	1·8	4·2	2·4
"	....	1·0	2·7	1·7
"	....	1·2	2·5	1·3
"	....	5·0	6·7	1·7
"	....	3·4	5·5	2·1
"	....	4·3	4·1	0·2
"	....	1·8	1·8	0·0
"	....	2·4	2·1	0·3
"	....	2·3	3·1	0·2
"	....	2·3	1·9	0·4
"	....	2·0	2·1	0·1
"	....	2·4	2·6	0·2
"	....	3·8	3·4	0·4
"	....	2·1	2·0	0·1
"	....	6·0	5·7	0·3

Out of 38 observations given in the table, the last ten of the above selection present the nearest accordance with the numbers calculated by M. de Pambour's formula, while the first 12 exhibit discordances too great to permit us to consider that formula as confirmed by the experiments alluded to. We must, however, content ourselves with these determinations for the present, for want of more accurate data, but we hope the invesgation will not be allowed to rest here, since the theory of the Steam Engine is not complete without it.

This chapter concludes with a *practical table of the pressures against the piston, due to the action of the blast-pipe*, which furnishes the means of taking this effect into account in some degree, which is better than neglecting it altogether.

In chapter VIII. the friction of the engines, both unloaded and loaded, is very ably investigated, and illustrated by experiments, and in chapter IX. is ascertained the definitive resistance per unit of surface of the area of the piston resulting from the various resistances estimated in the preceding chapters.

In chapter X. are presented the details of 22 experiments on the vaporization of locomotive engines, together with an inquiry into the circumstances which influence the rate of vaporization, which tends to prove, 1stly, that this is not affected by (the load on the safety-valve) or pressure of the steam formed, 2ndly, that it increases with the velocity of the engine, all other circumstances being the same. The author even goes so far as to conclude from those experiments which bear on this point that the vaporization of locomotive engines varies very nearly as the fourth root of the velocity. We do not feel justified in adopting such a law on the strength of so few experiments, which do not *all* concur even in establishing the general truth. That the velocity of the motion does influence the vaporization we are not, however, disposed to doubt; we only wish to intimate that more numerous experiments must be made on the subject before the law of that influence can be deduced. 3rdly, it is shewn from the experiments, three of which were made without the blast-pipe, that this appendage to a locomotive engine increased its vaporization more than five-fold, but that the narrowing more or less of the orifice of the blast-pipe produced no very remarkable result. It appears, however, that a certain area or orifice produces a maximum effect for each engine, that area being for the STAR engine, according to the experiments here reported, about 3·13 square inches.

In the 5th section of this chapter, which treats *of the comparative vaporization of the fire-box and the tubes, and of the definite vaporization of the engines per unit of heating surface of their boilers*, the author asserts, page 270, that, "during the active working of engines of a construction similar to that of the experiments, the two portions of the boiler vaporize, per unit of surface, the same quantity of water." This equality is ascribed to the fact of the flame being drawn, by the force of the blast, through the whole length of the tubes, by which means the whole of their surface is exposed to radiating caloric, but there are probably other circumstances which tend to equalize the two portions of the boiler as to their evaporating power, as for example, the superior conducting power of the thin brass of the tubes over that of the iron plate of which the fire-box is made.

In the 6th section an estimate is made of *the loss of steam which takes place by the safety-valves, during the work of locomotive engines;* but it does not appear that there are any positive data on which to found the assumption of the losses here assigned. The calculation is based on the rising of the valve observed during the experiment compared with the rise which is sufficient to give issue to all the steam generated during the complete close of the regulator, without regard to the pressure in the boiler, which must doubtless influence the loss through the valve considerably.

In the 7th section the quantity of water drawn into the cylinders in the liquid state is shewn to amount to a considerable proportion of the water appended: the average of the severe experiments in the table at page 289 is 24 per cent., and in one case it appears to have risen to 36 per cent. But as the determination of this quantity necessarily depends upon that of the loss of steam through the safety-valves, it must be affected by whatever errors there may be in the latter. We think it probable that the escape of steam through the valve is more copious than M. de Pambour calculates it to be; in which case the loss by *priming* would be found to be less considerable. We are, however, compelled, in this instance also, to content ourselves for the present with the data here furnished us. Besides, as we are possessed of the facts ascertained by experiments, we must take it for granted, that there is no great error in the total loss both by the safety-valve and by *priming*, as the only difficulty consisted in distributing it between these two causes.

The explanation of the manner in which a deficiency of steam-room in a boiler causes it to prime is not applicable to a locomotive engine for it does not follow, because that space is but 10 times the capacity of the cylinder, that "at every stroke of the piston, a tenth of the steam generated will pass into the cylinder," and that "the remaining steam will be all at once reduced to 9-10ths of what it was before." The truth is that there is no cessation either of the generation or supply of steam to the cylinders: the latter is at no instant more than once and 4-10ths as rapid as at another, and is at the least nearly 8-10ths of the average supply.

In chapter XI. the subject of Fuel is treated in a very scientific and practical manner, both with reference to the absolute quantity which locomotives of different constructions are capable of consuming, and also with reference to the consumption required to effect a given vaporization.

From the experiments on this subject, of which the particulars are given in the 1st section of this chapter, and which are grouped in a table, page 298, according to the proportion between the heating surface of the fire-box and of the tubes, the author concludes in the following section that the most advantageous proportion is as 1 to 9, or the total heating surface equal to ten times that of the fire-box; "since for a less proportion there would be increase in the expenditure of fuel, without increase of vaporization: and for a greater proportion, on the contrary, there would be reduction in the vaporization of the engine per unit of surface, which would incur the necessity of a larger boiler, and consequently of a greater weight, which it is important to avoid."

It also results from these experiments that, "according to the proportion of the fire-box to the total heating surface, the consumption of fuel in locomotive engines varies from 9·2 to 11·7 lbs. per cubic foot of *total* water vaporized; so that it may, on an average, be valued at 10·7 lbs. of coke per cubic foot of total vaporization."

It is to be observed that this *total* vaporization includes the loss by priming, so that the quantity of coke per cubic foot of water really converted into steam would be, according to M. de Pambour's calculation, about 14 lbs.

Of the 12th chapter, which treats of the Theory of locomotive engines, we shall merely observe that it is in substance the same as in "The Theory of the Steam Engine," to which work we have already alluded, but much more instructive with regard to locomotive engines, the peculiar circumstances of which are here discussed at much greater length. The application of the the theory is rendered easy by practical formulæ and examples, and its correctness corroborated by applying it to the results of a considerable number of experiments, collected in a table at the end of the chapter.

The theory is continued in chapter XIII., in the first 9 sections of which are solved the various problems which occur in the construction of locomotive engines, viz., to determine the vaporization or heating surface, the dimensions of the cylinders, and the diameter of the wheel, necessary for the engine to draw a given load at a given velocity; to determine the vaporization or heating surface, the pressure in the boiler and the dimensions of the cylinders, necessary for an engine to assume a given velocity or draw a given load, producing at the same time its maximum of useful effect; and lastly, to determine the combined proportions to be given to the parts of an engine, to enable it to fulfil divers simultaneous conditions. The utility of all these problems is too evident to require pointing out.

In the 10th section, which is an examination of the special influence of each of the dimensions of the engine on the effects produced, we have to direct attention to a slight contradiction. We read, page 417,

"Moreover, it will also be recognised that, for a given vaporization, the velocity will be by so much the greater as the factor $\frac{d^2l}{D}$ has less value. It is in consequence to be concluded that, in order to augment to the utmost the velocity of an engine with a given load, we must either employ a cylinder of the smallest possible diameter, or make the wheel the largest possible with reference to the stroke of the piston."

It is a more direct inference that we must employ a cylinder of the smallest possible capacity in proportion to the diameter of the wheel. We read further:

"These consequences might however have been seen *à priori;* for if we suppose a given vaporization in the boiler, it is clear that the quantity of steam which will result from it per minute cannot issue forth in the same time by a cylinder of less diameter, except on the condition of increasing its velocity during its efflux, that is, of increasing the velocity of the piston. As to the ratio between the length of the stroke of the piston and the diameter of the wheel of the engine, as it is known that at every double stroke of the piston the engine advances one turn of the wheel, it is readily perceived that the larger the wheel relatively to the stroke of the piston, the greater must be the velocity of the engine with a given load."

In all this reasoning the author has lost sight of the circumstance that a diminution of the capacity of the cylinders, *with a given load,* will necessarily demand steam of a greater pressure, and consequently of greater density, in the cylinders: but, as the density of steam does not increase in proportion to its elastic force, there will be a slight increase of velocity with the smaller cylinders.

A little farther on, page 419, we are told that the load which an engine is capable of drawing at a given velocity "is diminished by the values of d, l and D, that is, by the dimensions of the cylinder, the stroke of the piston, and the wheel, which are proper to augment the velocity of the engine."

We were at first puzzled for an explanation of this contradiction, but, on examining the two equations from which the above deductions were drawn, we perceived that the latter were not justified by them, but that the same values of d, l and D which would increase the velocity with a given load would also increase the load with a given velocity, the fraction $\frac{d^2l}{D}$ being *positive* in the *denominator* of one of the fractions, and *negative* in the numerator of the other. The error we have pointed out runs through the rest of the section.

(To be continued.)

Specifications for Practical Architecture, preceded by an Essay on the Decline of Excellence in the Structure, and in the Science of Modern English Buildings. By Alfred Bartholomew, Architect. London: John Williams, 1840.

We have so often made an attempt to examine this important work with the attention it deserves, that we fear we may be considered remiss by our readers in not attending to it before—the fact is that it contains so much matter intimately connected with the profession, that it is with difficulty we can select any one part in preference to another, a difficulty increased by the arrangement of the work. We have already, by permission of the author, given large extracts, which will be a sufficient testimony to our readers, that it is a work well deserving of the attention of every one connected with building, we will not say the profession alone, for it is equally as well deserving the notice of the public generally. Having said thus much, we must not be considered as agreeing with all the sentiments and opinions of Mr. Bartholomew, although we believe that what he has written, has been done in sincerity: we think that he has been too much imbued with the Wren-mania, and considers that nothing is now done equal to the buildings and architecture of the period previous to the eighteenth century—no doubt, many of our public edifices built during that period were executed with great judgment, but we know that many of them possess faults, nay very great ones; for how many of them do we find that have lossed their spire or steeple, and in others the piers of the main tower have given way, under the great pressure which they are made to carry. Nor do we find that all the buildings of that period were erected *fire proof*—we believe that very few of them have their vaulting of stone, some we have seen which so closely resemble stone, that they have been taken for that material until the visitor is told to the contrary. Although, during this period there were erected numerous ecclesiastical buildings, possessing architectural merit of the highest class, we should like to know how many buildings of a domestic character were erected, possessing any claim to architectural pretensions, in comparison with those which have been erected within the last century—now, the whole of a man's fortune is not placed at the mercy of the priest, for external pomp to support an intolerant church or to prevent the soul from going to purgatory: no, part of that fortune is now devoted to the erection of edifices, which form an ornament to many parts of the united kingdom, and we hope to see them still farther increase.

Another part of Mr. Bartholomew's bewailing is on account of the use of Bath stone and cement; no one will dispute that if you can obtain funds sufficient, that it is far better to use Portland stone, but the immense cost of labour on that material is a bar to its general introduction, and it is on account of the cheapness and facility in the use of cement for giving architectural character to our buildings, that it is so largely introduced. We believe that the fault in the use of it is by allowing the workman to have cement of an inferior quality, or in permitting it to be employed by men that do not know how to mix or apply it.

That part of the volume which treats upon Specifications, possesses some very useful hints for those who are not well conversant with that branch. We feel ourselves very strongly inclined to recommend that specifications should at all times be drawn up by parties who will make it their peculiar study; such a person would be of as much service to the architect, as the special pleader or equity draughtsman is to a lawyer.

The information on construction will be found valuable to the student, who will do well to peruse attentively the general contents of the volume.

We think the work would have been clearer had it not been split up so much into chapters and sections, which however convenient for reference, are embarrassing to the reader. This is even carried out in the specifications, so that a specification is interrupted by chapters and sections. We must not, however quarrel with Mr. Bartholomew, for he is too steady a reader of the Journal not to enlist our sympathies: some of our correspondents however seem, by the remarks in his work, to give him a good deal of trouble. He devotes especial mention to Candidus. We must now leave Mr. Bartholomew, and his work with a hearty commendation to our readers for its usefulness.

THE ARCHITECTURE OF LIVERPOOL.

By a Stranger.

Not deeming myself bound to continue these remarks according to any fixed rule, I shall merely note each of the "Architecture of Liverpool" as comes first in my way, during my peregrinations through the town, without regard to their proximity to each other or even their relative importance. I shall, therefore, now turn my face towards the place where the wise men of old came from, namely, the east, and make a few remarks on the Railway Station. This is a mere screen, little better than a blank wall, hiding, instead of setting off, the great works that are going on behind it. It is a long, low, flat facade, broken into many unmeaning parts, without end or aim, having six and thirty engaged columns very nearly in a line, like a regiment of soldiers leaning against a wall, set upon pedestals, and supporting an entablature, and over the centre and side entrances having heavy masses of stone-work. This station is a great failure. Instead of being a grand substantial gateway, suitable to the commercial dignity of this great town, and the incalculable importance to mercantile men of railway transit,—instead of an entrance suitable in height and dignity to so important an object, which, by its outward appearance, should tell of the great things going on behind it, and thus serve as a title page to its contents, here is a long, low wall, ornamented, it is true, with columns, &c., but still giving no one any idea, by its outward expression, of its nature or intents. Every edifice should express its object. A church should display gravity and dignity, a theatre lightness and gaiety, a prison rude majesty and sturdy strength: in short, every edifice should, like the countenance, express the spirit. But, in this erection, besides this want of expression for the intended object, the thing is not good in itself. The expression of a column is that of support to something superincumbent. But what do these support? Why, they are themselves stuck against a wall where they are not required, for, we naturally suppose, a wall can support itself; and over them is an entablature, which might, also, have been supported by the said wall. Moreover, this entablature is in itself but indifferent, and it is broken into petty parts, wanting that continuity of outline so necessary in large edifices for effect and dignity; and all this is to no useful purpose, but merely to hide the railway. How much better would it have been to have made these now useless columns available, and placed them at the outside of the pathway, thus forming a colonnade, for shelter from sun and rain, with bold but unbroken entablatures; and, in the centre, made a very large and handsome gateway, worthy of the town, somewhat similar in style to those of Birmingham and London, albeit they are not quite faultless. But I must, in justice, add, that the columns are well wrought and proportionate, the mouldings good, and the basement and pedestals bold, substantial, and somewhat original.

One of the most important architectural edifices in the town, as well from its size and prominent position as from its cost, is Saint Luke's Church, which crowns the summit of a gentle ascent, and forms a beautiful termination to the view at the south-east end of Bold-street. It is one of the finest and most picturesque buildings of its kind in the county. This has been a most successful attempt at the opprobriously termed Gothic, a name sarcastically applied to the sublime architecture of the middle ages, by Sir Christopher Wren, whose own tasteless attempts in that style show how little he understood the artist-like feelings or the grand conceptions that enabled the monastic architects to raise edifices remarkable for boldness, scientific construction, and that fascinating and almost magical effect of chequered light and shade, which, combining, at times, the most playful effects, as in their small oratories and chapels, and, at others, the most sublime and elevating, raising the feelings of the devout, and appalling even the infidel, produced architectural effects that have not been equalled even in the present day of knowledge and enlightenment. St. Luke's Church consists of a nave, chancel, and tower. The details of the exterior of this church are exceedingly good, and show that the architect had a chaste appreciation of that style. The windows, battlements, buttresses, pinnacles, &c. are almost all unexceptionable, which, with the admirable tone of colour in the stone, produce a very fine effect. The chancel is a copy of the Beauchamp Chapel, at Warwick. This chancel, though beautiful enough in itself, looks sadly likely an excrescence or after-thought, tacked on to the main building, which idea is still further kept up by the difference of style, which is of later date than that of the nave. Why should this have been done in a modern edifice? Why, in an edifice built at the same period, combine the incongruous styles of several periods? for, in the Gothic style, there are many eras, each characterized by certain distinct features essentially different from all the rest: and thus the antiquary may trace the date of erection of almost any ancient building to within a very few years. It may be replied, that there are remains of many buildings of different styles. True. But the reason is, that they were built at different periods, each in accordance with the style of its own date, thus creating a great jumble of styles, often picturesque, but rarely chaste or correct, or forming one homogenous mass. Nor can any one produce a single ancient edifice built at the same period but in different styles. Thus we plainly see, that this mixing of styles is neither in accordance with reason nor the beautiful examples of antiquity now remaining unto us. The tower of this church is square, with turrets at each angle running up, and finishing with small battlements. The lower part contains a deeply-recessed doorway, with bold shafts and mouldings. Above is a "*perpendicular*" window, which is somewhat disproportionately short. The clock, in the centre of a row of panelling, comes next, and then the belfry-window, of *decorated* character, being filled with flowing tracery. The upper part of the tower is finished with a profusion of graceful panelling, and terminated with perforated battlements of chaste design. The whole is exquisitely beautiful and picturesque: nor do I know any *modern* tower which has so fine an effect as this. Whether the sun shines broadly over its top, as it stands boldly out against the clear distant blue of the sky, or clouds chequer the face, the effect is equally beautiful, combining fair proportions with the chastest details. But there is, I think, one anachronism that, to an antiquarian eye, mars the whole: it is like the mole upon the fair face of some otherwise exquisitely beautiful girl. The lower window is of about the date of 1450, that of the upper one about 1370, and is copied, I suspect, from one in Worstead Church, Norfolk. Therefore, even if the tower were built to imitate different periods, which I can hardly imagine, they have placed the oldest style upon the top of the more modern one; so that an Irishman might blunder upon the idea, that they had commenced building at the top, and gradually travelled down to modern times. One has heard of "building castles in the air:" surely the architect of this edifice intended to illustrate the saying. The ground on which this edifice is built being much higher at one end than the other, the architect, by way of obtaining a level, has constructed a large and handsome flight of steps, though somewhat too high, at one end, occupying the whole width of the edifice. This gets over the difficulty: but, although this may be a beauty to a Grecian temple, which was always placed upon the uppermost of a flight of steps surrounding the building, it is inconsistent with this style of architecture, and but few examples remain of such, except here and there upon the continent. Of the interior, with much that is good, there is much that is indifferent: the details are often excellent in design, but poor in execution, not having sufficient boldness or projection. The cornice from which the roof springs, especially, is much too small, the bases of the piers are miserable, the shafts against the outer wall, supporting the aisle roof, are poor and thin: but yet, with all these defects, in consequence of the excellence of other parts, the absence of that great defect in Gothic architecture, side galleries, and the expense lavished upon the whole, there is an effect produced that is highly pleasing, and renders the *tout ensemble* of this edifice one of the finest of its kind in this county, if not in the country. The entrance gates are much too small and unimportant, and resemble the upper portions of pinnacles cut off and placed there, and are, besides, much too numerous. How much better would have been large, bold, and handsome piers, or arched gateways, than these expensive frittered pieces of gingerbread, which must, altogether, have cost many, many hundred pounds.

Few things more strike a stranger's notice, or give him a better idea of the wealth of this most wealthy town, than the number and excellence of the banking-houses. To offer remarks upon a very small number would extend these papers too far, but there are two just completed that may be worthy of notice, viz., the North and South Wales Bank and the Union Bank. The former is one of the handsomest in the town; but, in criticizing any architectural work, the critic should make himself acquainted with the peculiar circumstances under which the architect was placed, and endeavour to discover what control they exercised over his design. Upon a cursory examination of this bank, it is evident the architect had to contend with difficulties of no mean order, such as his ground being irregular in shape, and, also, the necessity of getting sufficient accommodation within a very confined space, thus compelling him to obtain in height what he wanted in superficies; and, yet, here are enormous difficulties overcome, and a handsome edifice, in conclusion, remains. The entrance front consists of a Corinthian portico, *in antis*; the columns, which are very rich and handsome, being just disengaged from the wall and set upon pedestals, the whole being surmounted by a pediment, with rich cornice, &c. There are, in the centre, a doorway and two windows, one above the other, but the ornaments of all these are inferior to the rest of the work. The side consists of a row of six pilasters and three tiers of windows, the lowest range having three, circular-headed, with keystones, the place of the other two being occupied by narrow doorways. This building is too high, the entrance too narrow, the doorways, columns, and pediment cramped: but, it is also evident, the architect had no control over these: it was the stern necessity, arising from want of space. This must also excuse the narrow doorways of the side, although it will not do so the swelled frieze over it, a licentious practice, made use of in few buildings of importance, except the Temple of Bacchus, near Rome, the Basilica of Antoninus, and afterwards by Palladio, in the Rotunda of Capra, and a very few others. The cornice of this building is remarkably fine, and, in the order of its mouldings, resembles those of the Temple of Jupiter Stator, in the Campo Vaccino, the whole of which is considered to be the finest specimen of the Corinthian order in the world. One regrets, that want of means, or some other cause, prevents the least exposed sides of this edifice being finished in the same style as the two principal fronts, thus preventing that unity so essential to classic beauty.

The Union Bank, corner of Fenwick-street and Brunswick-street, has just been completed, and, although it is but a small edifice, I regard it as one of the completest, of its size, in the town. The front has two chaste Ionic columns, *in antis*, upon a high plinth, surmounted by a pediment, in which are some very bold and admirable carvings, whilst the frieze that surrounds the edifice is ornamented by handsome carvings of flowers, honeysuckles, &c. The cornice is plain and good, and is surmounted by carved pedestals and handsome parapets. Under the portico, also, are some very handsome illustrative carvings in high relief. The side is plain, but chaste, the windows simple and original, and all the details excellent.

After viewing these and many other buildings of the same kind, I inquired for the edifice in which the branch portion of the business of the Bank of England is transacted in this town, naturally expecting an edifice worthy of this great establishment, the profits it is reaping in the town, and the spirit shown in the erection of so expensive a one in London. But what was my astonishment and disappointment on being shown a poor, little, paltry, pitiable place, in Hanover-street, where there is neither beauty outside nor sufficient space in; some places dark, and all botched, inconvenient, and defective! Surely, the leviathan of Threadneedle-street will not be outdone by the pettiest banking-house in Liverpool.

A stranger is also justly struck by the number, size, and excellence of the Market-places here. The Fish Market is admirably suited to its purposes, and the entrance to the Fish Hall presents a very quiet, plain portico, expressive of its object. The St. John's Market, which is, I believe, the largest in this county, has no external beauty, as it consists, in front, of a mere brick wall, with stone entrance archway, with a column on each side and entablature over them. But, upon entering, one who has never been there before is much struck with the width, height, and length, the span and construction of the open roof, which, by constant repetition, as the eye looks down the long perspective of distance, has a curious effect. There are fine, broad avenues, supported and divided by numerous tall, slender pillars, to the eye all trending to the same point in the extreme distance, affording a beautiful practical illusion of perspective, whilst the admirable mode of lighting it gives, at certain times during the day, when the sun is brightly shining through the windows, an aerial effect of light and shade, and, in the distance, a dim atmospheric effect, that have been often admired by artists. All this, with the fair faces and rich dresses that are to be seen there, on market mornings; the luscious display of apricots, peaches, and other fruits; the beautiful bunches of flowers, of every kind, opening their petals to the day, and spreading around a delightful perfume; with the coolness and shadyness of the place, and the clean appearance of the market women, so different from those of Birmingham, London, or elsewhere, renders it, though but a market, a place where the stranger may well spend an hour's stroll.

EDER.

(To be continued.)

ON THE STYLE OF INIGO JONES.

We feel delight in reviewing the merits of a master, for as pupils of design we are interested in whatever concerns the history of our art: but we are more concerned in the criticism, when that master is an Englishman, and that art our country's. There is another interest involved in the investigation: because in descanting on style, we too often pass over beauties and originalities, where the prevailing sentiment is evidently borrowed. There is a disposition about us, to wave that patient investigation of the detail, under which the independance even of the borrower appears. Thus we say, in allusion to Inigo Jones, that his style is Palladio's. Certainly, there is the same modification of the orders, and the same appropriation of effect, perhaps the same selection of the parts. Certainly his style is Palladio's, if we except that, upon which the very groundwork of the Italian reposes: viz. the skill of assorting and applying, materials already furnished. But then he extracts no more from Palladio, than the poet does from nature, namely the elements and the matter. Indebted to Palladio he is, as the poet is to nature, for the picture displayed, but indebted he is also, to his own exquisite perception, for the soul which can encompass, and the hand which can pencil anew, its beauties in fresh combinations. He does not merely either leave Palladio full of the impressions of that master, but betrays the critic too: arrested by the elements, as much as by the effect by the parts, as much as by the whole. Such and such only, is the connection of the English master with the Italian: and if the latter deserve the homage of the southern school, so also does the former merit the praises of the northern. And if Palladio be recognized as the father of combinations, so should Jones be seen original in his conceits: whilst both appear like distinct geniuses of music: making the instrument of design to arrest the mind, solely by the exquisite beauty of their creations.

To follow Inigo Jones however in his arrangement, let us take him in one of his grandest flights, where the combinations are most extended, and the distribution most difficult. Suppose the front of 720 feet in the design for the Whitehall Palace. To distribute so long a front, and to bestow upon it the necessary gradations in effect, required several vast features in the first place: so the wings and the centre are made distinct, in plan, profile and elevation. The centre being the abode of dignity, and a focus for the eye, this is elevated above that contiguous to it: the wings too are elevated, and here the variety is first in the proportion, with the regulating principle an increase of the parts as they distance from the eye. For had not a tower terminated the façade, the eye would have fallen, and had not shadows been cast from the wings, tameness and indistinct blending might have resulted. Having resolved on general distinctions, Inigo Jones appears on a more intricate field, and here it is more important to follow him, since here it is he rises above, and surpasses his imitators.

First let us approach the centre, which though varying from others of his design, illustrates, the peculiar artifices of his style. It is not enough, be it observed, that the rusticated base which extends throughout, should here be stopped; and that pedestals and their huger columns should rise, unbroken by an inferior part to the first cornice. There is a fresh arrangement of variety yet to be considered. The centre betrays infinite attention and careful study. He seems here to have so diffused his features, that considered in itself and isolated from the main building, it would yet betray an unity in its design: unlike many of his followers who scatter their unity throughout the whole. Although the heighth of the centre is very little more than its width, the eye is yet insensibly led upwards to the tympanum which crowns it: and this not so much from the existence of that tympanum, as from the minutiæ. Nothing flat or depressed intrudes, the eye sweeps upon the arched entrance to the arched window above; and from the arched window to the figures which recline thereon. The angle made by those figures would meet in the base of the shield; whilst from the shield you at once forsake for the statue. Another glance however and fresh contrivances appear. The side compartments of the centre, in obedience to the idea of a pyramid which seems to float in Jones's mind, must not conduct you too hastily to the apex: because if so the principle of pyramidal truth would vanish. To avoid this error then, and yet still to admit of that gradual tapering, which in a pyramid is regular and unbroken, from the base to the summit: he has contrived in the side entrances, that their arches should conduct the eye, not to the tympanum, that would be sudden; but to the crown of the grand central arch: for if a line be drawn from the springing of the lesser arches to their crown: they would intersect in the crown of the greater arch. Then again, as if afraid that this were too sudden an ascent of line so near the base, he introduces two square panels over the lesser arches, as a relief to restore the balance, as it were of form. On the upper story the same idea exists, and the intersecting line of the lesser tympanums is in the centre of the head from which a festoon of flowers droop. A further scrutiny might still reveal increasing artifice in composition, but enough has been said for the merits of the centre. It will appear evident, I humbly believe as the criticism proceeds, that Jones surpasses all his imitators in that attention to the subordinate parts of his edifice. And this, be it remarked, is no trivial allowance to make, when the very elements and basis of Palladian doctrine, is combination; and that not in mere generalities, but in every part where consistency will admit a feature. Leaving the centre for the void, contiguous to it, there appears nothing peculiar to him from the rest of his school. The piers between the windows are twice the windows' width, whilst the windows are twice their height. The effect of this part, and its sober appearance is more to be considered in connection with the edifice as a whole, than as individually remarkable: except we notice the ornaments over each pier on the crowning blocking course: and which directing the eye upwards forms for it a kind of imaginary pyramid with each pier, whose ideal base is level with the top of the upper window. Advancing towards the wing, a part appears, contrasted with the void, from its heavy masonry, and then again relieved by its columns and statues. Here again the eye is courted centrally—(as if afraid that it might grow weary and fail) by its travel along the front. Four columns only are crowned with statues; the central window only have ballusters, whilst the roof slightly rises, to assist. Whilst here too the ornament, appears more abundant, and the superficies more enriched. The windows are richer, their dressings less plain. Trusses occur, breaks obtrude, and a ballustrade surmounts. Once more hasten on, and the wing salutes you, in its similarity to the centre, you admire the contrivance of Inigo Jones to protect the unity of this vast front. There you encounter a principle of optics though differently applied. The increased distance of the wing from the centre, exacts and increased importance in its composition, and proportionate to that distance, to recover the unity. It is made somewhat to resemble the centre, in its minutiæ, and thus the link of harmony is connected.

Looking back once more at the façade as a whole, we recognise a hand overcoming, rather than overcome by, the materials of his art. The perspective is also worthy of his notice, so that in whatever way you regard the edifice, its vast proportions and its more elegant reliefs are exposed to view. In the long and difficult front it is, that Inigo Jones is more marked and peculiar. That complication of parts, that ever varying distribution of the features, are peculiarly his. Others may appear on a smaller field equally happy, and yet cannot approach him in the grand and more extended scale. Like true genius he seems increasing in beauty and effect, with the increasing necessities; and extended nature of the design. As spectator of the structure, you are pleased as much by the intricacy unravelled as by the variety subdued. Nature with him is ever found under veil of art. But he is the painter of its gayer effects, whilst others on the contrary, represent its more sober appearances. If you take a critical survey of his designs you discover first the sketch, the outline and the shadows; and in this only *equal* to his school. But as a Watteau and Ostade gather a name from grouping the same figures, which otherwise exhibited were poor and tame, so Inigo Jones, by a consummate skill in assorting his, stamps his name upon the edifice. With the same cornice, architrave, ballustrade, figures and pediment, as others employ, a very different arrangement appears. If his front be short, you see this more particularly. He destroys the stiffness of outline by the detail. His decorations are sometimes sweeping and reclining in their form; and it was a desire to avoid the rigid line in ornament, that taught him to break the tympanum for the introduction of a wreath or a shield. If the wings are raised (which with him is usual when the centre is much depressed and the main body of the building long), he seeks to relieve, by a depression of form (very frequently) in the decoration. The architrave sometimes sweeps into width towards the base, as in the wing of Wilton House. He seldom employs one uniform unbroken ballustrade in the middle part, along the whole length, unless there has been a paucity of reliefs below. In Wilton House too we see this. If however the front be long, and the design a mansion, the various *parts* assume the varied forms, and together with the detail unite their effect: the various points of the building in this case assume an inclination in form as they soar up and encounter the sky. That is, they exhibit no harshness in their outline, or very little. He seems to unite with Wren in opinion and taste, and to mould the figures into spheres and sweeps as they stand against the sky. It is this which regulates him even in the ballustrade vases and globes that crown the cornice. It is something of this which directed a pediment on the wings of Wilton House, for it leads the eye in breadth, as a balance to the loftiness of the wing, and avoids the harshness of the horizontal. It may be admitted that this disrelish for harshness often led him into extravagance in composition, and caused him to exhibit in his smaller studies, a richness and exuberance more fitted for an interior. It may be admitted too that a certain want of severity in taste and coolness in adjustment, led him to trespass beyond what his more careful rival Burlington dared to allow. Often he may appear omitting the necessary members from a cornice, omitting the frieze, and introducing double plinths; still that richness of the artist, snatched from Italy is a charm entirely his own. In conclusion, it must be allowed, that Inigo Jones, gives a finish both picturesque and lively to the building, and brings into his design not only the orders and sentiment of Palladio, but the creations of an active fancy and the richest pictures of ideal taste.

FREDERICK EAST.

December, 1840.

ON THE RELATION OF HORSE POWER TO TONNAGE IN STEAM VESSELS.

SIR—It is a disputed question whether a large or small horse power of engines, is best adapted for sea-going steam vessels.

Without entering into the discussion, I will lay before your readers the tonnage and power of some of the finest ocean steam ships yet built; which table shows some curious contrarieties.

Vessels name.	Tonnage.	Horse Power	Proportion of tonnage to power.		Remarks.
				Tons.	
Acadia†	1200	440	1 h.p.	$2\frac{3}{4}$	Exceedingly fast.
Oriental	1670	440	1	4	$10\frac{1}{4}$ knots when deep.
Great Western	1340	450	1	3	
Great Liverpool	1543	464	1	$3\frac{1}{3}$	
British Queen	2016	500	1	4	Fast when light, and light stern breeze.
President	2366	540	1	$4\frac{1}{2}$	Slow under any circumstances
Liverpool (before alterations.)	1150	404	1	$2\frac{1}{2}$	Slow and crank.

In the above table I have endeavoured to place the vessels in the order of speed—an average westerly passage across the Atlantic being supposed to be the work performed. The "Oriental" and "Great Western" are, I think, about equal—as also the "President" and "Liverpool" (before alterations).

It will be observed that though the proportion is the same both in the "Oriental" and "British Queen," yet it cannot be questioned that on every point, and most especially when the vessels are deep, the "Oriental" has the advantage.

It may also be mentioned that the "Liverpool" has had seven feet more beam given her, and is now 393 tons larger than formerly; the proportion of power has, therefore, been *decreased*, whilst her speed and weatherly qualities have been materially *increased*.

Also, the four first and best vessels, and which vary least in their speed, in bad weather, have more beam (in proportion to their length) than the other three.

It appears to me that more depends on *the form and construction of the vessel*, than on having a large engine power.

I am, &c.

E.

Manchester, Nov. 30, 1840.

TABLE OF PORTICOES.

SIR—Mr. Dyer has pointed out what certainly looks like a very stupid blunder in the Table of Porticoes from the Penny Cyclopædia, and I was at first rather alarmed by his note, for he says that the portico of the Victoria Rooms is therein stated to have five intercolumniations (intercolumns), although placed in the octastyle class. But, on turning to the table itself, I find he has misconceived what is said in regard to that portico in the column of remarks, where it is further described as being "unequal diprostyle, recessed, five intercolumns," that is, recessed within for the space of five intercolumns, or corresponding with five out of the seven intercolumns of the octastyle in front. Perhaps the sense would have been clearer had the comma after "recessed," been omitted, or had "for" been substituted instead of it. But brevity was indispensable; and, in fact, that portion of the table was considerably abridged after being set up, in order to get rid of many *turn-overs*, and reduce it almost entirely to single lines. And thus it happened that the words "sculptured pediment," which were in the first proof, were struck out in order to save a second line. Other remarks underwent similar curtailment in several instances, for else the table would have occupied an entire page of the Cyclopædia. So far, however, from complaining of this, I rather feel grateful for so much space, and so many illustrative wood-cuts, being afforded me in that publication for such an article: because, although both fell far short of what I should have taken, had I been left entirely to myself, they exceeded what I could reasonably expect.

In these five vessels the variation of horses' power is only 24: the difference of tonnage 520!

† The remarks on the "Acadia" equally apply to her sister vessels, the "Britannia," "Caledonia," and "Columbia", and constitute a good example, as little difference is found in their performances, all the four being remarkably speedy vessels.

Mr. Leeds's note has afforded me an opportunity of explaining these circumstances, and accounting for, what I admit to be, undue brevity and obscurity in the column of remarks in the table. Whether he has seen only that portion of the article Portico in the Cyclopædia, I know not; neither do I know how he relishes the terms I have ventured to coin. Perhaps not at all: at least he has employed one term in a sense which I hold to be grossly solecistical and contrary to analogy, namely "*intercolumniations*," instead of "intercolumns": since the former term does not admit of a plural meaning, because it does not refer to the separate spaces or intervals between the columns, but merely the general arrangement, accordingly as the columns are put closer to, or further apart from each other. We therefore employ the first word very properly, when, with reference to that circumstance, we speak of the intercolumniation in a portico, &c., as being compact (*pycnostyle*), or straggling (*aræostyle*): but we should say "the centre *intercolumn* is wider than the rest;" or "there are seven *intercolumns*," and so on: for in such cases the other term is nonsense, and we might as well talk of a portico having eight or any other number of *columniations* instead of so many *columns*. Surely architects ought to know English well enough to feel the distinction at once; yet as a great many of them, it seems, do not, that must be my excuse for dwelling so long upon that little *lapsus linguæ*.

I remain, &c.,

L.

J. CROKER'S HINT TO THE SOCIETY OF BRITISH ARTISTS.

(In a Letter to the Editor.)

Sir—In noticing the Exhibitions at the Royal Academy, other publications besides your own have animadverted upon the very inadequate space there afforded to architectural drawings, in consequence of which, not only a great many are rejected every season, but of those admitted the majority are so hung up that they cannot possibly be examined, or even looked at all with any degree of comfort: accordingly those so placed are in danger of being altogether overlooked, let their merit be what it may. If the evil admits of no remedy nor mitigation—which, I for one, do not believe—complaint and remonstrance are of course useless. What surprises me, however, is to find that the Society of British Artists should not have had *nous* enough to take advantage of this circumstance, which they might easily enough convert to a trump card of their own. Surely it would be far better policy on their part, instead of entirely shutting up one of their rooms, as they have done for the two last seasons, to devote that room—which I should take to be quite as large as the one at the Academy—entirely to Architectural Drawings, and invite the profession (by public advertisement) to contribute designs. They might not perhaps be able to *fill* it—to get together such a *squeeze* of frames, as we invariably find in in the Architectural Room of the *Royalists*; yet that I conceive would be a very great recommendation rather than the contrary: and many—not the lowest of all in talent—would, it may be presumed, prefer the chance of a favourable situation in Suffolk-street, to the risk of being either turned out altogether from the building in Trafalgar-square, or else seeing their drawings hung up, where very few would be at the trouble of looking at them at all.

Nevertheless, I have been informed, upon most unquestionable authority, that the plan here suggested has been actually submitted to the council, by one of the members, and was thrown out almost *nem. con.* and without any *con*-sideration! Upon what grounds it is difficult to guess, for I believe no argument was attempted to be brought against it, except the most perverse and negative one, that it would do them—*i. e.* the painters—and their exhibition, no good whatever. Was there ever such grovelling, narrow-minded stupidity! Even granting that it would not render their exhibition more attractive, it could not possibly tend to make it less so. Those who did not care to look at such drawings would not be compelled to enter that particular room against their inclination. Neither would the addition of architectural drawings detract from their treasury: on the contrary, it might perhaps serve to draw a few more shillings into it. At all events the experiment would cost nothing—except, perhaps the printing one or two more pages in their catalogue,—and should it turn out quite a failure, they might then abandon the plan for the future. But until such proof be afforded, I will not believe that it would prove one: so far from it that I am of opinion the public generally would learn by degrees to take an interest in architectural designs and drawings by frequently seeing them: an opinion in which I am confirmed by a remark which Heinz makes in his notice of the architectural subjects at the Paris exhibition this year. After observing how desirable it is that the designs for all buildings of importance should be publicly exhibited beforehand: that considerable interest is thereby excited, and that critical remark and discussion are elicited, he continues thus: "It is idle to assert, by way of objection, that the public generally do not understand or relish architectural drawings: such argument will not hold water, when drawings of that kind are as beautifully executed as most of those in this exhibition. We had positive proof to the contrary, for we observed many even of the lower orders examining and apparently both understanding and gratified by them—even those which were sections. *Once afford the public the opportunity of seeing and becoming acquainted with architectural drawings, and they will very soon learn to understand them.*"

I make no further comment on this than to remark, that it is to be presumed the same might be the case here, unless, indeed it should be urged that English people are so very much more stupid than French people, that the latter country is no rule whatever for our own.—With respect to the British Artists and their enlightened Council, I leave them to chew the cud on what I have said. Neither I nor any one else can compel them to have common sense, if they are determined to have nothing to do with it. There is a saying which informs us that 'though one man can lead a horse to water, not ten men can make him drink;'—and so, I suppose, it must be with them: they will not swallow my prescription. Therefore, having sent you this epistle as a New Year's gift, I now take my leave, remaining,

Your's, with a Thousand Et-cæteras,

John Croker.

TABLES FOR RAILWAY CURVES.

Sir—Having heard much controversy between writers of scientific works, relative to the best mode of laying out segments of circles, whereby the prescribed limits of almost all lines of railway, render it, in the majority of cases, necessary to substitute curves of various radii; and I think several of your correspondents have not given the formula in a manner sufficiently comprehensive for general purposes. Having had frequent opportunities of determining curves upon several public works for some years, none yet appearstone so ably adapted, to all capacities, as the method you have set forth in the first number of your Journal for 1840, as to the accuracy of which I can testify, from having repeatedly put it into practice upon ground of no ordinary character.

I am, Sir,

Your obedient servant,

William Dodd.

Folkestone,
16th Dec., 1840.

Substitute for Tinning.—We have witnessed several interesting experiments calculated to test the success of an important discovery in the art of manufacturing cast-iron cooking vessels, by Messrs. T. and C. Clarke, the extensive iron-founders of Wolverhampton. English manufacturers of articles technically denominated "hollow ware," have for many years been sorely puzzled concerning an ingenious and beautiful method, practised in Germany, of lining iron culinary utensils with a smooth white enamel, resembling porcelain, which far surpasses, in point of cleanliness and durability, the English system of "tinning" the interior surface. Indeed, so desirable has this art been considered by our countrymen that, with their usual enterprise, considerable sums of money, and a most liberal expenditure of time and talent, have been for many years employed in seeking to discover the process. Until the present instance, however, every effort proved fruitless. Several of our manufacturers, it is true, have contrived to line the vessels with an enamel equal or superior in appearance to that of the foreign article: but this enamel cracked, chipped, and would not stand the fire; and the grand secret, which, of course, is the production of an enamel which shall so expand and contract with the metal as not to chip or crack, remained as much unknown as ever. Messrs. T. and C. Clarke, however, have at length most perfectly succeeded, and having, of course, secured a patent, are now manufacturing an article in every way superior to that of their Continental rivals. The manufacturers of British hollow ware have always surpassed those of Germany in the lightness and elegance of their castings, so that Messrs. Clarke are enabled to add this advantage to that of at least equal excellence of enamel. The German enamel is found to wear as long as the iron vessel itself, but we believe it will scarcely stand the severe test to which we have seen Messrs. Clarke's article subjected—viz., that of heating an enamelled saucepan to a white heat, and then plunging it suddenly into cold water, until cooled, without either the vessel cracking or the enamel being damaged or discoloured. Another experiment consisted in placing one of the vessels filled with water upon a large fire, and allowing it to remain until the water had completely boiled away, and for some minutes afterwards, without in the slightest degree injuring the vessel or its enamel. The great importance of the application of this discovery to our own manufactures is, that the hollow-ware manufactured in this country may be purchased at less than half the price of that imported from the Continent.—*Staffordshire Examiner.*

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

"On the Action of Steam as a Moving Power in the Cornish Single Pumping Engine." By Josiah Parkes, M. Inst. C. E.

(Continued from page 126, Vol. III.

Mr. Wickstead being called upon by the President, declined at present giving an opinion upon the theory before the meeting. He stated, that he was still trying experiments upon the engine at Old Ford—that the results up to the present time were in accordance with his anticipations—that, with small screenings of Newcastle coals, the duty of the engine amounted generally to 75 millions, and sometimes to as much as 81 or 82 millions. He thought that 7 lb. per square inch for friction and imperfect vacuum was too large an allowance for an engine of the size of that at Old Ford, as, when the speed was 10 or 11 strokes per minute, the power was equal to 200 horses, and, if an allowance of 6 or 7 lb. was made, it would be equal to 100 horses' extra power, which he felt certain could not be correct. At the same time, he believed that in very small engines the amount of friction, &c., might be correctly estimated at 6 or 7 lb. per square inch. He had also tried some experiments upon a Boulton and Watt low-pressure engine: by the introduction of Harvey and West's patent pump valves, the duty of the engine had been increased from about 28½ to 32½ millions. He was now trying experiments on clothing the cylinder, &c., and with steam in and out of the jacket: the result of all these experiments should be laid before the Institution as soon as they were completed.

Mr. Seaward considered the paper to be very valuable, as opening a new view of the action of steam, and inducing discussion and experiment; but he was not prepared to allow at once the percussive action, nor could he admit it to be the cause of the increased duty, as, if so, an augmentation of pressure in the boiler would give a corresponding increase of duty. Engines were worked at all pressures up to 60 lb., and even higher; but it was not perceived that the highest pressure gave the best results. He attributed the increase of duty to an improvement in the manner of using coal under the boilers; to the use of good non-conducting substances for clothing the cylinders, steam-pipes, &c., to prevent the radiation of heat; and to the general improvement in the construction of the valves and other parts of the engines, the proper dimensions for which were at present better defined. The expansive principle did not seem to have operated so well in the rotary as in the pumping engines. He had not hitherto credited the statements of engines working with a consumption of coal of 5 lb. per horse power per hour, nor of the great advantage of the use of steam at high pressures. Several Scotch boats had been worked with steam, at a pressure of 33 lb. on the inch, without any corresponding advantage. The increase of duty, then, he attributed to other reasons than the effects of percussion, as, independent of other considerations, the steam must always have possessed the same percussive force, which it must have exercised without producing the effects now attributed to it.

Mr. Wicksteed observed, that there were many reasons why the duty of the double expansive engines in Cornwall was not in proportion to that of the single pumping engines. The introduction of the former only dated from about the year 1834; but few had been made; there had not been the same amount of experience to guide the engineer in their construction; they were of small size, and consequently the amount of the friction was greater in proportion than in the large single pumping engines. Notwithstanding all these disadvantages, the duty had increased from 15 or 20 millions to 57 millions. It had been stated that the double expansive engines constructed by Hall and by Penn did not consume more than 5 lb. of coal per horse power per hour; while the ordinary low-pressure double engines required from 8 lb. to 10 lb. of coals. He would suggest to such members as possessed the power of verifying this fact to communicate their observations to the Institution.

Mr. Rendel would direct the attention of members to the main feature of Mr. Parkes's paper, which was the discovery of the action of a percussive force by the steam. The full investigation of this subject deeply interested the scientific world: and it was important that its merit should be clearly displayed. If any power could be gained from the percussive action, the more suddenly the steam could be admitted upon the piston, the more advantageous would be the result. It would be interesting to learn whether, in the changes in Cornish engines, from which such improved duty had resulted, any increased area had been given to the steam pipes and valves, and to what extent as compared with the old practice. If any change of this kind should be found to have taken place, it would be an argument in favour of the percussive principle.

Mr. Field expressed his sense of the obligations which the Institution owed to Mr. Parkes for having taken up this subject. It had been supposed by many persons that, independently of the economy arising from clothing the cylinder, jacket, and boilers, and the expansive action of the steam, some other cause might have assisted in producing the increase of effect in the Cornish engine. Doubtless, much had been done to economise heat and steam by the slow combustion of the fuel under the boilers, by diminishing radiation, and by expansive action. Nevertheless, the question to be solved was, Can these improvements account for the whole progressive advance in the duty from 40 or 50 to 90 millions? He trusted that Mr. Wicksteed would apply the indicator to ascertain [illegible] on the piston at every portion of the stroke.

Mr. Parkes remarked, that many persons [illegible] had [illegible] doubts of the sufficiency of the commonly-received theory of expansion to explain the excessive economy of the Cornish above the unexpansive engine. Some had recorded this opinion. Mr. Henwood found the steam's force in the Huel Towan engine unable to sustain the water-load alone. Messrs. [illegible] showed a similar deficiency of steam power in an engine at the United Mines; and Mr. G. H. Palmer was perfectly correct in his statement, that the absolute force of steam as commonly appreciated was inadequate to the performances assigned to it; but he was wrong in asserting that these effects had not been obtained, for they were indubitable.

As doubts had been expressed with regard to the accuracy and sufficient duration of the experiments selected as the basis of his analysis, he would state, that Mr. Henwood obtained the quantity of water consumed as steam, during a continuous observation of twenty-four hours, having previously measured the water discharged by a given number of strokes of the feed pumps, and then counting the entire number of strokes made to supply the boilers during the experiment. The pump was used periodically, and its whole contents injected into the boilers at each stroke, so that no material error could arise as to the quantity of water consumed as steam. With respect to the resistance overcome, Mr. Henwood several times measured the whole height of the lifts in the most careful manner, not comprehending the fact of the steam's force being unequal to sustain the load of water alone. Not content with this, he measured the water discharged by the pumps, and found a near correspondence with the calculated quantity.

Mr. Parkes would prefer a short experiment on the consumption of water as steam to a long one, as more likely to be accurate. He had rejected the eight months' experiment on the United Mines engine, as being unsuitable for the purpose of his investigation; for, during so long a period, the boilers must have been several times emptied and cleaned, stoppages must have occurred, condensation, leakage, and other circumstances must also have taken place, which unfitted that experiment for analysis. Long experiments were the best for the practical determination of the duty done by coal; but the action of steam in performing that duty was altogether a separate consideration. The consumption of water as steam for a single stroke of the engine, if it could be obtained, would be all-sufficient for investigating its action in the cylinder, as the weight raised by a Cornish engine must be the same at every stroke. If any error existed in the statement of the wated evaporated, it was more likely to be in excess than in deficiency; for it would be admitted that the conversion of 10½ lb. of water into steam, by 1 lb. of coal was not a common occurrence. Yet, granting this result to have been obtained, it appeared that there was not steam enough to overcome the resistance. Such was the result of the analysis of the Huel Towan and Fowey Consols engines, for which the evaporation was ascertained; and if less water had been converted into steam, the deficiency of power, compared with the effect, would necessarily have been still greater. Mr. Henwood's statement of the performance of the Huel Towan engine was confirmed by a previous trial of the same engine in 1828, conducted by a committee of twenty-one competent persons, when it appeared, after twenty-six hours' experiments, that 87,209,662 lb. had been raised one foot by a bushel of coals. Mr. Henwood's experiment gave 81,398,900 lb., so that in the analysis the lowest result was used.

It had been urged, that if any such force as percussion belonged to steam now, it always formed one of its properties. This was true; but it either may not have been well applied, or its effect not detected. The expenditure of power as derived from the quantity of water consumed as steam could not be determined so long as any condensation of steam took place in the cylinder; for whatever steam was there condensed had lost its power. The perfect clothing of the Cornish cylinders rendered the analysis of the action derived from a given quantity of water as steam nearly free from error.

Mr. Wicksteed had stated, that when he kept the steam out of the jacket of one of Boulton and Watt's engines, it required full steam throughout the stroke to overcome the load; whereas, with steam in the jacket, some expansion could be used. This would show a greater expenditure of power in one case to produce an equal effect. Such, however, could not be: an equal power operated in both cases; but in the one, a portion of it was annihilated, or had produced no useful effect.

Mr. Parkes considered it as demonstrated, that a force, independent of the steam's simple elastic force within the cylinder, did operate in the Cornish engines. The term *percussion* might be objected to when applied to an elastic fluid. Nevertheless, he conceived that the instantaneous action transmitted to the piston, on the sudden and free communication effected between the cylinder and boiler, must produce an effect analogous to the percussion of solids. He considered the proofs of such action adduced in his paper as irresistible.

He would ask how it could be accounted for that the steam was in a state of expansion during 19 out of 20 parts of the stroke in the Huel Towan engine, as shown by the indicator diagram, though it was freely admitted during one-fifth of the stroke, unless a velocity had been given to the piston by an initial force exceeding that of the steam's simple elastic force? How was it that, at the end of the stroke, the steam's elasticity was able to sustain so small a portion of the load in equilibrio, unless a momentum had been transferred to the mass by the impact on the piston, and aided the expanding steam to complete the stroke, which alone it was incompetent to perform?

larger degree of attenuation in which the steam was found on the completion of the stroke in one engine than in another, compared with the pressure of the resistance, and with the amount of expansion determined by the period of closing the valve, alone proved that the ordinary theory was inadequate to explain the action of steam in these engines.

He had for some time conjectured that a hidden and unsuspected cause influenced the performance of the Cornish engine; and if he had not been successful in discovering its nature, he considered the analysis as placing the fact beyond question, that the quantity of action resulting from the steam admitted into the cylinder was much below the force of the resistance opposed to it, and overcome.

June 23.—The President in the Chair.

John Frederick Bateman was balloted for and elected a member.

"*On the Stamping Engines in Cornwall.*" By John Samuel Enys, A. Inst. C. E.

The process of stamping or reducing the ores of tin in Cornwall, by means of iron stamp-heads, which crush the ore in falling upon it, was formerly effected in mills worked by water power. These have been, from economical and other reasons, for the most part superseded by the use of steam; and even with inferior engines, the result has been such as to enable the poorer portions of the lode (which were frequently left in the mine) to be now advantageously worked.

The work performed by the stamping engines was reported with that of the pumping engines, and showed the duty to be from 16 to 25 million lb. raised one foot high by one bushel of coal, as estimated from the actual weight of the stamp-heads. The engines appropriated for this purpose were generally old double-acting engines of inferior character, and not unfrequently in a bad state of repair. The use of expansive steam was tried with good effect upon them, and induced Mr. James Sims to build an engine calculated more fully to develop the advantages of this principle. He accordingly, in the year 1835, erected one at the Charlestown mines. It was a single-acting engine, communicating the movement direct to the cam shaft for lifting the stampers without the intervention of wheel-work. The first reported duty, in December, 1835, was 43 millions, which was two-fifths more than had previously been performed by stamping engines. Subsequently, Mr. Sims erected other engines of similar construction, and from them may be taken the reported duty in April, 1840:—

Charlestown Mines . . .	59,589,884 lb.
Carn Brae . . .	57,611,073
Wheal Ketley . . .	58,718,452

This increased duty induced other engineers to turn their attention to the subject, and they have constructed engines which equal these duties; the chief variation being the adoption of double action, which seems generally to be preferred.

This paper is accompanied by four drawings of the Carn Brae stamping engine, by Mr. Sims, junior, showing in great detail the construction of the engine and the stamping machinery.

"*On the Effects of the Worm on Kyanized Timber exposed to the action of Sea Water, and on the use of Greenheart Timber from Demerara, in the same situations.*" By J. B. Hartley, M. Inst. C.E.

There are probably few ports in England where the inconvenience resulting from the attacks of marine worms (*Teredo navalis*) on the timber of the dock gates and other works exposed to their action, is more severely felt than at Liverpool. The river Mersey has a vertical rise of tide of 27 feet at spring, and 13 feet at neap tides, and the stream being densely charged with silt, a considerable deposit takes place in the open basins, and to some extent in the docks. The latter are cleansed by means of a dredging machine, but the former are usually "scuttled," for which purpose sewers connected with the docks surround the basins, having several openings furnished with "clows," or paddles, so that the rush of water from the docks may be applied for clearing away the mud from any particular part of the basin. The security of these paddles is, therefore, of the greatest importance, as the failure of one of them might, by allowing a dock to be suddenly emptied, cause great damage to the shipping. These paddles have been usually constructed of English oak or elm, and being much exposed, they suffer from the attacks of the worms. Cast iron paddles have been tried; but in consequence of the rapidity of the corrosive action, they soon became leaky, and were abandoned. Kyanized oak timber has been tried on the back of these paddles, and found to be perforated by the worm in the same time as unprepared wood. Some oak planks, two inches and a half thick, Kyanized at the Company's yard, were used on the west entrance gates of the Clarence Half-tide Basin, and in 14 months were completely destroyed. Several similar instances of the non-efficiency of the Kyanized timber are given; and the author proceeds to designate the timber which resists best in such situations. He considers that teak is less liable to injury than English woods, and instances the inner gates of the Clarence dock, which have been built for 10 years, and at present are but slightly attacked.

The timber which he prefers for dock works is the Greenheart. It is imported from Demerara, in logs of 12 to 16 inches square by 25 to 40 feet long, and costs about seven shillings per cubic foot. Of its power to resist the attacks of worms, he gives many proofs: one of them may be cited. At the first construction of the Brunswick Half-tide basin, several elm clows were placed at the west entrance: these were destroyed by the worms in two years, and were replaced by others made of greenheart, the joints of the plank being tongued with deal, to render them completely water-tight. These clows have now been down about seven years, and, although the deal tongueing has been destroyed by the worms, the greenheart planking remains untouched and perfectly sound.

Many methods of protecting common timber have been tried, but the only successful ones adduced are—1st, the use of broad-headed metallic nails driven nearly close to each other into the heads and heels of the gates, but if driven an inch apart, the worm penetrates between them; and 2ndly, steeping the timber in a strong solution of sulphate of copper from the Parys copper mines in Anglesea. Some paddles made of English elm thus prepared had been in use upwards of three years, and, on an examination, were found to be very slightly injured; while the unprepared timber about them was quite destroyed.

The author observes, that the outer gates of the wet basins are most injured by the worm, from the sills being low down, and the change of water every tide assisting the growth of the worm. Those parts of the gates which are alternately wet and dry are more injured by the worm than the parts immersed always in the same depth of water. At the spot where a leak occurs from a bad joint, a defect in the caulking, or other cause, the worm commences its attack; so that the most incessant attention is required. Those basins into which the sewers of the town discharge themselves are comparatively free from the worm, from which it would appear that sulphuretted hydrogen gas acts in some measure as a protection against the attacks of the worm.

"*An account of the actual state of the Works at the Thames Tunnel, June 23, 1840.*" By M. I. Brunel, M. Inst. C. E.

In consequence of local opposition, the works have not advanced much since the month of March, 1840; but, as that has been overcome, and facilities granted by the city, the works will be speedily resumed, and the shaft on the north bank commenced.

The progress of the Tunnel in the last year has been, within one foot, equal to that made in the three preceding years. During those periods collectively, the extent of the Tunnel excavated was 250 ft. 6 in., and during the last year the excavation has been 249 ft. 6 in. This progress has been made in spite of the difficulties caused by the frequent depressions of the bed of the river. These have been so extensive, that in the course of 28 lineal feet of Tunnel, the quantity of ground thrown upon the bed of the river, to make up for the displacement, in the deepest part of the stream, has been *ten times* that of the excavation, although the space of the excavation itself is completely replaced by the brick structure. On one occasion the ground subsided, in the course of a few minutes, to the extent of 13 feet in depth over an area of 30 feet in diameter, without causing any increased influx of water to the works of the Tunnel. The results now recorded confirm Mr. Brunel in his opinion of the efficiency of his original plan, which is "to press equally against the ground all over the area of the face, whatever may be the nature of the ground through which the excavation is being carried." The sides and top are naturally protected; but the face depends wholly for support upon the poling boards and screws. The displacement of one board by the pressure of the ground might be attended with disastrous consequences: no deviation therefore from the safe plan should be permitted.

The paper is accompanied by a plan, showing the progress made at different periods. It is stated that a full and complete record of all the occurrences which have taken place during the progress has been kept, so as to supply information to enable others to avert many of the difficulties encountered by Mr. Brunel in this bold yet successful undertaking.

June 30.—Henry Robinson Palmer, V.P., in the Chair.

"*Description of an Instrument for describing the Profile of Roads.*" By Henry Chapman, G. Inst. C. E.

The object of the author in the invention of this instrument was to facilitate the mode of making a preliminary survey for railways by a machine of a simple construction, and composed of very few moving parts. It may be thus briefly described:—

A light frame with springs and upon four wheels carries the machinery, to which a rotary movement is communicated from one of the wheels, which is keyed fast upon its axle. A double-threaded screw and a series of wheels work give motion to a cylinder, upon which a length of paper is coiled; this cylinder revolves, and moves simultaneously in the direction of its axis. A pencil, which moves parallel to the axis of the cylinder, marks a line upon it, with a velocity varying according to the inclination of the road, and is so arranged, that when the machine is passing along a level, the motion of the pencil will equal that of the cylinder. In ascending inclined planes, it will be retarded, and in descending it will be accelerated. By these means a rising or falling line will be accurately drawn. This variation in the action of the pencil is accomplished by means of a friction-wheel working against a cone, the different diameters of which regulate and determine the speed. The position of the friction-wheel upon the cone is determined by the change of position of a pendulum vibrating within a case which is filled with a dense fluid, for the purpose of rendering its action more uniform.

The machine will trace a section of a road in lengths of five miles upon each sheet of paper, to a horizontal scale of 20 chains per mile, and to a vertical scale of 200 feet to an inch. That no inconvenience may be felt from the smallness of the scale, the instrument is furnished with scales with sliding verniers, from which memoranda can be made of the distance run, and of the variations above or below the datum line. These memoranda are made upon a strip of paper, which is fastened on a table, along which an index travels at a velocity corresponding with that of the paper on the cylinder; so that the strip of paper being afterwards laid upon the section, the points marked may be squared down without using the scales.

When the distance of five miles is passed over, a bell gives notice of the working machinery being disengaged: the section is removed, a fresh sheet of paper is introduced, and, as the pencil maintains its position, the section will be carried on continuously.

This communication is accompanied by three working drawings, showing, on a large scale, the machine in action, and all the component parts in great detail.

"*On the Efflux of Gaseous Fluids under pressure.*" By Charles Hood, F.R.A.S., &c.

The theoretical determination of the velocity with which gaseous fluids are discharged through tubes and apertures, has frequently been investigated by mathematicians: and as the question is one of importance in various branches of practical science, the author examines the several theorems which have been proposed for its elucidation, and compares them with the results obtained by experimental researches.

Dr. Papin, in 1686, appears to have first ascertained the law of efflux to be the same for both elastic and inelastic fluids, and the majority of the writers on the subject since his time have adopted as the fundamental *data* of their calculations, the hydrodynamic law of spouting fluids, by which the velocity of discharge is found to be proportional to the square root of the height of the superincumbent column of homogeneous fluid.

The author investigates particularly the methods of calculation proposed by Dr. Gregory, Mr. Davies Gilbert, Mr. Sylvester, Mr. Tredgold, and M. Montgolfier, and points out the differences which exist in their several methods. That of Mr. Sylvester is the only one which differs in any considerable degree from the simple law above stated; and his calculation is based upon the supposition that the respective columns of light and heavy air represent two unequal weights suspended by a cord, hanging over a pulley—by which mode of calculation, in the cases selected by the author for comparison, a result is obtained of only about one-third the amount given by the other methods. These calculations are compared with some experiments made by Sir John Guest at the Dowlais Iron Works, and also of Mr. Dufrenoy at the Clyde and at the Butterly Iron Works, recorded by him in his report to the Director-General of Mines in France. The results are tabulated; giving the pressure of the blast, the area of discharge, the velocity of the blast, the quantity of air ascertained by experiment, and the quantity shown by the several methods of calculation. From all these comparisons the author draws the conclusion that the method of calculation proposed by Montgolfier is the most accurate' as it is also the most simple. If the pressure be ascertained in inches of mercury, it is only necessary to find the column of air in feet equivalent to the pressure, and to multiply this number (as in the common case of gravitating bodies) by 64 feet, and then the square root of this product will give the velocity of discharge in feet per second. The equivalent height of the column of air in feet is found by multiplying the number of inches of mercury by 11,230 and dividing the product by 12, mercury being 11,230 times the weight of air. Allowing for a small loss by friction in the quantity found by experiment, the agreement between the theoretical and experimental quantities is extremely near. Rules are likewise given for applying these calculations to other gases of different specific gravities, which are also applicable to chimney draughts and to the expansion of air by heat.

End of Session 1840.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Tenth Meeting.—*September*, 1840.

(From the Athenæum.)

Section G.—Mechanical Science.

"*On certain Improvements on Locomotive and other Engine Boilers.*" By Mr. Hawthorn.

The object of this improvement is to prevent what is technically called "priming," to heat the steam on its passage to the cylinder, and to employ return tubes, as well as direct tubes, for heating the water. The advantages are said to be, that no water is carried with the steam into the cylinder, and a saving of fuel, through the arrangement of the tubes, from 30 to 40 per cent.

Mr. Scott Russell observed, that the plan of surcharging steam was much used in America. They work the steam expansively. Mr. Russell thought the *dome* shape in the fire-box inferior to the *flat staged* box, and was afraid that the steam, returning from the cylinder through the boiler, would merely abstract and not communicate heat.

"*On the Fan-blast as applied to Furnaces.*" By Mr. Fairbairn.

In explaining the methods to be pursued in adapting furnaces to the fan-blast, Mr. Fairbairn observed that it was well known that its application to the cupola for melting pig iron was attended with the most complete success, and the object of the present inquiry was to determine how far the same mode of blowing was applicable to furnaces on a large scale, for the purpose of smelting ores. Objections had been made to Mr. Fairbairn's plan, on account of the very low pressure at which the air is introduced into the furnace, and its insufficiency to force it through a mass of material such as is contained in the furnaces of this country, and which is from 30 to 40 feet in depth. To these objections Mr. Fairbairn replied, that the same had been urged against the introduction of the fan-blast to the cupola: that, in his opinion its efficiency was as the quantity discharged, and not the pressure, which regulated the passage of the air from the "twyres" to the top of the furnace. The fan-blast, when supplied with large apertures into the furnace, would, in his opinion, increase the process of calcination, effect a more equable temperature, and produce a superior quality of metal. It appeared, therefore, of importance that the experiment should be made, and Mr. Fairbairn offered to superintend its introduction, provided the proprietors of the numerous works in this country agreed with him in opinion, that the process would be advantageous both as regards expense, and the improved quality of the metal produced.

Mr. Smith thought the plan well worthy of being tried. It is not the *force* of the blast that is necessary, but the *quantity of air* introduced. In a cupola in which the blast is given by the fan, the iron is brought down in half the time that was necessary with the cylinder blast. Mr. Smith has no doubt of the success of the fan-blast in smelting furnaces, the heat being more uniform.

"*On Propelling Boats on Canals.*" By Mr. Smith.

Mr. Smith proposed that the steam power in the boat should drive two large wheels, of thirty feet diameter, which should bite the ground at the bottom of the canal. He exhibited a working model on this principle, which succeeded on the small scale; and he stated that he had tried it on a larger scale with the power of four men, and it had also succeeded. The wheels might be either on each side of the boat, as in the model, with a provision for a play of three or four feet, that they might accommodate themselves to inequalities at the bottom of the canal; or there might be one wheel in the centre of the boat, if constructed on the twin principle.

Mr. Scott Russell was not sanguine as to the success of this plan. The wheels must be made very heavy, in order to give the propelling power, and their weight would have an injurious effect at the bottom of the canal. A large steam boat would be necessary in order to get sufficient power, and if this large vessel were propelled at high velocities, the surge from the bows would be very great, and the stern would drag in the water.—Mr. Smith said, that he had confidence in the plan, notwithstanding the objections raised, and intended to try it on a large scale, and would report next year to the Association the results, whether favourable or otherwise.—Mr. Glynn remarked, that an attempt was made some years ago by Mr. Seaward, to propel boats on canals by means of wheels composed of two rims, with steps between them as a ladder, running on the bottom of the canal; but it was abandoned.

"*On a New Rain Gauge.*" By Mr. James Johnston, of Greenock.

Mr. Johnston described a new rain gauge, so constructed that the receiving funnel or orifice at which the rain enters, is always kept at right angles to the falling rain. By the action of the wind on a large vane, the whole gauge is turned round on a pivot, until the front of the gauge faces the quarter from whence the wind blows: and by the action of the wind on another vane attached to the receiving funnel, the mouth of the funnel is moved from a horizontal towards a perpendicular position according to the strength of the wind. The receiving funnel and vane attached to it are balanced with counterpoise weights, in such a manner that the wind, in moving them, has as much weight to remove from a perpendicular position, in proportion to their bulk, as it has when moving an ordinary sized drop of rain from the same position; by this means the mouth of the gauge is kept at right angles to the falling rain.

Mr. Milne gave an account of a High Pressure Filter for Domestic Purposes.—Mr. Thom stated, that from experience he found it was better to filter *downwards* than upwards.—Mr. Hawkins agreed with Mr. Thom, that filtration downwards is superior to filtration upwards; he preferred charcoal to sand for filtering, and preferred filtering without high pressure.

Mr. Dunn explained Ponton's Electro-Magnetic Telegraph, which instrument was exhibited in the model room.

Mr. Fairbairn described Hall's Patent Hadraulic Belt for Raising Water.

M. le Comte de Lille explained his method of laying down Wood Pavement, as exemplified at Whitehall.

The Rev. Dr. Paterson gave an account of an *Improved Life Boat*, which he called a Riddle Life Boat, because the bottom is like a riddle. The sides of the boat consist each of a hollow elliptical tube, to be made of sheet-iron, and from this it has all its buoyancy, which is unaffected by any influx of water. This boat, he said, was light, easily propelled, and drew only a foot or two of water; and besides being used for reaching vessels in distress, or carrying passengers to steam boats, it might be itself carried as a ship's boat—to be ready for use in danger, or difficult landing.

Mr. Williams stated, that this boat seemed to be original, and that he (Mr. Williams) would make a trial of it on a large scale.—Mr. Vignoles thought it might be usefully employed for pontoons.

"*On an Improved Rain Gauge.*" By Mr. Thom.

It consists of a cylinder two feet long, and seven inches diameter, sunk in [illegible] the mouth of it [illegible] receive the [illegible] water, the gauge [illegible] cylinder is put a float, with a scale or graduated rod attached to it, which will move up or down as the water rises or falls in the cylinder. There is a thin brass bar fixed within the funnel, about half an inch under its mouth, with an aperture in the middle just large enough to allow the scale to move easily through it. The upper side of this cross bar is brought to a fine edge, so as to cut but not obstruct the drops which may alight on it. There is an aperture also in the bottom of the funnel, through which the water must pass into the cylinder, and through which also the scale must move; but this aperture requires to be made no larger than just to permit the scale to move through it freely. When the gauge is firmly fixed, and the float and funnel in their places, water is to be poured in till the zero of the scale is level with the upper edge of the aperture.

Mr. Thom gave an account of the water filters used at Greenock and Paisley. A species of trap rock or amygdaloid, common in the neighbourhood, is broken to the size of small peas, and mixed with fine sharp sand. The water is filtered by passing directly downwards through the media, which media are in their turn cleansed by passing the water through them upwards. The filter does best at two feet of pressure and under.

"*Description of a Revolving Balance.*" By Mr. Lothian.

The opposing arms of this balance are curved, being formed of two spirals, the one situated vertically over the other, and both bending round a common centre of movement, which is placed in the pole of the upper curve. The spirals diverge from each other near their origin, but approach and merge together at their extremes, and thus form one continuous curve, which is grooved on its circumference. The cords or chains which suspend the receiving scale and counterpoise act against each other in this groove—the weight of the scale, when hanging from a lengthened radiant of the upper spiral, being in equilibrio with the greater weight of the counterpoise when hanging from a shorter radiant of the lower one. When this state of rest is disturbed by loading the scale, the balance moves round, and, in the progress of its revolution, the opposite eccentricities of the spirals combine in changing the ratio of the leverage, and thus originate a self-adjusting power, by which the loads of both cords are mutually moved into equilibrium. The receiving scale thus commences with greater, and ends with less mechanical power than the counterpoise—a circumstance which is in harmony with the purpose of employing an unchanging weight to measure others both less and greater than itself; while the principle is one which concentrates the power and abridges the size of the machine. In order, however, that the total amount of adjusting power thus generally obtained may be equally drawn upon and advantageously distributed throughout the movement of the balance, a definite relation is established between the weight of the counterpoise and the rates at which the accumulating weight of the scale and the leverage of the lower spiral increase. The leverage of the upper spiral, being derived from these ascertained conditions, is made to preserve a rate of decrease which accords with the previously regulated increase in the leverage of the lower curve; while both spirals have their precise form determined by the additional consideration of the direction in which the cords exert their power on the circumference of the balance. In their calculated formation, the two spirals are thus dependent on and related to each other, while together they are component parts of one continuous curve, in which the mutual and combined changes of leverage are made to follow an equable, as well as a general progressive gradation; by which means, the balance is moved through equal angles by equal weights. In machines intended for weights of considerable amount, the balance is made to revolve about an axis, which is itself supported, a little above its centre, on knife-edge rests, so as to combine the movement of the revolving balance with the libration of the common one—the coincidence of a pointer from the axis with the ordinary pointer of the machine showing when the indication is practically unaffected by friction. In machines for weights of still greater magnitude, the articles to be weighed are made to act, in part, as their own counterpoise, by adopting differential curves to diminish the descending power of the scale; by which a comparatively small counterpoise is made to adjust the unsupported difference of weights greatly exceeding itself.

"*On the Combustion of Coal and the prevention of the generation of Smoke in Furnaces.*" By Mr. Williams.

Mr. Williams observed, that in treating on steam and the steam-engine, the subject divides itself into the following heads:—1st, The management of *fuel* in the generation of *heat*; 2nd, The management of *heat* in the generation of *steam*; 3rd, The management of *steam* in the generation of *fuel*. The first belongs to the *furnace*; the second to the *boiler*; and the third to the *engine*. The first, although exclusively in the department of chemistry, is to be considered in the Mechanical Section, for the purpose of showing its connexion with the practical combustion of fuel in the furnace. The main constituents of coal are carbon and bitumen: the former is convertible, in the *solid* state, to the purpose of generating heat: the latter, in the *gaseous* state alone, and to this latter is referable all that assumes the character of *flame*. The greater part of the practicable economy in the use of coal being connected with the combustion of the gases, this division of the subject is peculiarly important. We all know that combustible bodies cannot burn without air: the actual part, however, which air has to act is little inquired into beyond the laboratory: yet on this part depends the whole of effective combustion. Having explained the nature of combustion, Mr. Williams went on to show, that all depended on bringing the combustible and the air into contact in the proper quantities, of the proper quality, and at the proper time—the proper place, and the proper temperature. The conditions requiring attention were, 1st. The quantity; 2nd, The quality of the air admitted; 3rd, The effecting their incorporation or diffusion; 4th, The time required for the diffusion; and, 5th, The place in the furnace where this should take place. Mr. Williams exhibited several diagrams, representing the several processes connected with the combustion of a single atom of coal-gas or carburetted hydrogen, and also of bodies or masses of such gas. The essential difference between the ordinary combustion of this gas in combination with atmospheric air, and that resorted to by Mr. Gurney in combination with pure oxygen, in what is called the Bude light, was then explained. By these diagrams, it was shown, 1st, What was the precise quantity of air which the combustion of gas demanded; 2nd, The degree or kind of mixture which combustion required; and, 3rd, That the unavoidable want of time in the furnace to effect this degree of diffusion was the main impediment to perfect combustion, and the cause of the generation of smoke. From the consideration of these details, the inference followed, that smoke once generated in the furnace cannot be burned,—that, in fact, smoke thus once generated became a new fuel, demanding all the conditions of other fuels. Mr. Williams dwelt much on the chemical error of supposing that smoke or gas can be consumed by bringing it into contact or connexion with a mass of incandescent fuel on the bars of a furnace: that, in fact, this imaginary point of incandescence, or the contact with any combustible body at the temperature of incandescence, was peculiarly to be avoided, instead of being, as hitherto, sought for; and hence the failure of all those efforts to prevent or consume smoke. The great evil, then, of the present furnaces was their construction, which did not admit the necessary extent of time (or its equivalent), time being essential to effect the perfect diffusion of mixture of the gas, of which every chemist knew the importance, and on which the experiments of Prof. Graham were so conclusive. Mr. Williams then proceeded to show, that unless some compensating power or means be obtained, and practically and economically applied, we can never arrive at full combustion, or prevent the formation of smoke. This compensating power was shown to be obtainable by means of surface, and was well exemplified in the blow-pipe: the remedy then, for the want of time in the furnaces, may be met, by introducing the air in the most effective situation, by means of numerous small jets. Mr. Williams submitted the primary law to be this; viz., that no larger portions of air, that is, no greater number of atoms of air, should be introduced into any one locality, than can be absorbed and chemically combined with the atoms of the gas with which they respectively come into contact. Again, that the effecting, by means of this extended surface, this necessary diffusion was the main condition which required attention, and not that of temperature. Mr. Williams then exhibited the diagram of a boiler to be constructed on the above principles, and stated that he had an experimental boiler at work, which fully proved the accuracy of the principle.

Sir John Robison stated, that the Committee of Recommendations had suggested the appointment of a Committee to make a further investigation, and report to the Association at their next meeting.—Mr. Vignoles observed, that the gradual increase of the aperture for the blast of cupolas for second meltings of metal, the areas of which were now at least fifty times larger than formerly, proved the necessity of admitting large quantities of oxygen in combustion, which could only be obtained in its combination with the nitrogen, the other component part of atmospheric air.

"*On the Temperature of the Earth in the deep Mines in the neighbourhood of Manchester.*" By Mr. Eaton Hodgkinson.

Mr. Hodgkinson having, some years ago, received from Prof. Phillips four thermometers belonging to the Association, got, through the kindness of the proprietors of the following pits, and other parties connected with them, experiments made upon the temperature of the earth in each of them:—The salt-rock pit, 112 yards deep, belonging to the Marston Salt Company, near Northwich, Cheshire; the Haydock Colliery, 201 yards deep, near to Warrington; the Broad Oak Coal-mine, 329 yards deep, near to Oldham. In the latter pit, a thermometer placed in a hole three feet deep, bored in "metal," and closed at the aperture, was examined weekly by Mr. Swain for twelve months, the temperature varying from 57° to 58½° Fahr.—it being lowest from the beginning of February to the middle of May, and highest in September and October to the middle of November. The experiments above mentioned were made in 1837 and 1838, and the results mentioned at the Birmingham meeting; but the Broad Oak pit having been increased in depth since that time, a thermometer was inserted in it, in a hole bored in metal, as before. It was in a place 408 yards deep, and indicated a temperature of 61°, remaining nearly constant for twelve months. Mr. Fitzgerald being recently engaged in sinking a deep coal-pit at Pendleton, two miles from Manchester, Mr. Hodgkinson conceived this to be a favourable opportunity for getting additional information on the subject of subterranean temperature, and, on his application to the proprietor, the engineer (Mr. Ray) readily made for him, during the sinking of the pit, and afterwards in the workings, the experiments of which the results are below. At 418 yards from the surface, the temperature, in a hole from three to four feet deep, bored in dry rock, was 66°; at 450 yards deep it was 67°; and at 480 yards it was 69°. In the workings at 461 and 471 yards deep, it was in both cases 65°. The mean temperature of the air at Manchester, according to Dr. Dalton's experiments, is 48° Fahr.; and, as the pits above mentioned are not very far from Manchester, the mean temperature of the earth at the surface of each of them may be considered as 48°. With that supposition, the distance sunk for each degree of Fahrenheit would be as below:—

In the rock pit	32 yards.		
Haydock coal pit	20 „		
Broad Oak pit	33·7, 31·4	32·5 „	= mean.
Pendleton pit (shaft)	23·2, 23·7, 22·8	23·2 „	= mean.
Ditto (in workings)	27·1, 27·7	27·4 „	= mean.

The mean from the whole being 27 yards for each degree of temperature.

The President remarked, that Mr. Hodgkinson's results gave the rate of increase of temperature greater near the surface, and then decreasing, which did not agree with the results of other observers: this, he conceived, arose from nearly the same cause as that already remarked upon when Mr. Fox's report was under consideration. Mr. Hodgkinson commenced to reckon his descents or depths, not from the surface, but from the plane of invariable temperature, which in these latitudes was not far from 60 feet.—Prof. Forbes illustrated simply by a diagram how this caused the rate of increase at first to be too high, and then to diminish. He then alluded to the frozen soil of Siberia, gave a description of it, and said, that it had been sunk through to a depth of 382 feet without being penetrated—that is, without reaching a temperature of 32°, although the temperature of the surface was not below 18°. In this case, the rate of increase was rapid.

"*On the Temperature and Conducting Power of different Strata.*" Prof. Forbes's Report.

In this report, he wished to give the results of the observations made at Edinburgh during the year 1839, upon thermometers sunk at depths of 3, 6, 12, and 24 French feet into trap rock, pure loose sand, and sandstone. The details for the years 1837 and 1838 were already laid before the British Association at Birmingham. In order to render the report of the results for 1839 intelligible, Prof. Forbes went over nearly the same explanatory matter as that which is already published in the report referred to. He then exhibited the curves derived from the three years' observations, remarked upon their wonderful agreement, and gave, in a tabular form, the results for the three years, which were as follows:

Values of A (A being the constant in the formula given in the report referred to).

	In trap.	In sand.	In sandstone.
For 1837	1·164	1·176	1·076
1838	1·173	1·217	1·114
1839	1·086	1·182	1·049

Values of B (the other constant).

	In trap.	In sand.	In sandstone.
For 1837	·0545	·0440	·0316
1838	·0641	·0517	·0345
1839	·0516	·0498	·0305

Variation reduced to 0·01° Centigrade.

	In trap.	In sand.	In sandstone.
For 1837	58.1 feet	72·2 feet	27·3 feet.
1838	49·3	61·8	91
1839	59·2	63·5	100

Velocity of propagation for one foot of depth.

	In trap.	In sand.	In sandstone.
For 1837	7·5 days	7·1 days	4·9
1838	6·8	6·8	3·6
1839	7·8	7·2	4·6

"*Observations on the Tides in the Harbour of Glasgow, and the velocity of the Tidal Wave, in the estuary of the river Clyde, between Glasgow and Port Glasgow.*" By William Bald.

Mr. Bald stated that he had been for a considerable time past engaged in making observations on the rise and fall of the tides in the harbour of Glasgow. The first series of observations was commenced on the 26th of April 1839, and extended to the 1st of October 1839, and contain 158 observations of the rise and fall of the tides. The first portion of these observations were only made during the day, and did not extend to the night tides. These 158 observations assigned the mean rise and fall of tide in the harbour of Glasgow, to be 6 ft. 7 in. 20d.* The number of tide observations made from the 1st of October 1839 to the 27th August, amounts to more than 1,200. These also had been tabulated and divided into months, but such of the tides as have been much disturbed by floods Mr. Bald had rejected. By reference to the table exhibited for October 1839, the first line stated from the 1st of October to the 7th of October, number of tides 13; mean rise and fall of these 13 tides was stated to be 6 feet 5 inches; the mean low water of these 13 tides below top of South Quay wall in the harbour of Glasgow, was 15 ft. 8½ in., the mean high water below top of South Quay wall, 9 ft. 3½ in.; and the mean half-tide level below top of South Quay wall, 12 ft. 6 in. The table showed the number of tides for new moon, first quarter, full moon, and last quarter; the total number of tides for each month, the mean rise and fall of tide per month, the mean low water below top of South Quay wall, mean high water below top of South Quay wall, and mean half-tide level below top of South Quay wall per month. The mean rise and fall of these 1213 tides assigns an average of 6 ft. 8 in. 98d.; and the first series of 158 tides assign a mean rise and fall of 6 ft. 7 in. 20d. It also appeared from other tables and observations, that the tidal wave runs from Port Glasgow to Bowling, at a rate or velocity of 14·56 miles per hour. from Bowling Bay to Clyde Bank, at a rate of only 6·82 miles per hour; but from Clyde Bank to Glasgow Harbour at a rate of 10·85 miles per hour. The diminished velocity between Bowling Bay and Clyde Bank arises from the channel of the river being more crooked in that part than any other portion, thereby showing the great necessity of straightening and improving it.

* Smeaton, in his report on the River Clyde, dated the 3rd September 1755, states the neap tides as only being sensible at Glasgow Bridge.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Monday, Dec. 7.

The first meeting of the Session was held this evening, the President Earl De Grey, in the chair. His Lordship in taking a short view of the arrangements proposed for the opening session, congratulated the members upon the prospects before them, and upon the increasing prosperity of the Association.

A paper was read upon some of the characteristics of the "Gothique flamboyant," from the pen of Professor Willis, honorary member. The peculiarity to which the Professor chiefly referred, was the complicated manner in which the mouldings and members are made to cross and interpenetrate in the French Gothic. The system is not unknown in the English perpendicular style, but with us it is confined to such cases as arise simply from the juxtaposition of the component parts of the architecture, whereas in the Gothique flamboyant, new members are unsparingly laid one over another with the express object of producing the most intricate combinations. Some curious examples were exhibited from the Cathedral of Nevers, and other continental buildings.

Dec. 21.—Charles Barry, Esq., in the Chair.

M. Duban, of Paris, and Signor Raffaele Politi, of Girgenti, were elected honorary and corresponding members.—The former of these gentlemen is the architect of the New Ecole des Beaux Arts, at Paris, and is greatly distinguished by his knowledge of the French national architecture of the sixteenth century.—Signor Politi is the author of a work on the Antiquities of Agrigentum, and is well known and highly respected by all English artists who have visited the shores of Sicily in the prosecution of their studies.

A paper was read on Gothic Vaulting, by Mr. Ferrey, Fellow, exemplified by a description of St. Katharine's Chapel, at Abbotsbury, in Dorsetshire, a building of the reign of Edward IV., very peculiar both in its design and construction, and especially remarkable for its great solidity, which seems to have been dictated by the elevated situation of the building, and its exposure to violent sea storms. The roof, which is a wagon headed vault is of solid masonry, every part affording a like degree of strength, contrary to the ordinary mode of Gothic vaulting, where the ribs alone yield support, the panels being rebated or borne on the back of them. Upon this vaulting is laid a body of rubble, shaped to the angle of the external roof, and upon the rubble the outer covering, consisting of regular masonry, each stone having a level bed, and being therefore secured in a manner totally different from stone tiling. The details of this roof, and of several other Gothic vaults with which Mr. Ferrey compared or contrasted it, taking occasion to introduce many general remarks, were exhibited in numerous drawings, and an attempt to follow the subject, independently of these illustrations, would be an injustice to an excellent practical paper.

ARCHITECTURAL SOCIETY.

Ordinary Meeting: 17th Nov., 1840.—Michael Meredith, Esq., in the Chair.

The Chairman expressed his regret at being obliged to inform the meeting that Mr. Phillips, who was to have read a paper this evening, had very unexpectedly been called from London, and was, in consequence, unable to fulfil his engagement with the Society, and having apologized for Mr. Philip's absence, stated that he had, by special request, brought up, for the inspection of the meeting, drawings to the same scale, from actual measurement, of three churches built by Sir Christopher Wren, viz., St. Bennett Finck, Threadneedle Street; St. Bartholomew, Bartholomew Lane, Bank; and St. James's, Garlick Hill, Doctor's Commons. Also two sketches, being designs for the new painted window, Bishopsgate Church.

Mr. Meredith made some observations on the system of competition, which were well worthy of consideration, and in so doing introduced to the attention of the meeting the designs for the new painted window in Bishopsgate Church, and he finished this portion of his subject by some interesting remarks on the design and effect of painted windows in general.

Mr. Meredith also made some observations on the great talent exhibited by Sir Christopher Wren in the designs of the churches introduced this evening, and offered a summary comparison between the churches erected by Sir Christopher Wren in general, and those erected by other architects in and about London.

Monthly Meeting: 1st. Dec., 1840.—William Tite, Esq. President in the Chair.

Mr. A. W. Hakewill read a most interesting paper, being extracts from the life of Mons. Percier, which he enlarged upon with some very ably penned remarks of his own, founded on observations made while in pursuit of his studies in Rome and Italy, and having reference to the classic taste displayed in the buildings of that country, and also to the fitness of the design for the purposes intended.

MEETINGS OF SOCIETIES IN JANUARY.

At Eight o'clock in the Evening.

Institution of Civil Engineers, Tuesday	12	19
Royal Institute of British Architects, Monday	11	25
Architectural Society, Tuesday	12	26

TEMPLE CHURCH.

(From the Times.)

Within the present century a marked, and it may be called a classical taste has in general been shown whenever repairs or additions have been required to the ancient architectural remains, the legacies of our Anglo-Saxon ancestors, whether ecclesiastical or civil. The real or affected distaste for what was contemptuously called Gothic architecture, which may be dated from the time of the second Charles, continued to increase till the accession of George III. The passion for the antique in the reign of the former would appear even to have blinded Sir Christopher Wren to the absurdity of attempting to improve the wild and mysterious architecture of Saracen or Celtic origin, by uniting it to the classic regularity of the Greek or Roman school. The failure of the attempt appears in the towers of Westminster Abbey, and in the altar screens of many of the cathedrals erected from his designs. It is but in the present century that the genius of Wyattville restored the royal seat of Windsor to that character of castellated and palacial magnificence which the fopperies of Charles had obscured. How many sacred edifices might be pointed out, the "dim religious light" of whose venerable walls seem as if they breathed devotion, and which, in the most careless, are calculated to call the mind from the thoughts of the fleeting present to the eternal future, were they not desecrated by the "beautifications" which on all sides they are informed have taken place, during the presidency, may be, of the worshipful churchwardens Ebenezer Smith, or Timothy White, the testimonials of whose patriotic parochial monstrosities are handed down to posterity emblazoned in golden letters on gigantic tablets, and the fruits of whose exertions appear in the loads of whitewash and paint which has destroyed the severity and altered the character of the ancient structure. The time-worn banner of the founder in many may still be seen drooping over the poetical encomiums passed on the machinations of these utilitarian worthies, as if it "lamented the weakness of these later times,"

These heresies of taste are, however, giving way before a better understanding of the beautiful, as is exemplified in the repairs which have lately taken place in the cathedrals of Norwich, Rochester, and Peterborough, the Abbey of St. Alban's, and the borough church of St. Saviour's, from which last the western part of the edifice must, however, be excepted.

That affectation of puritanical simplicity in the fitting up of our churches, which to many of them has given rather the appearance of a hall devoted to the meetings of a civic council than a temple of divine worship, is also fast disappearing: a better taste has arisen, which is shown in devoting the labours of art and the efforts of genius in decorating the edifice itself, making it worthy the purpose for which it is designed, rather than in extolling the parentage of living monied humanity, or applying it to the luxurious accommodation of those who feel more disposed to hear the Gospel of truth when they find, in the house of their creator, the luxurious accommodations of their own.

The church called the Temple, although considerable sums were, some few years since, expended on it, has, on inspection, been found in such a state of decay, that its actual existence, for any lengthened period of time, was more than doubtful: in consequence of this, the Societies of the Inner and Middle Temple have generously determined that it shall be restored to its pristine state and beauty; they have justly considered themselves as guardians of one of the most ancient and beautiful ecclesiastical monuments of our country, and one of the very few which the fatal fire of 1666 spared in the metropolis. In the repairs of this church, it has been determined entirely to adhere to the ancient model, to do away with all the meretricious additions and miscalled embellishments with which its walls have been encumbered, to clear the interior of the wooden pens which have been planted in it, and to offer it to the antiquarian and the public, when completed, as the most perfect metropolitan specimen of the olden time.

The repairs of this church, when finished, will make it so perfect a specimen of ecclesiastical architectural beauty and chaste magnificence, as can hardly be rivalled in the kingdom. Many of the cathedrals may, in portions of their elevations, and in the ornamental garniture, if it may so be called, of their interiors, be as perfect: but as they have, with few exceptions, been erected in different ages, their architecture does not symmetrically harmonize together. There are few of them in which the Saxon, the Norman, the Saracen, the Gothic, or the Greek or Roman style is not blended in different portions of the edifice, and, the eye becoming confused by diversity, the effect which a symmetrical whole has on the imagination is lost. It may even be a matter of doubt whether the introduction of modern monumental sculptures, however great may be their merit as works of art, when not in alliance with the character of the locations in which they are placed, does not materially deduct from the effects of both.

The repairs and alterations which are taking place in this church consist in removing all the pews which occupied and encumbered the centre of the building; they will be replaced by a series of stalls carved in oak coeval with the character of the edifice, which will be placed north and south in the manner of those in a cathedral, sufficient space is left between them and the walls to allow a passage; in the centre will be convenient moveable benches. By this means the magnificent grouped columns will be visible from their bases to their capitals: the modern screen erected in the time of Charles II., which separated the western from the eastern portion of the edifice, is removed, as is also the organ, which was placed upon and completed the partition; it will be fixed on a building which has been erected on the western side of the structure, which communicates with the interior of the church by two of the lateral windows. By this arrangement a great advantage is gained, the whole extent of the church, with its lofty columns, intersecting arches, and vaulted roof, strikes the eye on entering the Roman portico of the western entrance. It was incontestibly proved, in removing the barbarous whitewash from the vaultings, that they had originally been painted in the most splendid tints; there was not enough left to show the particular design, but it has been determined that they should be restored, which has been done with the elegance and richness which characterized ornaments of the class. The vividness of the colours and the delicacy displayed on this mosaic fresco, relieved by the dark sculptured divisions of the vault, has rarely been surpassed. On removing the floor to examine the bases of the columns, it was found that its original level was considerably below its late one; it is to be so replaced that they will have their just proportions: the pavement will be formed, not partly of wood and marble as before, but painted tiles and tesselated pavement, in the manner of those of the sanctuary of Winchester. The three windows at the eastern end of the church and others at the south side, will be filled with stained or painted glass in the ancient manner, composed of small pieces, the figures and ornaments of which will harmonize with the age of the edifice; they are in the hands of Mr. Willement, who designed the ceiling; he has preserved in them that minuteness of execution, that delicacy of detail, and that brilliancy of colour united with chasteness of design, which so well assimilates with the architecture of a Gothic edifice. The arms of the Society will be emblazoned in it, those of the Inner Temple, which consist of a horse striking the earth with his hoof, or "a Pegasus luna on a field argent."

The monuments, excepting those of the recumbent knights in the round church, have been removed, and it is proposed to erect a cloister adjoining, and communicating with the edifice, to receive them. This will be a great improvement: the beautiful simplicity which the building in its leading lines presents, a heterogeneous series of monuments, tablets, and inscriptions must necessarily destroy; the space between the windows is too small, and never was intended for them; besides which, it will allow of these parts having a decoration of ornamental painting, similar to that of the ceiling, this being necessary to give due and complete effect to the latter. Immediately under the windows is a marble cornice, which, when restored, will seem to belt round the building and justly lead the eye, by its unbroken line, to give full value to its extent. All the smaller columns which are attached to the internal ones that support the roof, and those on the side walls which receive the ribs of the arches, are found, the smaller to be Purbeck marble, and the larger of Caen stone; whitewash, neglect, and age had effectually concealed their beauty; the splendid polish of the former, which rivals a mirror in brightness, will be restored, and their hue of ebony will stand in effective contrast with the cream-coloured hue of the latter. The caps of those in the round church are beautifully carved, according to the fashion of the age in which they were constructed. The outline of all is uniform, and the detail of each is varied; by this a simplicity and singleness of effect is produced in the whole, and the minutest examination presents a never-ending variety, by which the first impression is extended and maintained. The whole of these architectural restorations are being executed under the direction of Mr. Savage, of Essex Street. When completed, this ancient edifice will become an additional ornament to the metropolis—a perfect and unrivalled specimen of the olden time. But the restoration of this beautiful church is not the only good which the liberality of the Societies of the Temple will have effected; they have been the means of proving what may and can be done by the artists and artizans of England, when taste directs and liberality remunerates. Such an example, set in such an edifice, will, in all probability, have a powerful effect in the progress of church decoration in all its departments.

LAND SURVEYING—THE SCALING INSTRUMENT.

Sir—Though having had something to do with the improvement of the new scaling instrument, now used in the Tithe Commission Office, yet I do not feel called on *seriously* to contradict the assertions of "Surveyor," which appeared in your last month's publication. Nor would I presume to obtrude the following observations on your pages, if the remarks that called them forth had not a tendency to contravene the great principle upon which your very useful work is professedly based. It appeared that your valuable publication was to be made the great reservoir wherein to deposit the beneficent contributions that freely emanate from the generous and communicative head of genius, and from which source, those valuable contributions may be made liberally to circulate for the noble and philanthropic purpose of giving increased facility to the *practical efforts* of such persons as may not be so largely endowed with the inventive faculty.

Some few however there are to be found so exceedingly contumacious—so irresistably wedded to old prejudices—and so very vain of their fancied perfections in their several professions, that, like the barbarian Chinese, they reject with affected scorn every proposed improvement, the adoption of which would involve them in the painful and humiliating admission, that there existed such a *monster* as a *superior!*

With "Surveyor," continuous labour is professedly preferable to ease and dispatch. If labour be the consequence of a "curse," every inventive ability given and exercised, to remove or lessen that physical incubus, evinces a disposition somewhere to lighten the anathema: but if the stand still or retrograde movement stupidly advocated by "Surveyor," be acted on, we must be content (though human necessities daily increase) painfully to endure the miserable infliction: we must be satisfied to spend months at the drudgery of trigonometrical, or astronomical, or other calculations *in the old way*, rather than avail ourselves of the "ready reckoner" or the log books prepared by a Napier or a Newton—lest the month's labour should be diminished to *so many* days—and that we might not *dishonourably* substitute the easy effort of the boy, for the overstrained and painful exertions of the man!!

But we tell "Surveyor" that there is not the slightest chance that his intimation will have any effect. And likewise, that the advocates of all petty interests and monopolies, however they may frown and storm in their pigmy habiliments, must bow the neck to the overwhelming force of successful improvement and reform.

From the self-confident tone of "Surveyor," one would be led to suppose that he would willingly submit to a fair trial between his old method and the application of the instrument; if it were only for the purpose of convincing other persons who have given it a trial, that he was sincere in his rejection of it; and that he had no sinister motive for giving public expression to the act of "laying it on the shelf."

I now confidently assert that the same quantity of average work may be done twice with the instrument, for once that it can be done by "Surveyor's" method, and with a much greater degree of accuracy, and defy him to the practical disproof upon any fair conditions he may propose.

One can scarcely suppress the full ebulition of his risible faculties on reading the latter part of his letter, at his puerile attempt to touch the high reputation of a notable and eminent engineer, by his ("Surveyor's") *generous* offer of a lesson at the chain. From such a sample we may expect that the next unsolicited proposal of this astonishing preceptor will be, to instruct some of the first literary characters of the day in the letters of the alphabet. On this point, however, it is apparent that the very limited extent of his own acquirements has rendered him incapable of recognizing or appreciating the full extent and variety of, individual acquisition.

With these few remarks I beg to conclude, hoping that if "Surveyor" should again have any desire for entering your columns, that he will do so with a single eye to the main object of your Journal, and not under the mere influence of selfish or vindictive passions.

I have the honour to remain, Sir,

Your very obedient servant,

B. T. C. O.

December 24, 1840.

REVIEWS.

(*Continued from page* 16.)

A Practical Inquiry into the Laws of Excavation and Embankment upon Railways, &c. By a Resident Assistant Engineer. London: Saunders and Otley, 1840.

(Second Notice.)

The remaining part of this work which we have announced our intention of noticing, is devoted to the investigation of the barrowing system, in which the author proposes to give the result of his inquiry into the subordinate system of removing earth by means of wheel barrows and human labour. We regret that even the small share of praise we felt justified in bestowing on the first part of the treatise cannot be extended to the part now before us.

And in order that our readers may the better judge in what degree the author is warranted in the strong contrast which he draws between his own labours in this field of inquiry, and those of former writers, we shall present them with an extract from his works, rather out of its true position, namely, the concluding paragraph, in which he glances with some contempt at the efforts of his predecessors, and turns with infinite complacency to the superiority, in all respects, of the process which he has himself employed.

> It will also be seen, that the principles upon which former authors attempted to develope the general laws of excavation and embankment, were evidently adopted, without any reference to the practical working of the system: and, that the mode of making their observations, (whenever they were made), was much too isolated, for the purpose of affording an expanded and comprehensive view of the various agencies—collateral and direct—which are continually acting, one upon the other, and by which the ultimate results are collectively influenced. The error into which they have fallen, seems to have consisted in assuming, as their constants, quantities in the abstract; or in observing in detail, instead of the aggregate; and adopting the results of these separate observations, as if entirely independent one of the other: and therefore it is not to be wondered at, that many matters, essential to the thorough sifting of the subject, were altogether excluded: and that the arguments founded upon these self-begotten phenomena, led them to a belief. in the inverse ratio to probability, if not of possibility itself. Thus, the antecedents being widely unconnected, and, from their number, subject to frequent error; the consequents derived from their combination, turned out utterly fallacious. The method we have pursued is exactly the reverse: our constants depend upon observations, made upon the combined effects, produced by the various agencies in the aggregate: and, by an analysis of these we have descended, step by step, to the details; and not advanced, from the minutiæ of detail to abstract generalities, which have no foundation in truth

We shall reserve till the end of our review the observations we have to make upon the boasting presumption of the latter sentence, remarking merely, in the mean time, that a more complete delusion never entered into the mind of man than that which seems to have taken possession of our author, when he imagines that he has made any thing like an analysis of the subject of which he is treating. His process has been on the contrary purely synthetical, and we fear that rarely have such weighty and important conclusions been based upon such a miserably scanty foundation.

The experimental part of this investigation commences with three experiments, from which our author derives the following fact: "*that the mean time spent in filling a barrow, wheeling it four runs of twenty-five yards each, and returning with the empty barrow, is* 5′ 45″. He then gives two experiments which determine 7′ 20″ *for the time spent in filling one barrow, wheeling it four runs of twenty-five yards each, and returning with the empty barrow,* including *also the time spent in filling the same barrow a second time, and wheeling it forward two runs.* Hence taking the difference of these two times, the author makes 7′ 20″—5′ 45″=1′ 35″, the times which elapsed in filling one barrow and wheeling it forward two runs, or which is the same thing, 1′ 35″= the time of filling a barrow, wheeling it one run, and returning with the empty barrow.

It is next assumed that the time of filling the barrow must be equal to the time of wheeling over one stage, and returning with the empty barrow. Hence $\frac{1' 35''}{2} = 67''$ (17″) the time of filling each barrow. The whole time occupied in making the experiments from which this result has been derived is somewhat less than 32 minutes, this being the sum of the observed times in the whole five experiments.

We need scarcely pause to notice how completely inadequate must be a limited experience of this kind as a standard for estimating either the expense or rate of progress in removing earth by barrows. As well might a traveller estimate his rate of progress from the beginning to the end of the journey, by observing his speed during some particular half hour. As well might a vessel's rate of sailing for weeks, months, or for a whole year be infallibly prognosticated from the information afforded by a simple page of the log book.

We challenge all the examples since the beginning of time, where grand conclusions have been drawn from insufficient premises, to bear comparison with the instance which our author has here furnished. Telford, Rennie, Mylne, Smeaton, and all the other great engineers under whose guiding genius not a few great earth works have been executed long ere railways were thought or heard of, how many a laborious inquiry, and how many a painful lesson would have been saved to you, had the experience been yours, of the half hour during which these important experiments were made.

It is due to our readers, however, to inform them that there are three more experiments, "conducted," say the author, "in a different manner." The difference consists in this, that these experiments are made upon a number of barrows together, instead of single barrows, as in the first set of experiments.

We relate this second series of experiments in the author's own words, and we make no comment upon them, as our readers will perceive at once that they are equally insignificant in point of extent with the first five which we have noticed at length.

Experiment 1.—Twenty-four barrows were filled, wheeled forward two runs, and tipped, in thirty-eight minutes and forty-eight seconds: which is the same in effect, as if they were filled, wheeled *forwards and backwards*, and tipped upon *one* run, during the same time.

Experiment 2.—Eighteen barrows were filled, wheeled forward one run, and brought back empty again, in twenty-five minutes, and forty-two seconds.

Experiment 3.—Eleven barrows were filled, wheeled forward upon two runs, and emptied, in eighteen minutes: which is the same in effect, as if they were filled, wheeled forward, emptied, and brought back, upon one run.

From these experiments it is determined that 1′·37″ is "the mean time which elapsed while a single barrow can be filled, wheeled one run, emptied, and brought back;" we are then told that 37 barrow loads can be wheeled on each road per hour. And our author, assuming, we suppose, the weight of all earths to be the same, derives from this fact the performance of each single barrow road, and upon any number of these working together. It is obvious that this assumption is most erroneous, as for example, the specific gravities of different soils may be stated thus, common mould 1·46, sand 1·52, sandy loam 1.6, clay or marl 1·712, gravelly sand 1·784, gravelly clay 1·93, common land gravel 2·017, rough water gravel 2·32, common sand stone 2·5, lime stone 2·7.

Thus, supposing that a man can wheel of common mould 37 cube yards in a day of 10 hours, which accords with the author's statement of his performance, he would only be able, with the same labour, to wheel 23 cube yards of rough water gravel. And, without multiplying examples to show the fallacy of any assumed standard, such as the author derives from his experiments, it may be observed, in general terms, that the quantity which can be wheeled will be inversely proportionate to the specific gravity of the stuff, and not by any means constant for all soils.

Another error into which the author has fallen, is that of taking 25 yards as the invariable length of a run. Our own opinion is, that this is too great a length for a level road; but, besides this, it is most important to notice that, in order fairly to apportion the labour of wheeling, the length of each man's run must vary according to its rate of inclination. In practice this is always attended to, the workmen usually being quite expert at fixing the position of the stages or resting-places, according to the slope of the run.

There is yet a third error which we cannot pass over, namely that of supposing two men always to be employed in filling, during the time of the wheeler's absence, so that one loaded barrow may always be ready for him each time he returns to the filling place. It is evident, and experience, moreover, has shown, that in some soils, such as light sands, a single filler will keep the wheeler constantly going, whereas in others, such as stiff clays and marls, three and even four men are necessary for the same purpose.

Of such consequence, in an inquiry of this kind, are the particulars which, as we have seen, the author has omitted to consider, and so fallacious are the general assumptions in which he has indulged, that we cannot refrain from expressing our decided disapprobation of this second part of the work.

We have only further to remark, that with all these faults in his own work, it is scarcely to be borne that such a lofty contempt should be evinced by the author for all that has ever been written before on this subject. Certain we are, and we are happy to say it for the honour of the profession, that there are not wanting many, many practical men, who, if they have never *written* on the subject, contain in their own heads, or perhaps in the shape of private memoranda, such a complete acquaintance with the system of barrow work, that they can predict accurately, on examination of the locality, every circumstance of expense, time of execution, number of men and quantity of materials required, in any particular work.

This, we presume, would indicate at least as much knowledge of the subject, in all its bearings, as the author of this inquiry could possibly imagine any person capable of acquiring from the pernsal of his work. But how different in value must that knowledge be which is obtained by the practical experience of years, from that which is based upon the experiments of a few hours' duration. The information of the practical man consists of gross results, with all the attendant circumstances of which he is, or ought to be, acquainted; and his method of arriving, where necessary, at the separate details, is really analytical, and so directly opposed to the process of establishing gross results from separate experiments in detail.

LITERARY NOTICES.

A very able work "on the Law and Practice of Letters Patent for Inventions," by Thomas Webster, Esq., has just been published, we shall notice this work in the next month's Journal.

Mr. Whishaw's long expected work on the Railways of Great Britain and Ireland has at length appeared. We received it so late in the month that it precludes our examining it with the attention which it deserves, we must therefore postpone our remarks, excepting so far as saying, that it contains several engravings of Locomotive Engines, all the rails in use, and other details connected with railways, very beautifully executed; with valuable tables showing the results of practical experiments as to the actual working of English Railways.

The History of the London and Birmingham Railway, by Lieut. Lecount, is a republication of his interesting and valuable contributions to Roscoe's illustrated work on that subject.

The Building-ground Calculator, by E. W. Garbett, Architect, contains a series of Tables for ascertaining the value of Land per acre, when divided out into plots of various depths from 100 to 300 feet, at prices from 5½*d.* to 14*s.* 5½*d.* per foot frontage, or £10 to £105 per statute acre.

NEW INVENTIONS AND IMPROVEMENTS.

Improvements in the construction of steam boilers and engines, and of locomotive carriages: patented by Frank Hills, of Deptford, manufacturing chemist, November 5, 1840.—These improvements are numerous and difficult to explain without the illustrative engravings; a tolerable idea of their nature, however, will be conveyed by the following list of the ten claims;—1. The employment of a series of vertical tubes partly filled with water, and having small pipes passing down their centres, forming passages for smoke or heated air. 2. The employment of a series of vertical tubes which are closed and unconnected at the top, and open at the lower end, which communicates with a chamber, or series of chambers, partly filled with water; and which tubes have small pipes passing up their centres, for the purpose of conveying the steam to the boiler with which they are connected. 3. The use of flat chambers connected by means of pipes, filled with water, the upper portion of such chambers, forming steam chambers. 4. The employment of wooden felloes to wheels used for locomotive and other carriages, which felloes are enclosed between two vertical wrought iron rings, to which the spokes of the wheel are welded. 5. The employment of hollow arms, which are open at the ends on which the wheels revolve, and through which opening the driving shaft passes. 6. The employment of collars or enlarged pieces running in bearings, which have a groove and are connected with the brass containing oil, in order that a regular supply may be afforded to the working parts requiring the same. 7. The method of filling up the space between the arms of the (Hero's) engine. 8. The method of reversing the motion of the engine by employing two sets of arms, with other apparatus hereafter described. 9. The mode of inserting a wooden block or other slow conductor of heat between the tube which communicates the motion and the driving shaft. 10. The mode of imparting motion to an engine shaft, by means of an arm or crank being fixed on the middle of such shaft, and driven by one of two connecting rods alternately, which are both driven by the piston rod and guided by radius rods.—*Mechanics Magazine.*'

Improvements in wheels and locomotive engines to be used on railways: patented by David Gooch, of Paddington, Engineer, Nov. 20, 1840.

These improvements consist simply in forming the outer or working surface of the tire of engine and carriage wheels, of steel, which may be made of any required degree of hardness. The application of steeled tires to wheels used on railways, (it is said) has hitherto been prevented by the difficulty of forging and fixing them. The following method of surmounting this difficulty is Mr. Gooch's:—A faggot of wrought iron bars are worked and hammered, or rol ed into a solid piece, and afterwards drawn out in rolling, or under the hammer upon an anvil, having a groove to form the flanch, into the state of rim iron. An indentation or hollow is then made, lengthwise of the bar near the flanch, in order to prepare it for the reception of the steel. A faggot of steel bars is then so arranged, that when hammered and worked into its proper (wedge) form, the edges of the bars shall form the broad surface of the tire. The two bars of iron and steel thus prepared are then welded together, and afterwards formed into a rim or hoop of the form required. The wheel being prepared in the usual way, and its rim turned, it is laid flat on a true face-plate, and the tire being regularly and uniformly heated red hot, is put round it. The whole is then plunged into cold water or other frigorific mixture, which contracts the tire and hardens the steel. Holes having been previously drilled through the steel hoop, are now continued through the rim of the wheel, and both are rivetted together. Or, the rivets may be advantageously dispensed with when the steel is driven well into the indentation prepared for its reception. "Many important advantages," says this patentee, "will arise from the use of steeled tires on railways; besides the economy immediately resulting from the greater durability, a vast reduction will be effected in the wear and tear of the engines, the carriages and the rails; while a corresponding improvement will arise in the comfort and safety of travellers. The intense friction to which the wheel is subjected, occasions a rapid wear and tear of the iron tire, productive of most injurious consequences. An indentation is soon formed by the rails on the tire, which disturbs the action of the wheel, and destroys smoothness of motion. The same causes derange the action of the engine itself; every revolution of the locomotive wheel brings an irregular strain on all the parts, which materially increases the wear and tear to which they are liable. Great damage is also done to the railway, on which the wheels at every revolution act like so many ponderous hammers. It has been found advantageous to make the working surface of the wheels conical, diminishing from the flanch; but the conical surface of the iron tire is soon worn down, and the wheel made conical the reverse way, causing a serious loss of tractive power and increase of friction on all the parts affected. By the use of steeled tires these evils are henceforth to be avoided, the extreme hardness of the surface enabling them to endure without injury the action of the rails for a considerable length of time."—The claim is, 1. The mode described of forming and hardening steeled tires of wheels to be used on railways. 2. The use of steel in the tires of engine and carriage wheels for railways.—*Mechanics' Magazine.*

An improvement or improvements in the mode of resisting shocks to railway carriages and trains, and also in the mode of connecting and disconnecting railway carriages: also in the application of springs to carriages; patented by William Henry Smith, late of the York-road, Lambeth, but now of 20, Rockingham-row, West, New Kent-road, Engineer, dated Nov. 28, 1840.—The first improvement consists in applying to railway carriages certain combinations of machinery or apparatus, affording an increased length of elastic resisting power, with a consolidated action of the same, calculated to obviate the present liability to danger. The second, a peculiar mode of connecting the engines or carriages, whereby they may be more readily attached to each other, or instantly detached, thus placing them more completely under the control of the engine-man or conductor, by whom the connect on may be broken (without his leaving the foot-plate) in case of the engine getting off the rails or meeting with any other accident; or a solid connection may thus be formed between the carriages, causing a simultaneous action of the whole train upon one point of resistance, thereby lessening the amount of spring or other elastic resistance required, and at the same time ensuring greater safety and efficiency of action. The third, consists in a certain application of the vertical or side springs, by which is obtained in a greater degree an universal action of the carriage, presenting an increased elastic resistance in the direction of the shock, whether lateral or vertical. In the first case, a series of helical or other springs are placed in parallel rows, side by side, beneath one of the carriages; a single buffer-bar extends, by connection, through the whole length of the train, and projects about five feet beyond the carriages at each extremity. This buffer-bar is connected to two cross arms, which abut against the two ends of the series of springs already mentioned. A buffer at the end of the bar receiving any shock, it is transmitted along the bar to the cross pieces impinging on the springs, which present an elastic resistance to such pressure. As these springs can be acted upon from either end, should a collision occur from one train overtaking another, both would, if thus equipped, be found unhurt, the consolidated resistance in each being brought simultaneously into action. Another mode of resisting sudden shocks is by means of a male screw upon the buffer-bar running along the under side of the carriage frame, having a quick thread "so as to fall by its own gravity," and turn freely in a nut or collar firmly affixed to the carriage. Any shock, it is said, would be transmitted through this collar in a much less degree (proportioned to the angle of its thread). The end of the screw is attached to a strong verge spring, which increases the resistance to the turning of the screw as it is wound up, so as completely to overcome the shock. The screw is acted upon by a buffing-bar. "The main value of this part of my invention," observes the patentee, "is, that the spring is affected but in a small degree by the amount of shock endured; its principal portion being received in the collar, and the resistance not increasing in the same proportion against the spring as in the ordinary methods: but by the screw's application, I calculate, five-sixths of the effect of the concussion would be received by the collar (*ergo: by the* CARRIAGE), and the same proportions to any extent." A third method of resisting shocks is by means of an hydraulic apparatus, consisting of a large close cylinder filled with water, placed under the carriage; a piston works loosely in this cylinder, the piston rod passing through a stuffing box, and forming the buffing bar; a passage under the cylinder, which connects its two ends, is closed by a cock. On encountering a shock, the buffer-bar forces the piston along in the cylinder, the water rushing from before it through the open cock, the contracted orifice of which impedes its progress and checks the motion of the piston. As the piston rod is pushed in, a connecting rod passing from it to the cock closes the latter, when the water can only escape by the sides of the piston, thus offering a still greater amount of resistance. The piston is capable of working either way, according to the end of the train from which the shock is received; and owing to the piston not fitting tightly, there will be no liability of it or the cylinder receiving any injury. There is a reacting spring for restoring the piston to its original position.—The mode of connecting and disconnecting railway carriages is by the following arrangement:—A connecting bar is attached to the engine by a pin joint, and kept in the right position by a staple pendant from the foot-plate; at the other end of this bar there is a piece projecting upwards. A bell-mouthed aperture is let into the front frame of the tender or carriage, which guides the before-mentioned bar into the recess in case of any variation of the relative positions of the carriages. On pushing the carriage, &c. up to the engine, the bar enters the aperture, pressing down a strong spring until the projecting piece of the bar enters a slot or cavity prepared to receive it, when the spring rises and forms a permanent connection. In order to disconnect the engine, it is only necessary to press with the foot upon a small rod, which, acting on the projection, forces down the spring and allows the bar to be withdrawn.—The new mode of applying springs to carriages of every description, consists in adapting four sets of helical springs, to work obliquely between the wheel axles and carriage frame, being inclined at the angle of about 40° from each other towards the ends of the carriage. The object of this arrangement is (said to be) to receive the jerk in whatever way it may come, either from the wheels or the buffers, and transfer it to the opposite spring, which together (the one by compression, the other by expansion) present an additional resistance to the action of the shock. These springs have also a double vertical action resisting shocks either from above or below.—*Ibid.*

Improvements in railway and other propulsion; patented by John George Shuttleworth, of Fernly-place, Glossop-road, Sheffield, gentleman, Nov. 28, 1840.—The contrivance of this gentleman bears a very close resemblance, in many parts, to the atmospheric railways long before the public, except that in the present instance the patentee proposes to employ a denser fluid (water) as the motive power. A horizontal main or tube is laid along the line between the rails, having a slot or opening on its upper surface: this aperture is smallest at the top, and expands downward. A piston fits the interior of this tube, and terminates in a peculiarly formed guide-neck, for taking up and applying to the aperture in the pipes a continuous flexible valve or stuffing of india rubber or other suitable material. In front of the guide-neck there is one vertical and one horizontal wheel, to guide the piston steadily along the line with the smallest possible quantity of friction; while a thin metal plate passes up through the opening, and is attached to a railway carriage of the ordinary construction. At the commencement of the line, a vertical pipe conveys a column of water on to the horizontal main, through a valve or cock opened or shut at pleasure. The efficiency of this agent may be produced by the pressure of an elevated reservoir, or by the application of steam power to force it into the pipes. On turning the cock the water rushes into the main, and drives the piston, with the carriage to which it is attached, forward; the flexible valve, which lies along the bottom of the main, but passes through the guide-neck and up over the piston, is raised as the piston travels along, and forced into the opening of the pipes, where it is kept by the pressure of water behind the piston.—The claim is—1st. The application of the power of a column or body of water acting against a piston in a tube, to which piston a railway carriage, or other object to be propelled, is fastened for the purpose of propulsion. 2nd. The improved guide-neck to the said piston for raising and conveying to its proper place the flexible valve or stuffing required to fill the slot or space left open in the upper part of the propelling tube for the passing of the plate.—*Ibid.*

Improvements in the manufacture of certain descriptions of cement: patented by Richard Freen Martin, of Derby, gentleman, Dec. 2, 1840.

The improvements which form the subject of this patent, relate more particularly to those descriptions of cement for which a former patent was obtained, dated Oct. 8, 1834, but are also applicable to other cements, as set forth hereafter. In the former patent, in order to produce certain hard cements, it was directed that gypsum, either in its natural state or as plaster of Paris, or limestone, or chalk, or lime, in the state of powder, should be mixed with a solution of any strong alkali neutralized by an acid, (American pearlash and sulphuric acid being preferred) and that water should be added to the mixture till it was in a fit state for casting or moulding into cakes, and to be subsequently dried and burned. The patentee has since discovered that the said processes may be facilitated and the cost of them reduced in the following manner:—

First, instead of employing alkaline and acid solutions, the acids and alkalies are to be used in the solid state, either added separately or previously combined together, and no more water employed than the materials themselves contain.

Secondly, in certain cases the addition of the alkali, or both the acid and the alkali are dispensed with, and the quantities of these ingredients incorporated in the substances themselves are depended upon, to form the bases of the cements. In carrying out the first improvement, a quantity of pearlash is dissolved in water, to which is added a sufficient quantity of sulphuric acid to form a neutral compound; this mixture being evaporated to dryness, leaves the required compound in a solid state.

When it is desired to add the acid and alkali separately in a solid state to the gypsum, chalk, &c., pearl-ash is used and dissolved, or where cements of superior density are required, some of the alkaline earths (barytes for instance) are employed. The acid constituent is obtained by using sulphur or sulphuric acid in combination with other matters, as pyrites and mineral sulphates, or some solid substance containing both an acid and an alkali, as alum, &c. In this case it is necessary so to regulate the acid and alkaline proportions, that they shall always exactly neutralize each other. The acid and alkaline matter being provided in any of these ways, is to be mixed with gypsum, or lime-stone, or chalk, in the following proportion:—to any given quantity of either of the foregoing or similar substances, add as much solid alkali and acid as that for every part by weight of alkali (of the strength of the best American pearlash) there shall be about 150 parts of the gypsum, &c., or of the gypsum and lime combined in equal proportions. These materials are then to be ground together into a fine and well-mixed powder, which is to be first dried and afterwards calcined in suitable revolving cylinders. By the second improvement, cement may be formed by combining gypsum and lime with a third substance containing or producing an acid; or by combining gypsum and lime alone, without the addition of any third substance either of an acid or alkaline quality. 1. About two parts by weight of gypsum are to be mixed with one part of lime, and for every 100 parts of lime or thereabouts, there is to be added one part of sulphur, or of some substance from which acid is produced, regulating its quantity according to its superior or inferior acid-producing qualities. 2. To make a cement from gypsum and lime alone, these are to be mixed in such proportions as that the moisture given off in the process of calcining them together by the gypsum, shall be just sufficient to slake the lime. When the London grey-stone lime is used, about two parts of gypsum are required to one part of lime. In all cases the materials are to be ground and calcined as before stated. The mode of using the cements thus formed is the same as set forth in the specification of the former patent. It is found to be advantageous to use none of such cements in a fresh state.—*Ibid.*

Important to Mariners.—We have lately read so much of the calamity of shipwreck, that any attempt to lessen its horrors, must be hailed as a real blessing. Few that have not heard of Captain Manby's Life-Preserver. We have just witnessed a successful attempt of simplifying the principle upon which that valuable discovery is founded, so as to be available wherever a common cannon and a piece of rope are at hand. There is no occasion for a mortar or a rocket, a common ship gun will answer the purpose. The experiment was lately tried on the sea shore, about a mile southward of Aberistwith. We had been previously informed that Mr. Page, the superintendant of the Harbour Works, had, at the instance of the Harbour Trustees, directed his attention to the subject, and we are glad to state with the most perfect success. The machinery is the simplest possible. A common twelve pounder that belonged to the old *Agenoria*, was placed on the store, elevated to 40 degrees, and loaded with a nine ounce charge of powder, with a well fitted wadding. Before us lay a long coil of rope, ¾ inch diameter, with a stout piece of wood or plug, of the length of a common spade fastened to it. This plug is intended to be put in the mouth of the gun. The ploblem to be solved, was to project this piece of wood over the breakers before us, so that should a vessel have struck there, as we remember one to have done about 18 months since at that very spot, and the sea should be too high for any boat to live in the surge, a rope might be sent from the land to the ship, or from the ship to the land. The simplicity of the whole affair struck us extremely, and no alchymist waited with more anxiety the moment of "projection" than we did the firing of the cannon. Those that know anything of these matters will understand us when we say that our great apprehension was, lest the rope should *snap*—that being the great difficulty to be got over in these experiments. But our apprehensions were quite needless. The gun was fired once, twice, thrice, and the plug and rope were hurled beyond the breakers without a thread of the latter breaking or straining. Its length was 160 yards; but it might be extended by increasing the charge of powder. That peculiarity of the apparatus upon which the engineer mainly depends for counteracting the tendency of the rope to break is, by strengthening about two feet of that part of it which comes in contact with the plug: this is done by adding to it four others of the size of lead lines, and which are bound together with pieces of spun yarn, and fastened to the plug with four small staples, the main rope or a bit of chain instead, being fastened to it, by a ring and thimble. Thus strengthened, the rope is found sufficiently strong to stand unharmed against the jerk with which it is projected from the cannon, and this it could not do without the four extra supporters. Upon enquiring of the engineer why he preferred a wood plug to a rocket or ball, he stated that in case of a man overboard, the plug would *float*, and that also in case of being fired *from* a vessel, it would from its buoyancy be carried on shore by the mere action of the sea. Its extreme simplicity is its great recommendation. There are few vessels without a cannon of some size on board, and a hand-spike or capstan bar will answer the purpose of a plug perfectly well. We should have stated that the wetness of the rope after the first discharge was found to be of no inconvenience, but care should be had in coiling it properly, so as to enable it to play out with facility.—*Carmarthen Journal.*

New Code of Signals on the Great Western Railway.—The whole of the engine-drivers, stokers, guards, conductors, and other persons employed on the railway throughout the line were assembled at the engine-house of the Paddington station last week, when a new code of signals, prepared by Mr. Brunel, the engineer-in-chief to the company, were fully explained to them by that gentleman, and several of the signals were put into practical operation. A special train was sent from the Paddington to the Farringdon-road station, to convey the engineers, stokers, guards, &c., at that end of the line to town. By the adoption of the new code, distinct and immediate intimation will be given to the engine-drivers and others of the least obstruction along the line.

Eastern Counties Night Signals.—The manager of this company, R. Hall, Esq., has invented an ingenious system of night signals for the Eastern Counties Railway. On the back part of the chimney of the engine is placed a reflector, so inclined that a light pressing from the top of the train will be reflected down upon him. The two guards sent with every train are provided, besides their common lamps, with two signals consisting of blue and red lights. Upon the removal of a piece of tin, a screw presses upon some fulminating powder, which immediately ignites the signal, and gives out a most intense light for some time, which, falling on the engine reflector, is sent down concentrated upon the engine man, so that he is immediately aware of the signal. The blue light indicates caution, and the red light danger. The light is so exceedingly intense as to give a brilliant illumination all around, and the men who have tried it declare if they were asleep it would wake them. The present signals throw off several luminous balls in succession, but Mr. Hall will in future use the light only. At the junction of the Northern and Eastern, and other parts of the line, the men are provided with these signals. A sliding reflector is added to give greater power to the light, but from what we have seen, we are of opinion that that is unnecessary, as the lights are so strong that they may, in our opinion, be seen for 10 or 15 miles off.—*Railway Magazine.*

LAW PROCEEDINGS.

PATENT LAW—AMENDMENT OF SPECIFICATION.

IN THE MATTER OF JOHN SHARP'S LETTERS PATENT.

In the Rolls' Court, Tuesday, Dec. 22.

Lord Langdale pronounced his decision upon the petition of Joshua Wordsworth (reported in last month's Journal, page 428,) for expunging from the memorandum of alterations in the specification of Sharp's letters patent "for machinery for converting rope into tow," certain portions which were alleged to be in substance descriptive of the same machinery as was invented by the petitioner. The petition stated that Sharp had, under the 5th and 6th Will. IV., c. 73, with the leave of the Solicitor-General, entered with the Clerk of the Patents certain memorandums of alteration of part of his specification, which alterations the petitioner, Wordsworth, complained of as a new arrangement of machinery, extending Sharp's patent to what the petitioner alleged was in substance his own invention for heckling and dressing flax, &c., as described in his specification. His Lordship said he had delayed his decision for the purpose of collecting information as to what had been done by the Court respecting amendments of specifications, and it appeared it was usual to make amendments in the enrolment in cases where there were clerical errors *negligenter per incuriam vel ex lapsu calami scriptoris*, and this had been done, sometimes by reference to the Master of the Rolls, by the Lord Chancellor, and in one instance by the Lord Chancellor himself upon an order from the Crown, sometimes by writ of Privy Seal, sometimes by consent of the Attorney-General, and sometimes by sign manual. In all modern instances the alterations had been merely clerical. It did not appear that the Master of the Rolls as keeper of the records had ever exercised any authority in matters of this kind when the error complained of was not merely clerical. He was clearly of opinion that he had no authority to make the alteration asked for, and he must dismiss the petition with costs.

The Queen v. the Grand Junction Railway Company.—MANDAMUS.—*Court of Queen's Bench, November* 15.—Sir F. Pollock applied for a rule, calling on the Grand Junction Railway Company to show cause why a writ of mandamus should not issue, commanding them to obey the enactments of the 19th section of the Act 3 Victoria, cap. 19, which was as follows:—"And be it further enacted, that the charges of the said recited Acts, or either of them authorised to be made for the carriage of any passengers, goods, animals, or other matters or things to be conveyed by the said company, or for the use of any steam power or carriage to be supplied by the said company, shall be at all times charged equally and after the same rate per mile or per ton per mile, in respect of all passengers and of all goods, animals, on carriages of a like description conveyed or propelled by a like carriage or engine passing on the same portion of the line only, and under the same circumstances, and no reduction or advance in any charge for conveyance by the said company, or for the use of any locomotive power to be supplied by them, shall be made, either directly or indirectly, in favour of or against any particular company or person travelling upon or using the same portion of the said railway, under the same circumstances as aforesaid." He made this application at the instance of Messrs. Pickford, the carriers, who would, unless the court interfered to protect them from the company, be obliged either to give up the carriage business altogether, or to carry it on without deriving any profit from it. It appeared from the affidavits, that the usual method of transmitting goods from London to Liverpool and Manchester, was by the London and Birmingham Railway to Birmingham, thence by the Grand Junction Railway to Newton, and from Newton by the Liverpool and Manchester Railway to those towns respectively. The Grand Junction Company had, it appeared, granted to Messrs. Chaplin and Horne the accommodation of permitting the trucks on which their goods were placed to pass at once from the London and Birmingham line to the Grand Junction line at Birmingham, and from the Grand Junction line at Newton to the Liverpool and Manchester line, without any change of carriage or unloading, but since September last had refused to afford similar facilities to any other carriers; and when applied to by Messrs. Pickford on the subject, had informed them that they could not afford them the desired accommodation unless they paid something additional for it, while it was afforded to Chaplin and Horne gratuitously. The expense of loading and unloading the trucks would be about £5. a day additional to Messrs. Pickford, besides the loss of time which it would occasion them. It appeared also that the company at the Camden Town station charged 65s. a ton for the carriage of goods to Liverpool or Manchester, but they made Messrs. Chaplin and Horne an allowance of 10s. a ton for collecting and distributing the goods in London, which allowance they refused to make to Messrs. Pickford. There was a clause in every railway act empowering other persons than the company to start locomotives and trains on the railroad, but this was a complete dead letter, inasmuch as the company might refuse such persons the use of their pumps or of their coal depots, and had also unlimited power in regulating the times of starting, &c., of such engines. The fact was, the company was aiming at a complete monopoly of the carrying trade, which they would certainly acquire unless they were compelled to obey the enactments of the clause in question.—Mr. Justice Patteson granted a rule to show cause.

PROGRESS OF RAILWAYS.

Manchester and Leeds Railway.—Completion of the Summit Tunnel.—On the 9th ult. the last brick of this great undertaking was keyed-in by Barnard Dickinson, Esq., the resident engineer, who was presented on the occasion (by J. Stephenson, Esq., the contractor) with a silver trowel, the gift of the inspectors and sub-contractors on the works. The tunnel was lighted by torches, and a large company of ladies and gentlemen were present to witness the ceremony. At twelve o'clock, Mr. Stephenson, accompanied by his manager, Mr. G. Mould, Mr. Dickinson, and other gentlemen connected with the company, entered the tunnel amidst the acclamations of the party assembled, when Mr. Stephenson, in presenting the trowel, congratulated Mr. Dickinson on the successful completion of a work, which, but for the united skill and enterprise displayed in its execution, would have been insurmountable. Mr. Dickinson then finished this great work, by keying-in the last brick, amidst the cheers of the spectators; after which he delivered an animated address, in the course of which he observed that some idea might be formed of the amount of labour employed in the construction of the tunnel, when he informed them, that had it been left to the unassisted efforts of one man, it would have taken him as much time to complete it as had elapsed between the commencement of the Christian era and the present day, namely, one thousand eight hundred and forty years! At the conclusion of the ceremony the company were invited to partake of a cold collation at the Summit Inn, when several excellent speeches, having reference to the completion of the work, were delivered in the course of the evening. The workmen were also regaled with abundance of good cheer within the tunnel.—*Midland Counties Herald.*

Oldham Branch Railway.—On Saturday, the 12th ult., a number of the directors of the Manchester and Leeds Railway, accompanied by their principal engineers, visited Oldham, and examined the country between Oldham and the main line, for the pupose of determining the best course for the Oldham Branch Railway.

Contemplated Railway through Blackburn.—We rejoice in being enabled to state that the first step has at length been taken to secure to Blackburn and the surrounding district the advantages of a railway communication with the North Union and Manchester and Leeds lines. On Thursday last, a highly respectable meeting was convened by circular, at the Hotel, in King-street, to confer with Mr. Stephenson, the eminent engineer, and two other gentlemen of the same profession who accompanied him, upon the subject. The meeting was well attended, and but one feeling appeared to pervade the company, viz., an anxious desire for the accomplishment of the object in view. The engineers exhibited a map of the different railways, with the proposed line from the North Union at Preston, through Blackburn, Accrington, and Burnley, to the Manchester and Leeds line at Todmorden, a distance of about twenty-six miles.—William Turner, Esq., M.P., having been called to the chair, a long conversation took place between Mr. Stephenson, the chairman, William Feilden, Esq., M.P., Joseph Feilden, Esq., P. E. Towneley, Esq., James Neville, Esq., and others, the result of which was the appointment of a committee, to confer with the directors of the North Union and Manchester and Leeds Companies, and also with the owners of property on the proposed line; and to ascertain what pecuniary assistance they were disposed to render towards obtaining a survey, from Preston to Burnley, the cost of which was estimated at £700. The ground from Todmorden to Burnley, we believe, has already been surveyed; and it is understood that the Manchester and Leeds Company are disposed to extend their line to Burnley, provided another company be formed to continue it through Blackburn to Preston. Should this expectation be realised, and there appears no reason to doubt that it will, it will do much to facilitate the proposed undertaking.—*Blackburn Standard.*

PUBLIC BUILDINGS, AND IMPROVEMENTS.

Fresco in the New Houses of Parliament.—Cornelius, the celebrated German painter, is, it is said, on his way to this country, where he is to be consulted as to the frescos of the new Houses of Parliament. Certainly Cornelius has no merits which can give him a superiority over Englishmen in the representation of English scenes. We have no illiberal prejudices against foreign artists, and should be the first to recommend the purchase of their works for our public collections, but we think that when any great national commemoration is the subject, the employment of foreign artists is a desecration of the monument. It is thus also we view the employment of Marochetti at Glasgow. How differently would Titian, Murillo, Rubens, Rembrandt or Lebrun represent the English people in the performance of the same action—however great might be the skill of the artist, he would be wanting nationality. How are we ever to become a great nation in art, when we are deprived of the only opportunity of giving scope to the powers of our artists!

Wesleyan Chapel, Great Queen Street.—The small portico which has been attached to the front is completed.

British Museum.—A temporary communication has been opened through the Long Gallery, so that the visitor is now able to proceed all round the Museum. In the upper Egyptian room are two fine specimens of Egyptian sculpture in *intaglio rilevato*, highly deserving of attention.

Clifford.—On Monday the 23rd of November, the foundation stone of a new church about to be erected at Clifford, in the parish of Bramtram, in the West Riding of the county of York, was laid by Miss F. E. Fox, daughter of George Lane Fox, Esq., of Bramham Park. The ceremony was attended by many of the clergy and gentry in the neighbourhood. This church will be endowed with £1,500 by G. L. Fox, Esq., and the Dean and Chapter of Christ Church, Oxford, give £200 further endowment when the church is opened. It will be built by subscription in the neighbourhood and elsewhere, which has been liberally responded to. The design is furnished by Messrs. Atkinson, architects of York, to whose charge the building is intrusted. The church is intended to contain 300 persons in free pews, and there are no galleries. It is built in the form of a cross, with transepts; and a tower 70 feet high at the west end, and is of the pointed or early English style. The entire building is faced with free stone from the neighbourhood, and the cost when complete will be about £1050.

MISCELLANEA.

Cornish Steam Engines.—The number of pumping engines reported this month is 54. They have consumed 3193 tons of coal, and lifted 20 million tons of water 10 fathoms high. The average duty of the whole is, therefore, 53 million pounds lifted one foot high by the consumption of a bushel of coal. Richards's stamps at Wheal Vor works with hot condensing water. The boilers are being changed at Trelawney's engine, Wheal Vor, and are leaky at Tincroft; Wheal Prosper; Cargise; Taylor's, Woolf's, and Bawden's engines, Consols; and at Hocking's engine, United Mine.—*Lean's Engine Reporter, December 11.*

The Lake of Haarlem.—The King of Holland has just authorized the raising of an additional loan of three millions of florins for draining the Lake of Haarlem.

Proposed Suspension Bridge over the Haslar Lake at Portsmouth.—The usual calculation for the maximum load on each superficial foot of the platforms of suspension bridges is 70 lb.; but, as in the event of a crowd of persons assembling, the pressure may increase to nearly 100 lb. per foot, and by the passage of soldiers marching in regular time the strain may be greatly augmented, the projector assumed 200 lb. per superficial foot as the amount of load to which the platform might be subjected. The peculiar feature of this bridge is the substitution of cast iron chains for the wrought iron ones generally used. This deviation from the usual practice is adopted as a measure of economy, and with a view of increasing their stability and durability, cast iron being much less influenced by atmospheric action than wrought iron. Cast iron beams, when well proportioned, will bear a very considerable tensile strain. As these chains would be proved beyond the weight they are intended to bear, no doubt is entertained by the author of their security. The platform, which is formed of transverse iron girders, carrying cast iron plates three quarters of an inch thick, with dovetails falling into holes cast in the girders, is suspended by wrought iron rods 1½ inch square from two lines of chain only, as the strain is more easily brought to bear on them than on a greater number of chains. They are trussed laterally to prevent oscillation, and the balustrade is so constructed as to prevent the undulation so prejudicial to suspension bridges generally. To insure a perfect bearing, each pair of links of the chains are, in manufacturing, cramped together, and the holes bored out to receive the pins, which are turned to fit them accurately; they are of a larger size than usual, being four inches diameter, and a less number are employed. The piers on which the chains pass are of cast iron, 33 feet high above the level of the roadway.

The extreme length of the bridge is	632	feet.
The breadth of the roadway	17½	—
The clear waterway between the piers	300	—
The clear headway of the platform above the high water line	18½	—
Ditto ditto above low water line	33	—

The tension on the chains is calculated as equal to 991·4143 tons. To sustain this tension, the section of the chains is 256 square inches, and taking seven tons per square inch as the elastic limit of cast iron, the resistance of the chains will equal 1,792 tons, leaving a surplus of 800·6 tons after the calculated strain has been deducted from the real strength of the chains.—*Inventor's Advocate.*

STEAM NAVIGATION.

Messrs. Rennie are fitting their trapezoidal paddle-wheel to the *Africa*, a government steamer, instead of the common paddle-wheel, which has been heretofore used; this will form an excellent criterion of the comparative advantages of the two wheels. They are also fitting similar wheels to a vessel for the French government.

The Screw government have determined upon building a steamer for the purpose of trying the Archimedean screw; orders have been given to Messrs. Seaward for a pair of engines of 200 horse power each, for working the vessel.

A Gravesend steamer is on the stocks, which is stated will run from the Blackwall Railway to Gravesend within the hour. Messrs. Miller & Ravenhill have the construction of the engines in hand.

Rotary Engines.—Mr. Galloway is about applying a rotary engine of his invention to a new boat, for the purpose of working the screw without the necessity of using any intermediate wheels or gearing. The boiler is tubular, upon the locomotive principle. Messrs. Rennie are constructing the engines, which are now being put on board at their wharf at Blackfriars.—Another boat is being fitted with Bimns' patent rotary engines, of considerable power, and a tubular boiler, to work a wheel upon a new principle in the stern; the paddle-boards are suspended upon their axes, and allowed to work freely upon them without any stops, so that the paddle-board is always kept in a perpendicular position.

Launch of an Iron Steamer.—There was launched from Mr. Borrie's ship-building yard, Broughty Ferry, on Friday, 11th ult., an iron-built twin steamer, named the Princess Royal. This vessel has been built for the Tay Ferry Trustees, and is intended to ply between Dundee and Newport; her length on deck is 106 feet, by 34 feet in breadth, giving the extraordinary area on deck of 3604 square feet; she has been brought up to Dundee, and Mr. Borrie has commenced erecting her engines on board, which are of 80 horse power, and one in each of the hulls. The hulls are connected by the deck beams, and by six systems of transverse stays; the fastenings of these stays are placed within a few inches of the lead water line, for the more effectually maintaining the hulls in their true relative position; there is an intermediate space between the hulls, 10¾ feet in breadth, which extends the whole length of the vessel; there is only one paddle-wheel, and it works in this space nearly at the centre of the vessel, and is completely hid from view. When used as a ferry boat a twin steamer possesses many advantages, from her peculiar construction, over a single vessel; among these the most prominent are the great facility with which a twin steamer can take the quays from the absence of the paddle-wheels on the sides, great stability, easy motion in a cross-swell, great buoyancy, without having a great length and breadth of floors, and the sectional area of displacement not greater than what would obtain in a single vessel of the usual proportions. The form and finishing of this vessel are much admired, and will not fail to bring additional reputation to the contractor, whose eminence as an engineer is already fully acknowledged.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 27TH NOVEMBER TO 23RD DECEMBER, 1840.

Miles Berry, of Chancery-lane, Patent Agent, for "*certain improvements in looms for weaving.*"—Sealed November 27; six months for enrolment.

John Clay, of Cottingham, York, Gentlemen, and Frederick Rosenborg, of Sculcoates, in the same county, Gentleman, for "*improvements in arranging and setting up types for printing.*" November 27; six months.

John Condie, Manager of the Blair Iron Works, Ayr, Scotland, for "*improvements in applying springs to locomotive railway and other carriages.*"—November 27; six months.

George Holsworthy Palmer, of Surrey-square, Civil Engineer, and Charles Perkins, of Mark-lane, Merchant, for "*improved constructions of pistons and valves for retaining and discharging liquids, gases, and steam.*"—November 28; six months.

George Blaxland, of Greenwich, Engineer, for "*an improved mode of propelling ships and vessels at sea and in navigable waters.*"—November 28; six months.

Henry Bridge Cowell, of Lower-street, Saint Mary, Islington, Ironmonger, for "*improvements in taps to be used for or in the manner of stop-cocks, for the purpose of drawing off and stopping the flow of fluids.*"—December 2; six months.

James Robinson, of the Old Jewry, Manufacturer of Machinery, for "*a sugar-cane mill of a new construction, and certain improvements applicable to sugar-cane mills generally, and certain improvements in apparatus for making sugar.*"—December 2; six months.

Alexander Horatio Simpson, of New Palace-yard, Westminster, Gentleman, for "*an improved machine or apparatus for working pumps.*"—Communicated from a foreigner residing abroad. December 9; six months.

William Peirce, of George-street, Adelphi, Gentleman, for "*improvements in the preparation of wool, both in the raw and manufactured state, by means of which the quality will be considerably improved.*"—December 9; six months.

Charles Winterton Baylis, of Birmingham, Accounting-house Clerk, for "*an improved metallic pen, to be called the Patent Flexion Pen and Improved Penholder.*"—December 16; six months.

George Wildes, of the city of London, Merchant, for "*improvements in the manufacture of white lead.*"—Communicated by a foreigner residing abroad. December 16; six months.

James Davis, of Shoreditch, Engineer, for "*an improved mode of applying heat to certain steam-boilers.*"—December 16; six months.

John Steward, of Wolverhampton, Esq., for "*an improvement in the construction of piano-fortes, harpsichords, and other similar stringed musical instruments.*"—December 16; six months.

James Molyneux, of Preston, for "*an improved mode of dressing flax and tow.*"—December 16; six months.

Charles Bolton, of Farringdon-street, Gas Engineer, for "*a certain improvement in gas meters.*"—December 16; six months.

Hugh Graham, of Bridport-place, Hoxton, Artisan, for "*a new mode of preparing designs and dyeing the materials to be used in the weaving and manufacture of Kidderminster carpets, and for producing patterns thereon, in a manner not before used or applied in the process of weaving and manufacturing such carpets.*"—December 16; six months.

Joseph Beattie, of Portland-place, Wandsworth-road, Lambeth, Engineer, for "*certain improvements in locomotive engines, and in carriages, chairs, and wheels, for use upon railways, and certain machinery for use in the construction of parts of such inventions*"—December 16; six months.

Andrew Pruss D'Olszowski, of Ashley-crescent, Gentleman, for "*a new and improved level for ascertaining the horizon, and the several degrees of inclination.*" Communicated by a foreigner residing abroad.—December 16; six months.

William Tudor Mabley, of Wellington-street North, Mechanical Draftsman, for "*certain improvements in producing surfaces to be used for printing, embossing, or impressing.*"—December 17; six months.

Abraham Alexander Lindo, of Finsbury-circus, Gentleman, for "*improvements to be applied to railways and carriages thereon, to prevent accidents, and to lessen the injurious effects of accidents to passengers, goods, and railway trains.*"—December 18; six months.

Elias Robinson Handcock, of Birmingham, Esq., for "*certain improvements in mechanism applicable to turn-tables, for changing the position of carriages upon railroads, for furniture and other purposes.*"—December 18; six months.

Richard Coles of Southampton, Slate Merchant, for "*improvements in machinery for manufacturing tanks and other vessels of slate, stone, marble, and other materials, and in fitting and fastening such materials together.*"—December 23; six months.

Benjamin Baillie, of Henry-street, Middlesex, for "*improvements in locks, and the fittings and fastenings thereto belonging.*"—December 23; six months.

John Brumwell Gregson, of Newcastle-upon-Tyne, Northumberland, Soda-water Manufacturer, for "*improvements in pigments, and in the preparation of the sulphates of iron and magnesia.* December 23; six months.

Frederick Payne Mackelean, of Birmingham, and James Murdoch, of Hackney-road, Civil Engineers, for "*certain improvements of or belonging to tables, a portion of which is applicable to other articles of furniture.*" Partly communicated by a foreigner residing abroad.—December 23; six months.

George Thornton, of Brighton, Civil Engineer, for "*certain improvements applicable to railways, locomotive engines, and carriages.*—December 23; six months.

John Dickinson, of Bedford-row, Esq., for "*certain improvements in the manufacture of paper.*"—December 23; six months.

David Walther, of Angel-court, Throgmorton-street, Merchant, for "*certain improvements in the methods of purifying vegetable and animal oils, fats, and tallows, in order to render those substances more suitable to soap-making, or for burning in lamps, or for other useful purposes, part of which improvements are also applicable to the purifying of the mineral oil or spirit commonly called petroleum or naphtha, or coal oil, or spirit of coal tar.*"—December 23; six months.

John Jones, of Leeds, Brush Manufacturer, for "*improvements in carding engines for carding wool and other fibrous substances.*"—Communicated by a foreigner residing abroad. December 23; six months.

Joseph Barker, of Regent-street, Artist, for "*improvements in gas meters.*"—December 23; six months.

TO CORRESPONDENTS.

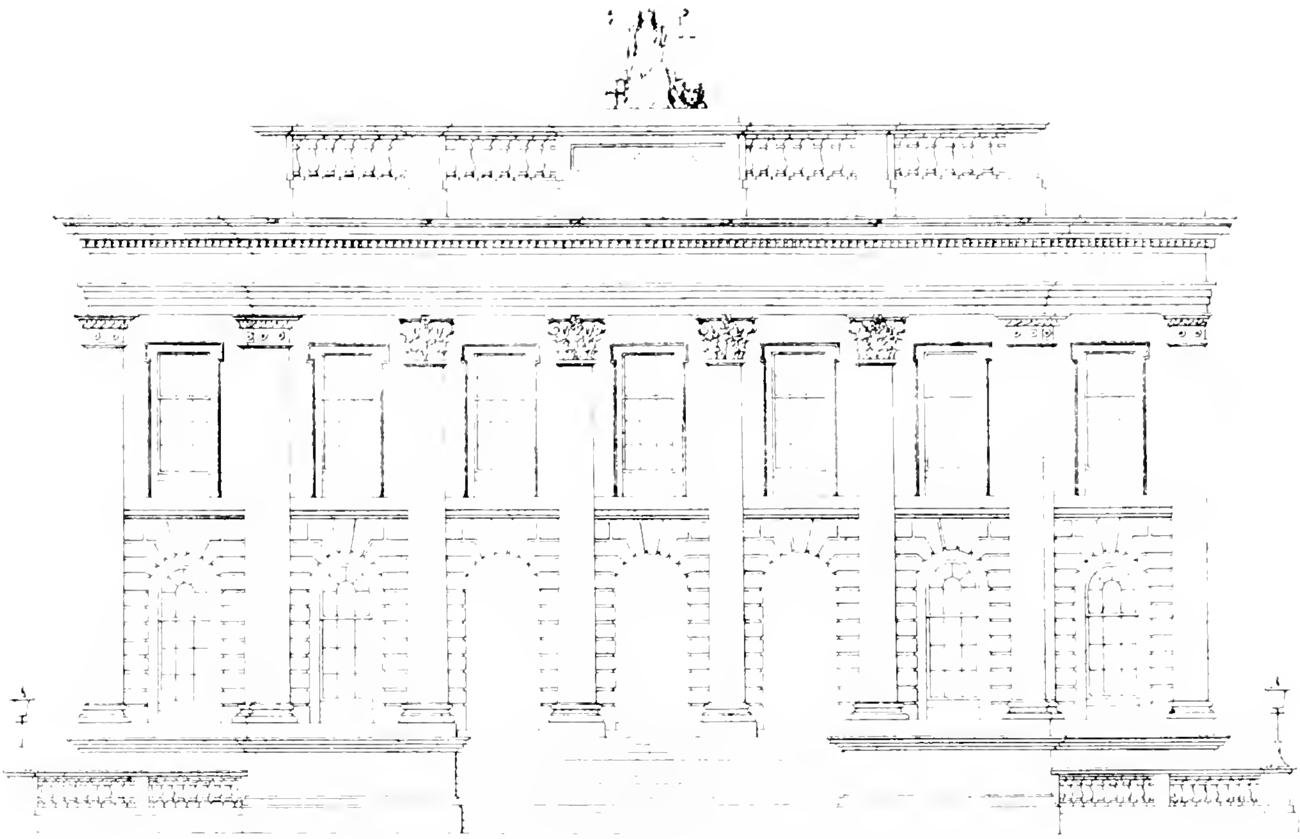
The drawings of the new town hall of Ashton-under-Lyne will appear next month.

Additional information on the Reform Club will be given when the building is entirely finished.

Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No. 11, Parliament Street, Westminster.*

Books for review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume.



ELEVATION OF THE NEW TOWN HALL, ASHTON-UNDER-LYNE

NEW TOWN HALL, ASHTON-UNDER-LYNE.

Architects, Messrs. Young and Lee.

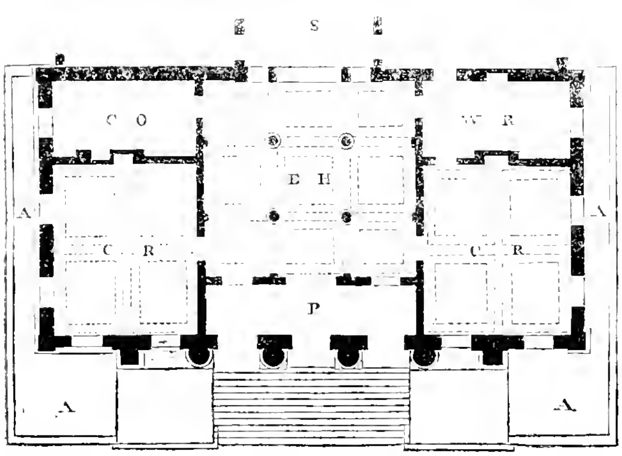
With an Engraving, Plate II.

A brief description of this building appeared in the No. for last July. It is in the Roman style of architecture, and consists in front of an attached Corinthian colonnade *in antis*, surmounted by a balustrade of the same order, which forms a parapet to the centre of the façade, and is crowned by a group of sculpture. The wings consist of a single interpilaster, and terminate above with a plain parapet. The two flanks of the building are alike; and consist simply of three windows in length, each similar to those in front, with antæ at the corners only. The attic wall with its cornice is also continued round the flanks. The internal arrangements, it will be seen, demanded that the front wall should form an uninterrupted line, and be pierced with windows along its entire length; and it was therefore considered preferable to have attached columns—an arrangement adopted in the Erectheium at Athens. The order itself is divided into two stories, and is elevated upon a lofty stylobate. Its proportions are chiefly taken from the Pantheon at Rome. A dentil cornice, instead of one with modillions, is used to save expense.

The design although making no pretensions to originality, is in keeping with the style adopted, and does credit to the architects, Messrs. Young and Lee of Manchester.

This building, erecting from designs by one of the architects engaged, Mr. William Young, of Manchester, is now on the point of being *roofed in*. It stands on the north side of the new market-place, Ashton-under-lyne; a town which, compared with its size, may be said to be rich in public and private buildings of importance. Many of these are of a very tasteful character, and certainly reflect great credit on the spirit of the inhabitants. The main portion of the edifice before us, being that shown on the plan, is entirely faced with tooled Ashlar, from the quarries of Saddleworth, in Lancashire, and the remainder of the building faced throughout, with stone from the neighbourhood, neatly hammer-dressed.

Ground Plan.



Scale 30 feet to an inch.

A, Area. P, Piazza, 33·0 × 8·6. E H, Entrance Hall, 33·0 × 31·0. S, part of Staircase. C R, Committee Rooms, 26·0 × 24·0. C O, Collector's Office, 13·0 × 24·0. W R, Waiting Room, 24·6 × 13·0.

The plan will describe the principal floor, which is 16 feet high in the clear, and comprises an entrance hall, approached by a *piazza* in front, and arranged as a triple colonnade of the Ionic order. A handsome geometrical stone staircase, 24′×21′ leads from this to the first floor of the building, whose principal feature is a large public room extending over the entire space shown in the plan, 83 ft. in length by 40 ft. in width, and 28 feet high to the cove. The ceiling, as will be seen by the accompanying section, is divided longitudinally into a centre and two side compartments, the former of which is a segmental *cove* with double panels or *lacunars*, the upper ones being enriched with open rosettes, screening the ventilators in the roof. To afford light and give effect to these and the members of the ceiling generally, a circular or wheel window of an ornamental character is placed in each *tympanum* or plane extremity of the *cove*. The cornice and fascia round the room are entirely plain, and where the latter crosses the ceiling transversely, dividing the three compartments before mentioned, ornamental brackets or cantilevers are introduced, connecting the soffit with the opposite walls. The doors and windows of the room are finished with architraves and cornices with plain consoles. Attached to it is a suite of ante and retiring rooms. It is intended for the use of public meetings, assemblies, &c., as well as for holding petty sessions; for this latter purpose it communicates on one side by a circular stone staircase with the police office on the ground floor, and a range of stone lock-ups in the basement. All the doors in the entrance hall and staircase, have architraves and cornices in keeping with the finishings of the large room. The whole of the timbers throughout are Kyanized. This building will be erected for *less* than the sum specified in the architects' estimate.

ENGINEERING HONOURS AND REWARDS.

It seems to be an admitted fact that England is, of all countries, that in which the fewest and most trifling honorary distinctions are conferred upon men of science—a proposition in which our readers are doubtless fully prepared to express their acquiescence, as one which they have always heard uncontroverted and deplored. For this cause our men of science have complained, and the policy of our government has been called in question, for certainly all history and experience attest to us that honorary distinctions are those rewards which are most grasped at, and most fiercely contended for. It was for a perishable crown of leaves from the neighbouring trees that kings entered the lists at Olympia, and Grecian heroes exerted all their powers. It is with such feeling that the man of science looks forward to a distinction which is to herald him in society, and to be perhaps the only reward of the labours of years, and of the greatest triumphs of the mind.—The astronomer, the geologist, the mathematician, the naturalist has few golden premiums to look forward to, a scanty professorship or a death-bed pension is the limit of his hopes, and he clings the more to a recompense which is but an acknowledgment of services, for which he can obtain no pay. The system is good, and we do not wonder that our countrymen strive for its extension, we are only surprised that they should make invidious comparisons as to their native land, when a little consideration would teach them that their lot is not so much to be contemned. Napoleon gave, it is true, his counties and his baronies, his grand crosses and his stars pretty liberally—the same may be said of other governments—now we have to ascertain what our own authorities have done in this respect. M. Arago complains most truly that we did not make Watt and others peers, but both he and most others seem neither to have reflected upon the reason for this omission, nor to have noticed what really has been done. Political power is one thing, honorary distinction another, and in no country that we are aware of, although isolated instances occur, is it a recognized principle to invest scientific men with political functions, for (with exceptions of course) no class perhaps could be found less adapted for their competent exercise. The special world of the student is not the great world of the politician, it is a sphere brilliant, but inferior, having its own laws, and pursuing its own revolutions. The chemist has been educated for his laboratory, the astronomer for his watch-tower, the naturalist for his cabinet, and so also must the politician be educated for his duties, and accustomed to their performance. This certainly is one reason why in England the peerage is not to be reckoned among scientific rewards, but there is also another, which however it may arise from prejudice, is equally authorised by precedent—the peerage of England is a rank, which whether it be held by the duke or the baron, in the scale of courts is received as princely, which coequalizes with the grandeeship of Spain, and the principality of the Roman empire—a rank similar in fact to Napoleon's dukes. Now, however it ought to have been—we know that Monge, Cuvier, and the other illuminati of the empire never were created dukes, but received a lower title, and were not, except in extraordinary cases, invested with political power. The ranks which they received, in the comparative scale of French and English society, are very little more than our knighthood, if so much, for although the counts and barons of the empire were few in number, yet France so swarms with counts and barons of other kinds that they form a very squirearchy for multitude. The same may be said of the Prussian barony and councillorship of state. Admitting then that knighthood is by precedent a competent reward, we think it will be found that England has not been behind hand, but has rather gone farther by giving, as in the case of baronetcies, an honorary title of even a higher kind. If we look only at the last half century, we shall find a multitude of distinctions given which in our opinion far outbalance any exertion of other nations. The law part[illegible] so much of a political profession that we need scarcely allude to the honours which devolve upon it, extending even to the peerage, in which it has founded so many great houses. Medicine is scarcely less cared for, as in one shape or another it has scarcely less at the present moment than a score of Sirs, many of them baronets, and since the commencement of the present century it has numbered more nearly half a hundred than any lower number. The artists come next in number, their president is always knighted, and their several departments of painting, sculpture, architecture and engraving have nothing to complain of, having half a score knighthoods among them, six in the Royal Academy. We will now skim over some of the other classes which at different times in the last fifty years have been noticed, and of course in such a list, we must be guilty of many omissions. We find of astronomers and philosophers Sir Joseph Banks, Bart., G.C.B. and Privy Councillor, Sir W. Herschel, Sir John Herschel, Bart., Sir James Hall, Bart., Sir David Brewster, Sir John Robison, &c.; of chemists, Sir Humphry Davy, Bart.; of naturalists, Sir James Edward Smith, Sir William Jackson Hooker, &c.; of agriculturists, Sir John Sinclair, Bart.; of musicians, Sir George Smart, Sir John Stevenson, &c. Antiquaries have as heralds and keepers of records political opportunities of promotion, and accordingly come off pretty well, they number Sir Wm. Woods, Sir W. Betham, Sir Harris Nicolas, Sir Nicolas Carlisle, Sir Henry Ellis, Sir Gardner Wilkinson, &c. Travellers and discovers also have a similar relation, and boast their Sir Edward Parry, C.B., Sir John Franklin, C.B., Sir John Ross, C.B., Sir Alexander Burnes, Sir James Alexander, &c. Literary men have not been so lucky, Sir Walter Scott's baronetcy being their principal.

We think we have thus run over a list which will satisfy any reasonable man that affairs are not so badly off in old England, and that in the country where William Cobbett rose from the *impasse* of the army to share in the legislation of the greatest empire of the world, that there is something to be looked forward to by every man who has talents to do good and diligence to exert them.

We have thus defended our authorities from the general charge of neglecting scientific rewards, but we cannot so easily acquit them of indifference towards a profession which has the fairest claim upon their attention. The military engineers come in with the rest of the army, the naval engineers have had their Sir Robert Seppings, and Sir Edward Symonds, but the civil engineers have received only one knighthood, and that too conferred for what was considered an architectural labour. We think that the profession has just ground to complain of this, they are rising in public estimation, possess good general rank, have performed most important public services, and yet have been passed over as to the most coveted reward. The Institute has received a royal charter, engineering is a recognized educational faculty, for which a regius professorship has been founded, honorary degrees have been conferred upon its members, and the president has received a seat in the senate of the great university of the empire, so that certainly as far as qualification goes, there is not the least ground for this holding back of favour. Two years ago we had to complain of this, and we are sorry to renew our murmurs now. In other professions there are certain defined offices, the holders of which generally receive honours, and we do not see why it should not be so with the engineers. The Presidents of the Royal Society have had a baronetcy, as also the President of the Royal Society of Edinburgh, the President of the Linnæan Society, and the President of the Royal Academy knighthood. The government lawyers, medical men, painters, sculptors, architects, musicians, heralds, naval engineers, &c., both in England and Ireland are generally knighted, so that so far from a precedent being wanted, an omission only seems necessary to be supplied. If we look at our triumphant progress in railways, bridges, steam navigation, &c., in which we are almost without rivals, we think that there can be no difficulty in selecting such of the authors of them as are fully deserving of any honour the government can bestow. We think the President of the Institute, and the government engineer both in England and Ireland should always be knighted, and we think the same honour should be conferred on the most distinguished railway and marine engineers.

James Watt has had more public statues erected to him than the Duke of Wellington. The nation has expressed its opinion, let its representatives confirm it.

A Cornish engine has been recently erected on the New Southwark Water Works, in the Battersea Fields, by Mr. W. West, and manufactured by Messrs. Harvey & Co., of Hayle Foundry, on the same principle as that erected by those gentlemen on the East London Water Works, at Old Ford, and described in the Journal. Her cylinder is 64 inch diameter, length of stroke 10½ ft. in the cylinder, and 10 ft. in the pump, working a 32 inch plunger pole, with the patent valves by Messrs. Harvey & West, which are so constructed, and the operation so easy, that it would be difficult to persuade a common observer of the existence of a valve therein.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXIII.

> "I must have liberty
> Withal, as large a charter as the winds,
> To blow on whom I please."

I. Speaking of Versailles, Theodore Hook says: "as to its extent, its galleries, its saloons and all that sort of thing, it is internally striking; but any thing more hideously frightful as a building—speaking of it architecturally—never was seen. The front, as you approach it from Paris, is indescribably mean. The garden front is bald and graceless—the associations connected with it, and the splendour of its internal decorations may and do give it a palatial character: but it is an exceedingly ugly affair." This criticism is not at all too severe, for the exterior is in fact the very maximum of littleness,—so far miraculous as it shows that it is possible to contrive a building of great extent and enormous cost that shall nevertheless be altogether destitute of effect, and possess no more grandeur—that is, artistical grandeur and dignity, than a huge barrack of the same size. So far Versailles well deserves to be styled—as it has been before now, one of the *wonders* of the world.

II. Among the qualifications usually insisted upon as requisite to an architect—of some of which, by the by, the necessity is not very apparent—we do not find enumerated the one which of all others would seem to be the most indispensable, that is, when we come to something more than mere building and construction, and consider architecture as a fine art. The qualification thus *accidentally* overlooked, as if it were the least important of any,—something which it is very well to possess, but which an architect can contrive to make shift without, is what for want of a definite term in our own language to express it, we must call "*Kunstsinn*," which word implies a good deal more than our English "*Taste*." It would seem that this and this alone distinguishes the architect from the builder—taking those names not in their professional and technical meaning, but in the sense of artist, and non-artist, or at best artist at second hand, a mere plodder who stands in the same degree of relationship to the other that a mechanical rhymer, a scribbler of Album verses does to a true poet, *cui mens divinior*. Heaven knows! it is not every one who confidently writes himself architect, that has legitimate pretensions, or indeed, any pretensions at all to such title, if it is to be taken in its nobler meaning. Which being the case, it is by no means very difficult to understand why so many of them affect to hold artistical talent in their profession so very cheap, treating it as something of an altogether secondary consideration. Nothing is more common than to hear such people exclaim "O! that is all mere matter of taste and opinion." Most true, yet it is not every one who can distinguish between good and bad taste,—much less who is able to display superior taste in his own productions. It is true, taste is not absolutely indispensable on every occasion: nevertheless it is of paramount importance in edifices laying claim to be considered works of fine art, for in such case wanting æsthetic value, they want what, in that character is most essential to them. So far therefore, there is a very material difference between being a most excellent builder and an accomplished architect—and master of the art: not that excellence in construction is no merit in itself, or one that may be dispensed with at pleasure, but it is one which is negative as far as the æsthetic value of an edifice is concerned. Health and strength of body do not constitute beauty: in themselves, indeed, they are more essential requisites, but still they are distinct qualities from the other, although they, to a certain extent, contribute to it. In like manner does good building—able construction contribute to the value of an architectural production, but it cannot be received as an equivalent for æsthetic beauty, where this latter exists not, or perhaps, is most obviously and offensively deficient. This distinction between the Useful—the Necessary, and the Beautiful ought never to be lost sight of: least of all in these our mechanical, engineering times, when they are apt to be confounded together; and when it not unfrequently happens that mere utility and economy alone are considered all in all, and all-sufficient; and taste to be something which it is as well to have as not, provided it comes of itself, and can be had without trouble, but which is not worth any study or pains to secure it.

III. Architects are somewhat unjust and inconsistent in depreciating a class of artists whom they themselves have called into existence, namely, those styling themselves Decorators; for the latter would certainly not possess the control they now do, were it not that the others have, in a manner, surrendered up to them one entire and certainly very important province of their own art,—that one, in fact, where alone there is room for the display of aught like taste or invention in domestic architecture generally. On this last account, it might be thought that instead of neglecting—we might say abandoning, that particular department of architectural design, the profession would apply themselves to it more especially, as affording the majority of them almost the only opportunities they can hope for, of displaying any ability as artists. So very far, however, is it from being the case that, on the contrary, all relating to the interior arrangement and decoration of private houses, seems to be quite overlooked in an architect's professional studies, and treated as if scarcely belonging to them. Very rarely indeed is any subject whatever of the kind to be met with at any of the exhibitions at the Academy; while even those who publish designs expressly purporting to be studies of domestic architecture, and to furnish ideas for those who intend to build, are equally shy of submitting any examples of interior fitting up and embellishment, confining their attention, as far as interior is concerned, merely to adjustment of the plan; and again in regard to this last, satisfying themselves with doing no more than consulting ordinary convenience, and avoiding palpable defects; but without aiming at any thing further—at any kind of effect, either as regards the general distribution or the individual rooms. The consequence is that when the architect has completed his task, and taken his leave, the owner finds all in the rooms in his house—with the exception perhaps of vestibule and corridors—quite in an unfinished state—with bare, blank walls. Of course then the decorator—who perhaps may be no better than a mere paperhanger—must be called in, to give the finishing touches to the rooms, before the upholsterer comes in his turn, with his readymade taste:—and it is well if between decorator and upholsterer, the architecture—that is, supposing there to be any at all —is not fairly smothered. Architects—at least ninety-nine out of a hundred, will say that such finical matters as those of mere fitting up and ornament, do not at all belong to them, nor have formed any part of their studies. The consequence is that the whole department of taste in regard to such matters, is consigned over to a class of persons who have generally but a very poor stock of that article, and with whom what is most expensive of its kind, and the newest in its fashion, is always sure to be the tip-top of elegance.

ON THE STATE OF THE ARTS IN ITALY.

Brief Observations on the State of the Arts in Italy, with a short account of Cameo-cutting, Mosaic work, Pietra Dura, and also of some of the Domestic Arts and Mechanical Contrivances of the Italians. By Charles H. Wilson, Esq., Architect, Edinburgh, A.R.S.A., and M.S.A. *Read before the Society of Arts in Edinburgh, Nov. 1840, and printed in the Edinburgh New Philosophical Journal, for January 1841.*

I feel that I ought to apologise to the Society for bringing before it a paper of this nature, which contains no description of any new art or discovery, but which may rather be described as being little more than a *catalogue* of arts and practices, most of which are of great antiquity. I hope that such a paper may be deemed admissible. As far as my individual opinion goes, I would say that it would be very desirable if several papers were read every session containing as distinct accounts as could be obtained of the state of the arts and sciences, with reviews of the progress made in them in different Continental countries every year. That such papers would be useful in various points of view appears to me sufficiently obvious; those who have neither leisure nor opportunity to inquire for themselves would by this means obtain a great deal of valuable and interesting information; our efforts to excel in the arts and sciences would be stimulated; and, above all, I think that, whilst our national vanity would be advantageously chastened, feelings of respect and esteem, founded on a knowledge and just appreciation of the merits of other nations, would beyond all other influences lead to international amity. Feelings like these have already been happily nourished by the amicable intercourse of literati of different nations: the course which I advocate would tend to the further diffusion of such sentiments amongst all classes.

I cannot, without presumption, imagine for a moment that the paper which I now bring before you can deserve to be considered one of such a series. I went abroad at a very early age, and my time was entirely given up to the study of the art to which I had devoted myself, and which every thing around me tended to increase my love of. The collateral studies of the youthful artist are naturally those connected with his art, and are greatly more extensive in Italy, from many favourable circumstances, than in Scotland, and the brief allusion which I have made to them and to the time of life when I lived abroad, is meant as an apology for the meagreness of the details which I humbly bring under you notice.

Any comment on the political condition of Italy would be out of place in a paper to be read here, although a distinct apprehension of it would be necessary previously to any inquiry into the state of her arts and sciences, and also to enable us justly to appreciate the great merits of Italian philosophers and literati, who, despite of adverse circumstances, so greatly distinguish themselves; but to so slight a sketch of the *arts* of Italy as that I am about to offer, any lengthened observations are not so necessary. Whatever may be our opinion of Austrian principles of government, and of Austrian influence in Italy, all who have visited the Italian territories of that power, must, I think, acknowledge that Lombardy is greatly in advance of the independent states, and in no part of Europe, Scotland excepted, are there more numerous schools for the instruction of all classes of the people. As the traveller advances southward, with nominal independence political degradation increases, and the general character of the people is lowered. We can feel no other emotions than those of regret for the prostration of Italy; but if we examine into the customs of the Italians, we shall every where find expressive indications of ancient power and refinement, and pleasing proof that, where civilization and its attendant sciences and arts has once held extensive sway, advantages are secured of which it is almost impossible, or at any rate very difficult, to deprive a people.

I shall commence with a brief notice of the art of painting in Italy: this fine art has gradually declined, and there seems to be no indication at present of its recovery. It is trammelled by academic system. The Roman school is distinguished by a cold affectation of classic purity, and a want of energy and nature in all its productions; but, whilst we avoid the errors into which it has fallen, we should not allow these, and the difference of its practice from our own, to blind us to its good qualities; many Roman artists draw exceedingly well, and they evince this power in the large and fine cartoons which they are in the habit of executing before commencing a picture. But if the student in this country does not draw long enough, which I think is the case, the Italian student, in acquiring his mastery of the crayon, seems to forget that he is ever to use the brush; and the Italian artists rarely prove even tolerable colourists, whilst their prejudices as to the adoption of many necessary processes in painting, and which were unquestionably in use amongst their great predecessors, are invincible. This was illustrated in an amusing manner one day in the Florence gallery. An Italian artist was busy copying a Venetian picture, and my late friend Mr. James Irvine, happening to look at his work, remarked to him that he never could hope to imitate the brilliancy of the original without glazing. "I know that," said the Italian, "but I won't glaze."

At Florence, painting is in much the same state as at Rome; of late some artists have endeavoured to add richness in colour to the correctness of their drawing, but they have only succeeded in arranging on their pictures in brilliant juxtaposition rainbow colours, without attaining that harmonious effect which marks the works of their great predecessors. At Naples, painting is at a low ebb; at Genoa, lower still; at Venice, it is little better; but at Milan it reckons amongst its professors clever men in some departments of the art.

Fresco painting is still pursued in Italy, but with most success by the Germans. I wish to avail myself of this occasion to do homage to the extraordinary merits of the masters of this distinguished school; in looking on their works, we cannot but regret that greater encouragement is not given to the highest department of painting in this country; in those which are encouraged, our artists excel; and we may, I think, therefore, justly conclude that ability would soon be found to execute works of the noblest description.

Engraving may appropriately be considered after painting. You are all, doubtless, well acquainted with the great names which have lately marked the progress of this art in Italy; most of these distinguished artists are now dead. Several of Raphael Morghen's pupils are much esteemed, the best of whom are established at Milan; many very fine and important works have been lately finished or are now in progress. Messrs. Ludwig Gruner and Rusweigh, both Italianized Germans, promise to revive the style of Marc Antonio with success.

The Italian engravers are most successful in their works from historical pictures; but a practice which they follow is, in my opinion, calculated to prevent their imitating with fidelity the style and feeling of the artist whose production they copy. They engrave from highly finished chalk drawings copied from pictures by artists who devote themselves to this branch: however faithfully these may apparently copy, it is certain that their drawings will, to a certain extent, exhibit their peculiarities of mind and feeling, and, as the engraving must likewise so far be marked by the style of its author, the process is not favourable to the production of engravings of a faithful character.

It is but fair to mention that this practice is forced upon the Italian engraver, as he can neither transport gallery pictures nor frescoes to his study.

The landscape engravings of Italy are not successful. Frigid imitators of Woollet in general, their works are far inferior to those of that admirable master.

Sculpture is certainly the art which stands highest in Italy. Canova rescued it from the infamy into which it had sunk, and his genius at once raised it to excellence. If I say that that immortal artist has worthy successors amongst his countrymen, I express, as strongly as possible, a favourable opinion of the state of the art. If we are to term that the Roman school of sculpture which reckons amongst its professors all the great sculptors of various nations who make the Eternal City their fixed place of residence, then we must, I think, hold that it is the first school existing. England is worthily represented in that united school. I shall not venture upon any comparison between it and our present British school: but it is an important fact, and to its honour, that, before Canova resuscitated sculpture in Italy, England could boast a succession of very eminent sculptors. I may mention the estimation in which our great Flaxman is held in Italy. "Flaxman," said a distinguished artist to me on one occasion, "was the greatest sculptor the world has known since the time of the Greeks;" and this opinion is very general in Italy. I touched shortly on the state of painting in the different Italian capitals. I shall pursue the same course with sculpture, but more briefly still, merely remarking that, with one or two exceptions, there are no Italian sculptors of eminence out of Rome.

In connection with the arts of painting and sculpture, we may now consider mosaic work and cameo-cutting as practised in Rome. The art of mosaic work has been known in Rome since the days of the republic. The severe rulers of that period forbade the introduction of foreign marbles, and the republican mosaics are all in black and white. Under the empire the art was greatly improved, and not merely by the introduction of marbles of various colours, but by the invention of artificial stones, termed by the Italians *smalti*, which can be made of every variety of tint.

This art was never entirely lost. On the introduction of pictures into Christian temples, they were first made of mosaic: remaining specimens of these are rude, but profoundly interesting in a historical point of view. When art was restored in Italy, mosaic also was improved, but it attained its greatest perfection in the last and present century. Roman mosaic, as now practised, may be described as being the production of pictures by connecting together numerous minute pieces of coloured marble or artificial stones: these are attached to a ground of copper by means of a strong cement of gum mastic, and other materials, and are afterwards ground and polished as a stone would be to a perfectly level surface: by this art not only are ornaments made on a small scale, but pictures of the largest size are copied. In former times the largest cupolas of churches, and not unfrequently the entire walls, were encrusted with mosaic. The most remarkable modern works are the copies which have been executed of some of the most important works of the great masters for the altars in St. Peter's. These are in every respect perfect imitations of the originals; and when the originals, in spite of every care, must change and perish, these mosaics will still convey to distant ages a perfect idea of the triumphs of art achieved in the fifteenth century. The government manufactory in Rome occupies the apartments in the Vatican which were used as offices of the Inquisition. No copies are now made, but cases of *smalti* are shown, containing, it is said, 18,000 different tints. Twenty years were employed in making one of the copies I have mentioned. The pieces of mosaic vary in size from an eighth to a sixteenth of an inch, and eleven men were employed for that time on each picture.

A great improvement was introduced into the art in 1775 by the Signor Raffaelli, who thought of preparing the *smalti* in what may be termed fine threads. The pastes or *smalti* are manufactured at Venice in the shape of crayons, or like sticks of sealing-wax, and are afterwards drawn out by the workman at a blow-pipe, into the thickness he requires, often almost to a hair, and now seldom thicker than the finest grass stalk. For tables and large articles, of course, the pieces are thicker; but the beauty of the workmanship, the soft gradation of the tints, and the cost, depend upon the minuteness of the pieces, and the skill displayed by the artist. A ruin, a group of flowers or figures, will employ a good artist about two months when only two inches square, and a specimen of such a description costs from 5*l.* to 20*l.*, according to the execution; a landscape, six inches by four, would require eighteen months, and would cost from forty to fifty pounds. This will strike you as no adequate remuneration for the time bestowed. The finest ornaments for a lady, consisting of necklace, ear-rings, and brooch, cost forty pounds. For a picture of Paestum, eight feet long, and twenty inches broad, on which four men were engaged for three years, 1,000*l.* sterling was asked.

I shall now notice the mosaic work of Florence, before touching on cameo-cutting. It differs entirely from Roman mosaic, being composed of stones inserted in comparatively large masses: it is called work in *pietra dura*. The stones used are all more or less of a rare and precious nature. In old specimens the most beautiful works are those in which the designs are of an arabesque character. The most remarkable specimen of this description of pietra dura is an octagonal table in the *Gabinetto di Baroccio*, in the Florence Gallery. It is valued at 20,000*l.* sterling, and was commenced in 1623 by Jacopo Dutelli, from designs by Ligozzi. Twenty-two artists worked upon it without interruption till it was terminated in the year 1649. Attempts at landscapes, and the imitation of natural objects, were usually failures in former times, mere works of labour, which did not attain their object; but of late works have been produced in this art, in which are represented groups of flowers and fruit, vases, musical instruments, and other compatible objects, with a truth and beauty which excite the utmost admiration and surprise. These pictures in stone are, however, enormously expensive, and can only be seen in the palaces of the great. Two tables in the Palazzo Pitti are valued at 7,000*l.*, and this price is by no means excessive. These are of modern design, on a ground of porphyry, and ten men were employed for four years on one of them, and a spot is pointed out, not more than three inches square, on which a man had worked for ten months. But Florentine mosaic, like that of Rome, is not merely used for cabinets, tables, or other ornamental articles: the walls of the spacious chapel which is used as the burial-place of the reigning family at Florence are lined with pietra dura, realizing the gem-encrusted halls of the Arabian tales. Roman mosaic, as we have seen, is of great value as an ally to art: but Florentine mosaic can have no such pretensions, and time and money might be better bestowed. The effect is far from pleasing in the chapel I have alluded to, and I think that the art might be advantageously confined to the production of small ornaments, for which it is eminently adapted.

An imitation of the pietra dura is now made to a great extent in Derbyshire, where the Duke of Devonshire's black marble, said to be quite equal to the famous Nero Antico, is inlaid with malachite, Derbyshire spars, and other stones: but the inlaying is only by veneers, and not done in the solid as at Florence. This, with the softness of the materials, makes the Derbyshire work much cheaper, and yet for a table, twenty to twenty-four inches in diameter, thirty guineas is asked. Were a little more taste in design and skill in execution shewn, the Derbyshire work might deserve to be more valued, as the materials, especially the black marble, are beautiful.

I shall now return to cameo-cutting. This art is also of great antiquity, and is pursued with most success in Rome, where there are several very eminent artists now living. Cameos are of two descriptions, those cut in stone, or *pietra dura*, and those cut in shell. Of the first, the value depends on the stone, as well as in the excellence of the work. The stones most prized now are the oriental onyx and the sardonyx, the former black and white in parallel layers, the latter cornelian, brown and white: and when stones of four or five layers of distinct shades or colours can be procured, the value is proportionably raised, provided always that the layers be so thin as to be manageable in cutting the cameo so as to make the various parts harmonize. For example, in a head of Minerva, if well wrought out of a stone of four shades, the ground should be dark grey, the face light, the bust and helmet black, and the crest over the helmet brownish or grey. Next to such varieties of shades and layers, those stones are valuable in which two layers occur of black and white of regular breadth. Except on such oriental stones no good artist will now bestow his time: but, till the beginning of this century, less attention was bestowed on materials, so that beautiful middle-age and modern cameos may be found on German agates, whose colours are generally only two shades of grey, or a cream and a milk-white, and these not unfrequently cloudy. The best artist in Rome in *pietra dura* is the Signor Girometti, who has executed eight cameos of various sizes, from 1½ to 3½ inches in diameter, on picked stones of several layers, the subjects being from the antique. These form a set of specimens, for which he asks 3,000*l.* sterling. A single cameo of good brooch size, and of two colours, costs 22*l.* Portraits in stone by those excellent artists Diez and Saulini may be had for 10*l.* These cameos are all wrought by a lathe with pointed instruments of steel, and by means of diamond dust.

Shell cameos are cut from large shells found on the African and Brazilian coasts, and generally show only two layers, the ground being either a pale coffee-colour or a deep reddish-orange: the latter is most prized. The subject is cut with little steel chisels out of the white portion of the shell. A fine shell is worth a guinea in Rome. Copies from the antique, original designs, and portraits, are executed in the most exquisite style of finish, and perfect in contour and taste, and it may be said that the Roman artists have attained perfection in this beautiful art. Good shell cameos may be had at from 1s. to 5s. for heads, 3s. to 1l. for the finest large brooches, a comb costs 10l., and a complete set of necklace, ear-rings, and brooch cost 21l. A portrait can be executed for 4l. or 5l., according to workmanship.

Having now touched upon those minor arts which have an intimate connection with painting and sculpture, I shall make a few observations on architecture, and the constructive and decorative arts which are connected with that science, but this I must do very briefly indeed, as otherwise I should occupy too much of the time of the Society.

The architects of Italy have but little scope for a display of ability, as the population is not on the increase, but, on the contrary, except in parts of the Austrian States, has shrunk away from the number required to occupy the palaces, villas, and houses which already exist both in town and country; and this is painfully proved by the number of empty and dilapidated edifices. The various buildings which belong to Government, the churches, colleges, and hospitals, have generally been built on a scale of magnificence which has never been excelled, in some instances never equalled, in other countries, but all betoken more or less the same melancholy decline. By this observation I do not mean to convey the idea that the buildings themselves are ruined or neglected; I allude to their emptiness, and to the absence of that state which once filled them with its splendour. To her honour, the hospitals of Italy have long been known for their number, extent, and order, and these are still models in many respects. Although not *many* works, yet some of great magnitude are going on in Italy, and in these taste in design, magnificence in material, and solidity of construction, are displayed. The restoration of the Basilica of St. Paul's at Rome is an immense undertaking: to effect it, contributions have been obtained from all countries, whether in money or materials. It is said that George the Fourth subscribed: and I may mention that the façade of another church in the Eternal City has been built at that sovereign's expense, in a way which he must little have anticipated. When the celebrated Gonsalvi visited England, his Majesty presented him with a magnificent snuff-box, which the cardinal in his will directed to be sold, and the proceeds applied to put a front on a church which had for a long time been unfinished in that respect.

The passion which all pontiffs have displayed for building still animates the less potent holders of St. Peter's chair of our day: and although inhabiting a palace which contains twenty-two court-yards, twelve halls of entrance, twenty-two grand stair-cases, and thirteen hundred of various descriptions; two large chapels, and eleven thousand rooms and galleries, in which miles may be walked without returning on the steps, yet each succeeding pope adds or alters, or marks repairs with his sculptured coat of arms.

Although there is not much employment for architects in Italy, there can be no question of the skill displayed in erecting their designs. The masonry is excellent, and the ancient Roman brick-work is rivalled by that of the present generation: houses are built of brick, in which all the exterior decorations are moulded in that material as perfectly as if executed in stone. The skill with which the Italian workmen build in brick may be exemplified by a notice of the Florentine practice of arching over rooms without centering of any description. Two thin moulds of board, the shape of the intended arch, alone are used; these are placed at each end of the apartment which it is intended to cover in, and pieces of string are stretched from the one to the other, guiding the workman as he advances in the formation of his arch, which he builds, uniting the bricks by their thin edges (greatly thinner than in those we use), and trusting entirely to the tenacity and quick setting of the cement.

Plastering is carried to a perfection in Italy of which we have, I believe, no idea in this country; rooms are so exquisitely finished, that no additional work in the shape of house-painting is required, the polish of the plaster and its evenness of tint rivalling fine porcelain. At times the surface of the plaster is fluted, or various designs are executed in *intaglio* upon it, in the most beautiful manner. Scagliola, a very fine preparation from gypsum, is the material chiefly used.

As an instance of the cheap rate at which this work is done, I may mention the new ball-room in the Palazzo Pitti, grand-ducal residence at Florence, which, including mouldings, figures, bas-reliefs, and ornaments, was executed at a cost of two crowns for every four feet square.

Work in scagliola naturally follows in my notice of the arts of architectural decoration; but this I need not decribe, as the art is now practised in England with great success, and an artist has lately settled in Edinburgh, whom I earnestly hope may meet with encouragement. A most beautiful art may be mentioned here in connection with the last, I mean that of making what are termed Venetian pavements which might advantageously be introduced into this country. The floors of rooms are finished with this pavement, as it is somewhat incongruously termed, and I shall briefly decribe the mode of operation in making these, but must first observe that they are usually formed over vaults. In the first place, a foundation is laid of lime mixed with *pozzolana* and small pieces of broken stone: this is in fact a sort of concrete, which must be well beaten and levelled. When this is perfectly dry, a fine paste, as it is termed by the Italians, must be made of lime, *pozzolana*, and sand: a yellow sand is used which tinges the mixture: this is carefully spread to a depth of one or two inches, according to circumstances. Over this is laid a layer of irregularly broken minute pieces of marble of different colours, and if it is wished, these can be arranged in patterns. After the paste is completely covered with pieces of marble, men proceed to beat the floor with large and heavy tools made for the purpose: when the whole has been beaten into a compact mass, the paste appearing above the pieces of marble, it is left to harden. It is then rubbed smooth with fine grained stones, and is finally brought to a high polish with emery powder, marble-dust, and, lastly, boiled oil rubbed on with flannel.

This makes a durable and very beautiful floor, which in this country would be well adapted for halls, conservatories, and other buildings. In connection with the arts which the architect summons to his aid, I shall now notice that of ornamental sculpture: and here again we must acknowledge the superior skill of the Italians. The chief encouragement to artists of this description, is that given by foreigners, especially by English travellers in Italy. Copies of ancient sculptures, vases, chimney-pieces, and other ornamental articles, are executed in the most perfect manner, and at a very cheap rate. Such is the skill of the Italian workmen, that a native of Carrara actually cut a bird-cage in marble, which he presented to his sovereign the Duke of Modena, who, by the return he made, rather showed his sense of the folly of the sculptor, than of his patient perseverance in the production of so useless a specimen of his skill.

But whilst the sculptor displays his skill in these comparatively trifling departments, he is equally successful in the execution of architectural details on the most gigantic scale, whether in solid marble or in veneer. By this latter art he produces magnificent columns plain and fluted, the core of which is of coarse stone, but the joining of the marble-coating is so perfect that the finished pillar seems a mass of solid marble. The marble is attached in a rough state to the core by means of a cement composed of resin and marble dust, which is so tenacious that it admits of the hammering, chiselling, and polishing necessary in finishing the work. By means of this system of veneering, the interior walls of churches and other buildings are encrusted with rich and varied marbles, and tables and other articles of furniture are manufactured at a very cheap rate. The art which I have just described is, in fact, that of pietra dura on a gigantic scale.

With the sculpture of the Italians in alabaster, you must be all acquainted. This art is chiefly practised at Pisa, Florence, and Leghorn. The material, besides being used in sculpture, is ingeniously applied in Rome to the manufacture of false pearls. The pieces of alabaster, after being turned and filed into the proper shape, are enveloped in a brilliant paste, made with the scales of a very small fish found near the shores of the Mediterranean.

To return to the subsidiary arts of architecture, I may remark that the carpentry of the Italians, as observable in ordinary houses, displays little skill and indifferent workmanship; but in the roofs and floors of important buildings, they satisfactorily prove their knowledge of scientific principles, and several of their designs are well known to British architects.

With regard to the working of iron, in comparison with our system the Italian is primitive indeed; yet at times they can and do produce very good specimens of workmanship, but at a heavy cost; consequently they are generally content with very ordinary productions. A manufactory of wire, and of driving and screw nails, by means of machinery, *now occupies the villa of Mecænas at Tivoli;* the articles produced are very well made. Copper is extensively used in Italy, and there are productive mines in the *Maremma Toscana*. The workmanship of articles made of this metal is respectable; various utensils are made of brass in a very neat and satisfactory manner, but in the interior finishing of houses, if much nicety is required, articles of foreign manufacture are used.

House-painters may be mentioned in the last place, and these display much taste and skill; and there is a class of them who greatly excel those in this country, having more the feeling and taste of artists. Surrounded by the finest models in this art, the Italian decorator enjoys every advantage in its study, and he inherits besides from the best periods of art, or rather from all antiquity, taste and a good system of workmanship. He is not a mere machine like the workman in this country, who has little use for an intellect beyond enabling him to use his moulds, stamps, and the various mechanical contrivances which confine all our decorative arts within such commonplace limits.

In all our architectural drawings and engravings, we find a vigorous artist-like style, which is reflected in the works done from them. In the architectural engravings of the present day, every thing is sacrificed to a display of dexterity in the use of the burin; the spirit of the original ornaments is never represented. How strongly this is illustrated, for example, in our engravings from Etruscan vases! Works executed from such engravings, or from drawings like them, are naturally stiff and lifeless like the models. People who possess a feeling of taste, dissatisfied with such productions, seek to replace them with older specimens, and amongst other things very inconvenient carved chairs and tables, in the workmanship of which they find a pleasure in tracing the influence of mind. But the cleverness in the workmanship of these specimens has greatly misled the taste of the day; and the abominations of Elizabethan architecture, lately dignified with the name of the *Renaissance* style, of which however it is a mere caricature, the extravagances of the Louis XIV. and XV. eras, or the debonnaire barbarisms of Watteau, have contributed to the banishment of a healthy taste in style. To restore a feeling for better art, the purer styles of classic or Gothic art must again be executed in the spirit of better times, and to grace of form must be added feeling in execution.

I shall now turn to the engineering works of Italy, a subject worthy of much attention, but on which I regret to say I am able to say very little indeed. The greatest works I saw going on were those at Tivoli, and from the Ombrone to the Lake of Castiglione in the Tuscan Maremma. I shall merely offer a very brief description of these works, necessarily very imperfect, as I write entirely from memory. The Tiber or Aniene, on reaching Tivoli, was dammed up by the architect Bernini: precipitating itself over the lofty barrier he raised, it disappeared under the rocks on which the town is built, and was seen again in the celebrated grotto of Neptune; rushing out of this remarkable cavern it fell into another abyss, and again vanished into the grotto of the Sirens, from whence it issued in the deep valley under Tivoli, several hundred feet below its original level. The pencils of the painters of every nation have been employed for centuries with this,

Fig. 1.

A, Great Fall. B, Neptune's Grotto. C, Fall. D, Fall. E, Grotto of Sirens. F, F, New Tunnels. H, New Fall. I, Road to Villa of Mecena.

I may say, terrible scenery, this *orrido bello*, of the falls of Tivoli. They may now depict the rocks, but the waters are gone for ever. Some years ago, Bernini's dam was carried away in a flood: it was rebuilt by the Pope's engineers, but if I remember aright the river got the better of them and threw down their work; at last they dammed up old Tiber, and made the very ugliest waterfall that ever unfortunate artist contemplated. It was now discovered that the river, in passing through Neptune's grotto, had worn away the rocks in such a manner that the town and its temple depended on a rugged pillar, the duration of which could not be calculated upon. To prevent the town paying a visit to the Sirens beneath, it was resolved to turn the river, and it will be acknowledged that this was a bold undertaking; walled in by mountains, it sought a passage under them: and to a certain extent imitating the operations of nature, the engineers have carried the river through two parallel tunnels, and tumbled it into the valley beyond the Sirens' grotto over a bank twice or perhaps three times as high as the Caston hill. The engineers have saved Tivoli, but its romantic beauty, as far as the river is concerned, is gone for ever.

The other engineering work which I mentioned, namely, the canal from the Ombrone to the Lake of Castiglione, has excited much interest. The Lake of Castiglione, anciently the Lacus Prilis, falling very low in summer, left much marshy ground uncovered, in which were numerous stagnant pools, and quantities of putrid herbage, making the air poisonous in hot weather, and breeding myriads of noxious insects. To remedy these evils, Leopold the First ordered his architect Ximenes to make a canal from the river Ombrone to the lake: by this means it was intended to keep the latter constantly at the same level. This work was finally executed by the present Grand Duke in the year 1830, and by means of a canal seven miles long and twenty-five feet broad, a sufficiency of water is supplied to keep the lake at a proper level; so sufficient indeed was the supply that the whole surrounding country was overflowed the first year, but this has been remedied. The air it is said has been improved; but when I visited Castiglione in 1832, I found that all who could left it in the summer months, and all who remained had the fever. Some notice may be expected from me of the engineering works in the Pontine marshes; but like other British travellers, I have only galloped through them, and have merely to state that the attempts to drain them cost a million of money.

The roads in the north of Italy are excellent, and indeed generally throughout the Peninsula; although a small portion comparatively of the country is intersected by roads; and I have travelled many miles over turf, or by small mule tracks, both on the coast and in the mountains. Towns are almost universally built on eminences; consequently the roads are hilly, but I think less so than would be supposed from the nature of the country, and both in direction and in smoothness, they greatly excel those of France.

The system of road-making followed is nearly the same as that adopted by the late Mr. Telford, that is to say, a pavement of stones is first formed upon which the metal is laid; but I do not think that the principles advocated by our great engineer are followed out in the formation of the pavement. Excellent roads, however, are the result of the system, even although gravel is used instead of broken metal.*

Various principles of paving are now exciting much attention in London; it is to be regretted that something like a sensible principle is not followed in Edinburgh. In Italy various mode are adopted, in Genoa and at Naples large flat parallelograms of lava are used, at Florence large irregular polygons carefully jointed, and at Rome a pavement resembling our own, except that the stones are of irregular forms, of one size, and grouted in with lime and *pozzolana*.

I shall now touch very briefly on a few arts of Italy which remain to be described, and shall then take the liberty of bringing before you one or two contrivances which struck me as ingenious and of which I have prepared drawings.

The goldsmiths of Italy produce ornaments which are both remarkable for taste and workmanship, especially those of Genoa and Venice. I am enabled to show you some trifling specimens which our workmen cannot equal.

After the goldsmiths I may mention the makers of bronze ornaments and figures; this is an art in which the Italians show much taste and dexterity, so much dexterity indeed that they sell numbers of antique

* I have not seen the railroad which has been lately made from Naples to Castellamare, but am well acquainted with the line; a novel question in engineering must arise in considering how it is to be protected from the lava of Vesuvius. This I believe will not be very difficult, but it has a more insidious enemy in the earthquake, and a more overwhelming one in the showers of scoriæ and ashes which accompany an eruption.

Railways may be useful in Italy to promote her commercial prosperity, but I pity the man who could think of travelling in such a manner through any part of that country.

bronzes of modern fabric yearly to *soi-disant* antiquaries, who, however, neither possess that extensive learning nor profound experience and correct taste necessary to constitute such a character. It is much the practice in Rome to take moulds from real lizards and to cast them in bronze; these make very pretty ornaments for the table. I regret that I am unable to give you an idea of the value set upon these works.

The manufacture of glass is pursued with great success in Venice: the numerous glass ornaments for ladies which come thence are well known, and the endless varieties of form and combinations of colour given to glass beads for rosaries and embroidery, or vessels for domestic use, are very ingenious and beautiful. The ruby glass of the 1500 and 1600 can now be imitated so as to make imposition a famous trade, the false being only distinguishable by weight. Glasses are also made in which white threadlike lines of arsenic are incorporated. The process by which they make sheet-glass differs from ours. Instead of being formed into immense circular sheets, the Venetian workman blows cylinders of considerable length and diameter; he then cuts off the two ends of his cylinder, dexterously slits it down one side, and spreads it flat on a table in an oven. By this process sheets of a sufficient size are made, and there is no loss as in those fabricated in this country.

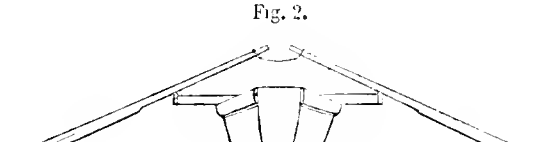
I think that I have lately observed that the process which I have thus briefly described is practised at some manufactory in England.

The velvets of Genoa, and the exquisitely turned ware of the same place, the straw hats of Tuscany, the silks of Florence, the embroideries of Rome, the musical instruments and musical strings, and although last not least, the maccaroni, of Naples, are all samples of skill creditable to the Italians.

I shall now request your attention to this lithograph of a triumphal arch. This is a specimen of an art in which the Italians display both taste and great ingenuity, and which seems to me deserving of notice, for although it may be deemed useless by some, yet it contributes largely to their happiness. I allude to their preparations for festivals and pageants. Without entering into any description of these, I shall content myself with exhibiting a print of a triumphal arch erected at Tivoli on the occasion of a visit from his Holiness the Pope. Erections of this description are put up in a day or two, being formed of a frame work of wood, covered with coarse canvass painted in imitation of stone. The bas-reliefs are of stucco, and the statues are formed of straw, arranged round wooden supports; casts of heads, hands, and feet are easily procured and attached. This *anima* (soul), as it is termed, is skilfully enveloped in drapery of cotton cloth, which is tastefully arranged by an artist, ond is then lightly brushed over with white-wash, which stiffens it. That a knowledge of the art displayed in erecting this arch may be useful, may I think be proved, by an allusion to the gallows-like erection under which his Majesty George IV. passed when he entered Ediuburgh.

In the summer of 1833 I made a journey from Leghorn to Rome along the coast, a *terra incognita* to most travellers, my object being to trace the Via Aurelia. At Orbetello, the last town in the Tuscan States, besides making some interesting antiquarian discoveries, I observed the boats which I am about to describe. Orbetello stands upon a peninsula, projecting into a shalluw lagoon of some extent; the boats which are used upon it, are flat-bottomed, rise considerably at the bow and stern, being lowest at midships, across which part of the vessel a beam is fastened, about four inches thick each way, and which projects about two feet six inches over each side. On each of the ends of this beam an oblong piece of plank is nailed, the longest sides being horizontal, and a stout pin rises from each of these. The oars are of considerable length in proportion of the boat, and of great breadth in the blade. The oars rest upon the pieces of board at the ends of the cross-beam, being attached to the pin by means of a piece of cord, in this last respect resembling a mode adopted in boats on our own coasts. The blade of the oar slightly overbalances the portion within the fulcrum on which it rests, the handles nearly touch each other, meeting a-midship. By this contrivance, one man can manage a pair of very powerful oars, and can drive a boat, which is apparently but ill adapted from its form for speed, with surprising rapidity through the water; can arrest its progress, or turn it with equal rapidity and certainty, and with very little exertion. The annexed engraving is a transverse view of one of the boats.

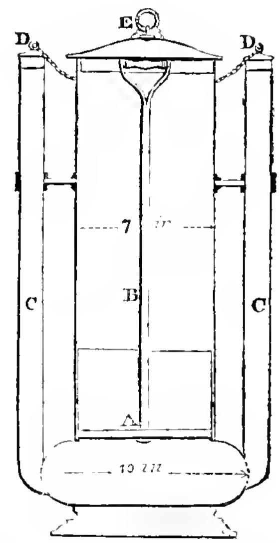
Fig. 2.



My knowledge of boats and ships is indeed very trifling, but I could not help seeing how easily the fisher of Orbetello manœuvred his rude boat; and therefore I have been induced to bring forward this notice of a vessel and mode of rowing which I am not aware has been described. Besides, it suggests ideas as to the probable mode in which the ancients managed their triremes, well worthy the attention of the antiquary, especially if he will combine the hint thus obtained with the modes of rowing followed in the Bay of Naples on board the Sorrentine boats, which, I have been led to imagine from an examination of pictures in Pompeii, are much the same in every respect as the galleys which in old times navigated the same sea.

My next drawing represents (fig. 3), by means of a section, an apparatus used in Italy for warming baths. I need not describe it, but shall merely observe generally, that it is made of copper; the live charcoal is put upon the grating A, which is put into the stove by means of the handle B, the fire is kept alive by air supplied through the tubes C C, 7 inches diameter, and when immersed in the water of a slipper-bath, this light and portable apparatus will heat it in a quarter of an hour. I think it might be useful in this country.

Fig. 3.



I now close this paper with many apologies for having detained you so long. The engineering works I have briefly described may seem trifling as compared with those extraordinary and gigantic operations you are accustomed to in this country; but I would ask you to consider the relative extent, power, and resources of the states, and you must then allow that they are very creditable to the Italian Government.

The Italians, we have seen, are still remarkable for their taste and skill in many beautiful arts, and for nearly 3000 years they have been thus distinguished. Various arts were successfully practised by the Etruscans, and when they were subdued by the ruder Romans, they did not lose their skill, but enlightened their masters.

The conquest of Greece filled Italy with artists and works of art; and when northern hordes overwhelmed the empire, these ruthless barbarians were gradually softened by the fine arts of the people they had conquered. A new power arose in Italy, and by its influence again she became pre-eminent in Europe, and we know to what illustrious perfection the fine arts again attained.

In our sale-rooms we see sold every winter many cracked and dingy daubs, and with these before him, the auctioneer rings the changes on some half-dozen names, as if the Italian school could boast no more: but a host of artists attest the fertility of Italy in the production of men of talent; and in Lanzi's dictionary, 1000 names will be found before the reader reaches the middle of the letter D in the index.

I have imperfectly described to you some of the arts which the Italian has inherited. I shall close this paper by observing that, whatever public work is undertaken in Italy—wherever improvement is contemplated, even although it should not be extensive, it is justly thought that the assistance and advice of the artist, whose taste and judgment have been cultivated, ought to be secured, and there is no practice in *its full extent* more worthy of our imitation.*

* Mr. Wilson exhibited numerous specimens of mosaic, pietra dura, cameos of different ages in pietra dura, and specimens of shell cameos; also of Genoese and Venetian jewellery, Venetian glass, and ruby glass, together with numerous prints and drawings.

ON THE STYLE OF BURLINGTON AS COMPARED WITH THAT OF PALLADIO.

Architecture and its relics betray the character of a people: an evidence in themselves of national credit or misrule, they shed a pleasing truth upon the record of history: for there is a link between the feudal castle and vassallage, between the stately palace and increasing revenue or commerce, between the more modest villa and a privileged community. Carrying our minds, then, with this pleasing idea, from the castle and the monastery, down to the 17th century, when Gothic began to yield to the influences of Italian art, we observe one architect whose talents, united to rank, justly merit our notice. Comparing him with his great master, we may, perhaps, lessen his claim to originality; but as a disciple of Palladio, he will ever appear, for the age in which he lived, an architect of refined taste and of elegant mind.

Burlington, aiming after Palladio and yet captivated by Jones, stands distinguished from both, mingling, as he does, a little from the richness of the latter, with the more grave simplicity of the former. Tamer in his conceptions, the elevation displays nothing of that intricacy of parts, or of changing features, resolved and blended into one harmonious whole as in Jones:—his unity is the whole, whilst his parts are fewer. No studied appropriation of ornament compels the eye to any particular part, no lofty feature rises to dignity. The feeling of the artist is never led astray into any redundancy—all is depressed, though carefully disposed. It cannot be said that he is grand, for that excellence is destroyed by uniformity; nor can it be said that he is mean, for his variety, though scanty, is made up of parts as much as of detail. He has his partialities, however, and loves the colonnade, through the openings of which he permits you to see his statues. Of statues, however, as of columns, he is very sparing, and seldom exhibits the former prominently except on the second story. Sufficiently alive to the sentiment of Palladio, he never wearies but always carries you pleased to the wings of the façade:—but, with here and there the introduction of a balustrade, the relief of a figure, or a special window at the wings, he is content. As an architect we must admire him more for his care than for his ingenuity, more for his adherence to the existing rules of harmony, than for that poetic sentiment, that brilliancy of idea, ever indulging though ever beautiful, displaying features ever new and yet ever subordinate.

Turning now to the Italian, let us mark his excellencies, which (being imitated by Burlington), when seen, will show how far he identified himself with the genius of his master. To say nothing of the talent which could change the features of his country's art, by investing it with charms both new and various, we might regard him merely as the vigorous restorer of ancient beauty. But, uniting the most suspicious care with the deepest enthusiasm, this master of combinations, this genius of distribution, swelled the proportions and increased the grandeur of design by a system original and true. Friendly to the pedant whilst studying at Rome, but superior to the pedant in his conceits and imaginings, Palladio allowed the same principles of rigid adjustment that guided the ancient in his proportions to assist him in his. But the contrast appears in the increased and enlarged conceptions of the latter as compared with the condensed beauties of the former, different to Burlington who seldom starts into any thing grand, or deals in gradations of feature. If the ancient has unity, expression or variety, so has Palladio. If the one has a subordination of parts so has the other:—the difference is in the extent. That correct sentiment which assisted the depressed model of antiquity, aided the giant structure of the middle ages, whilst a harmony of relation belongs to the mansions of Palladio, no less than to the temples of Rome. Burlington appears but faintly to realize these ideas of relative beauty, there is no grand feature to which others are subsidiary. In Palladio's front the giant superficies displays degrees of importance amidst its many subservient members; and it is not until the more considerable images have been scanned, that the lesser contrivances are seen. The resemblance in style between Burlington and Palladio is in the smaller auxiliaries only, where the variety is uniform, like rhymes in poetry, alternately, and where variety has its variety, "like the stanza."

It must be remembered, in conclusion, that Burlington had to follow the Italian at a great distance, and to digest a new style at a time when refinement and conceptions of the beautiful faintly existed. Remembering this, whilst looking at the monuments of taste he has left us, we see his ready talent, and that pleasing display of native genius, wanting only a closer study from the same models, and the same attention to the true elements of grandeur to have rivalled, if not to have surpassed him.

FREDERICK EAST.

REPLY TO EDER'S REMARKS ON THE ARCHITECTURE OF LIVERPOOL.

SIR.—Seeing that the remarks of "Eder," on the Architecture of Liverpool have obtained a place in your Journal, and consequently an importance which they had not when they first appeared in a paper of this town, I will, with your permission, examine them a little.

I will agree with "Eder" that the Railway Station is a great failure, but I should much like to learn from him how a front should be designed, "which by its outward appearance should tell of the great things going on behind it."

It is amusing to observe writers like "Eder" laying down dogmas such as "Every edifice should express its object. A church should display gravity and dignity, a theatre lightness and gaiety, a prison rude majesty and sturdy strength, in short every edifice should like the countenance express spirit." "In short," comes in here very well, for the writer could not furnish another illustration. What should a Bank display? a Custom House? a Market? But "Eder" has solved the latter query by telling us that the Fish Hall "presents a very quiet plain portico expressive of its object;" so then on seeing "*a very quiet plain portico*," we may rest assured of its being the entrance of a fish market! A few axioms of this kind would render guides and guide-posts unnecessary. Unfortunately, however, the proprietors do not seem to consider the portico "expressive of its object," for they have caused the words "Fish Hall" to be painted in large letters on the architrave. So great is my dullness that I never yet saw a portico which expressed its object, unless that was to keep off the rain and sun.

Eder calls the "North and South Wales Bank one of the handsomest in town," it is true that the ground is "irregular in shape," the front being a little more than a right angle, so little however as not to be worth mentioning: it is also true that the architect has been "compelled to obtain in height what he wanted in superficies, and yet here are *enormous* difficulties overcome, and a handsome building in conclusion remains." The "*enormous difficulty*" consisted in building a bank three stories in height. Now for its beauty. The front consists of a Corinthian portico *in antis*, being about three times its width in height, the columns and pilasters are crowded together, between the columns there are a door, and two tiers of windows scarcely large enough for a third rate house: the front is made about one foot narrower than was necessary to obtain less projection in the cornice of one flank, so that by this happy idea you have this foot in width sticking on what ought to have been the return of the pilaster, and decorated with the rustic work, belts, &c. of the flank, which have no connection with the front. This I confess is a "handsome" way of getting over the "enormous" difficulty of reducing the projection of the cornice. The flank which is exposed to view is a strange jumble of pilasters, paltry doors and windows of all sorts and sizes, some Greek, some circular headed, some with swelled friezes—scarcely a foot of plain masonry is to be seen here. The architect has rigidly copied the columns and entablature from an ancient example, but he has misapplied and misarranged them, and the order which charms by its lightness and grace, the spectator in the Campo Vaccino, seems here clumsy and heavy, and the substructure does not seem half strong enough to carry the entablature. The ornamental parts of the order are passably executed; all the others both in design and execution (no man *could* make those things on the principal door architrave ornamental), are most wretched. To conclude, this building has cost an enormous sum. I shall probably return to this subject, meanwhile

I remain, your's, &c.

SEYTON.

Liverpool, January 19, 1841.

Ancient Trees of the Spanish Chestnut.—Although certainly not a native of this country, England produces some exceedingly remarkable specimens of this valuable tree. In Betchwork Park, near Dorking, there are some Spanish chestnut trees of extraordinary size and great age, certainly the largest and oldest in that part of the country. There are about 80 trees, all of large dimensions. The subjoined table exhibits the circumference of some of the largest, taken about three feet from the ground:—

No. 1	17	2	No. 8	18	0
2	20	6	9	21	4
3	17	10	10	18	4
4	17	0	11	19	3
5	17	2	12	20	2
6	18	0	13	18	0
7	19	2	14	23	0

No certain record, I believe, exists of the age of these trees, but they are probably coeval with the first Betchworth Castle, founded in 1377, when "John Fitzalan, second son of Richard, Earl of Arundel, had license to embattle his manor-house here."—*Gardeners' Chronicle.*

UPON THE ARCHITECTURE OF ITALY.

A Translation of the Observations contained in the Preface to M. Percier's work, entitled "Palais et Maisons de Rome;" with some Additional Remarks upon that Preface.

By Arthur Wm. Hakewill.

The object of the following observations from the pen of M. Piercer was to induce his countrymen to bestow pains upon the smallest, as well as upon the most important works, and to anybody conversant with the French modern architecture, it must appear that the architectural productions and writings of that great architect have had their effect, France now being enlivened and beautified by numerous works upon a small scale, carefully and picturesquely designed. M. Percier was the very man to propagate principles with success; to great talent he united great amiability, and the precepts which he taught made a lasting impression, for they found their way to the minds of his pupils through their hearts, of which he had entire possession. He is now lost to France, to which country he has bequeathed a rich legacy, in the numerous skilful architectural productions and sage precepts which he has left, and the name of Percier will be long cherished, not only by a grateful country, but by all those who are sincerely devoted to the art in which he who possessed that name so greatly excelled.

It being constantly a subject of remark, that works upon a small scale in this country do not receive all that care and study so necessary to give them their full effect, it would appear that the observations alluded to might be as beneficially applied to England in the present day as they were to France formerly.

The English architect seems to think that great works alone require great exertion; it must be confessed that on such occasions he seldom fails to rise to a level with his subject, and Ste. Genevieve at Paris, compared with St. Paul's in London, either in *design* or construction, appears a toy. But it is not an occasional building of this kind that shows a nation fond of architecture, or which tends greatly to the decoration of a country; these two ends can only be compassed by the architect fairly appreciating the scope of his art, by considering it as an artificial landscape which mankind create to themselves; and therefore endeavouring to bestow on each production, however insignificant in size, all that study, care, and attention, of which the subject is susceptible, in order to produce a legitimate variety in his compositions, and to impart to each work a *correct* and *peculiar* character.

M. Percier says—

"Architects, upon their arrival at Rome, for the purpose of studying their art, will naturally bestow their first attention upon the valuable remains of antiquity, upon those imposing masses which, having resisted the ravages of time and barbarism, announce to posterity the grandeur and power of the Romans.

"After this first view, their admiration will be divided between such beautiful monuments and those which either the piety of the Popes, or the magnificence of the Roman princes, gave rise to in the fifteenth century, at the revival of the arts.

"Drawing and engraving, by multiplying the master-pieces of ancient architecture, have, as it were, laid Rome before the eyes of all; from the study of these buildings, some men of genius were enabled to deduce the elementary principles of architecture, they have taught us how to view these buildings and contrast them, whilst, by their own example, they have shown us how very possible it was to make a successful application of those fine models, upon occasions which might seem to offer but little scope for creating interest.

"This observation has, for a long time, escaped the attention of architects visiting Italy: it was thought that the studies to be made in that beautiful land, could only benefit artists who had great buildings to construct, whilst every thing which did not carry with it a certain degree of importance, was to be abandoned to the routine and caprice of workmen.

"But there are in Italy, and particularly in Rome, a vast number of charming habitations, which, under the most simple forms, bear the stamp of a refined taste, and prove to the attentive architect, that credit may be obtained in bestowing care upon the most humble production, and this reflection should be a consolation to those who profess an art, in which a very rare combination of fortunate circumstances can alone furnish the opportunity of being entrusted with the execution of great works.

"If such men as Bramante, Vignola, Palladio, Sangallo, and Peruzzi, have discovered in antiquity models for the buildings which they have erected, if these successful practitioners of the art have known how to apply, even in their slightest works, such admirable distribution, so agreeable an arrangement of parts, that refinement, *too*, which constitutes the great charm of their works, why should *we* not, when similarly circumstanced, endeavour to emulate them?

"It is with the liveliest feelings of interest that we behold the great artists whom we have just mentioned, bestowing, upon the simple habitation of the citizen, the same degree of spirit, care, and refinement of taste, which they have manifested in the erection of temples and sumptuous edifices. They have embellished every thing, and their pencils have thrown a charm over the modest retreat of the philosopher, in no way inferior to that of the palace of the prince.

"Penetrated with the importance of their art, they have taught us how to rid it of the prejudices of routine and the extravagancies of caprice, they have taught us to take nature for our guide, and her imitators for our models; and have, in some measure, restored architecture, in bringing back the art to its true intent. We ever perceive them skilfully availing themselves of the peculiarities of the site, and fulfilling, with admirable address, the various requisites of the design. Manifesting ingenuity even in the minutest detail, they never appear to have worked at random; they seem to have felt that nothing could be considered beautiful in architecture which was not authorized by some recognized utility; that true genius did not consist, as some moderns have thought, in waging war with reason to create novelties, and produce bizarre effects, but rather in the art of successfully applying the means which nature points out, which the site furnishes, and which the work in hand demands.

"It is in thus fulfilling these conditions that they have succeeded in imparting to each work its proper character, and it is thus that, ever guided by good taste, they have been enabled to make us lose sight even of the very difficulties they had to combat.

"Indeed, the greater part of their works bear the impress of that rare simplicity which, like some revealed truth, always appears so intelligible to those to whom it is disclosed.

"Their buildings are picturesque without being confused, possess symmetry but are not monotonous, and being carefully executed, frequently unite, to express ourselves in terms of art, the freedom of the sketch with the precision of the more finished performance.

"We contemplate, with unceasing admiration, the ingenuity displayed in the application of the various materials, such as marble, stone, brick, wood, &c., few examples of which are to be found elsewhere.

"It must be confessed that hitherto the Italian architects have excelled those of other nations. To produce the greatest effect with the most simple means, seems to have been the object of their ambition; whereas we, on the contrary, seem to take an opposite aim. It would appear, by the greater part of our modern works, our apartments ingeniously circumscribed, our petty distributions, our plaster columns, bronzed wood, and painted marbles, that we delighted in imitation, contenting ourselves with appearances.

"We will not seek to unveil the real causes of this degradation of the art, we cannot think that it has been brought about through motives of economy; for it would not be difficult to prove that such imitations, far from being less costly, entail, on the contrary, continual expences, both from the short time they last, as from the enormous prices set upon such works by skilful workmen.

"We might, perhaps, with regret, pronounce it to be a proof that architecture has never been held in great estimation among us; for the circumstance of a town containing a temple, a monument, a palace, is no argument that the fine arts have made it their abode; the tyranny, pride, or caprice of a single individual, may, for the moment, have chained them to the spot. But when, at every step, our attention is arrested by some masterpiece of magnificence, or even of simplicity: when in every spot we meet with monuments erected for the public good, the minutest detail characterized by that delicacy of taste which proclaims a whole nation to have been cultivators of the fine arts; then it is that we feel we are in Italy, and that that gifted land has long been their fixed abode.

"It is in that country alone that the most humble habitation offers to the attentive architect beauties, not very imposing, perhaps, in point of scale, but more immediately adapted to the wants of the community. It is to be observed that the charm of these buildings results from the arrangement of the plan and distribution of the masses, and not to a vain profusion of ornament.

"We do not pretend to say that the buildings which we have cited should be servilely copied, nor do we quote them as being entirely free from defects; we are also aware that our climate, materials, and habits, often prescribe other forms. But still we may safely assert, that by following the method which the Italian architects have pursued in their compositions, in considering them relatively to the conditions they had to fulfil; in short, *by studying them*, an attentive architect will know how to reap advantage from the light which they throw upon his art."

Thus far our author.

In the course of these observations there is one which it may be allowable to remark upon, viz., the conviction that comes over the mind of the traveller in Italy, that that favoured land has once been the fixed abode of architecture. In her flight from Greece to Italy, architecture alighted upon a congenial soil, and flourished through the land, owing to the solicitude of the inhabitants in courting her stay among them. The Italians soon found that architecture was their domain, and set about studying it in that vigorous manner in which a nation endeavours to effect any object influencing its honour; the chief requisites for an architect being ascertained, they were early inculcated, and geometry and drawing were made the basis of excellence; indeed, most of the Italian architects drew like painters; all dwell upon the importance of that art in their writings, and manifest it by the *rigour, delicacy*, and *choice of detail*, in their buildings; and one of them, Scamozzi, treats of it in terms of veneration, and says "that since, by means of drawing, that is so easily expressed which cannot be described, even by a multiplicity of words, we may rightly say that this art should be rather considered as a heavenly gift than as a mere discovery of human invention"—in the original thus:

"Di modo che, per via del disegno, si esprime molto facilmente tutto quello, che non può far la moltiplicità delle parole expresse, o descritte in carta, e per ciò, a ragione si può dire, che il disegno sia piu tosto dono celeste di Dio, che cosa ritrovata dall'ingegno humano"—

We may clearly see that it was not because architecture was practised by Italians, that the art made steady progress towards perfection, but because the Italians, appreciating the art, studied it in a legitimate manner, resting their claims upon the intrinsic merits of their compositions, and having no recourse to the blandishments of art, either to make a parade of their beauties, or to screen their defects; hence it was that buildings, promising comparatively but little upon paper, when erected became a real embellishment, creating delight and surprise, answering completely the description of a French writer, who says that a building should suit as a model to an architect, as a subject for the painter, and as an object of attraction to the general observer.

A very little reflection will make us feel that the course we pursue is very different from that pursued by the Italians of the fifteenth century, and those who once shed a lustre upon this nation during its great periods of art.

It is ever essential that the means taken should be commensurate with the end proposed; and as the end here is great, the means should be so too. Architecture is a severe art, and consequently should be severely studied. *Geometry*, the *orders*, the human form, foliage, the countless and various objects of nature, are fit subjects for the serious attention of the student of so delightful, comprehensive, and sublime an art as that of architecture. Doubtlessly, there are many accomplishments which, if not pursued to the detriment of more solid acquirements, add greatly to the perfection of the architect. But may it not be asked whether we of the present day pay not too much attention to these accomplishments, viewing them rather as the fit materials for the foundation of our studies, than as what they should be considered, the accessorial embellishments of the uperstructure.

Foremost, then, among these accomplishments, is that of water colour painting, which, from the developement given to it of late, appears amongst us a new art; there can be no doubt that, in the hands of a judicious architect, this art may prove a valuable acquisition; but indiscriminately pursued and applied, as it frequently is with us, as a substitute for accuracy of form in drawing, it may act as a serious check to the progress of architecture. It has this pernicious quality, it easily captivates the mind of the student, and early destroys that relish for those more severe studies which are so necessary to his future excellence. Through the means of water colour painting, defects in architectural composition are frequently cloaked, which, when the building is in progress, appear in all their nakedness, to the mortification and *surprise* of the employers, and to the lasting discomfiture of the architect; and doubtlessly the forced and conventional style of setting off perspective views has led to the complaint so often heard in this day, that buildings, at their completion, fail to produce the effect they had in drawing, in short, that the drawing was a deception; we may feel assured that so fallacious a system is wholly incompatible with the attainment of excellence in so severe an art as that of architecture, and that if we wish to leave behind us buildings which shall strike posterity, as those buildings which the Italians have left do us, we must be content to submit ourselves to the same sage and sober method of studying which those great masters pursued, and then we shall enter the field with an advantage in our favour; for be it remembered, that the Italian architects were obliged to glean, from the works of their Roman ancestors, all they knew of Greek architecture; whereas, to us is disclosed the *mine* of Greek art itself, enabling us to go at once to the fountain head of taste, and of obeying, to the very letter, the advice which the Roman poet gave to his countrymen, when he told them to study the works of the Greeks by day and by night:—

" ———— vos exemplaria Græca
Nocturna versate manu, versate diurna."—Hor.

ON THE STANDARD OF ARCHITECTURAL BEAUTY AND SYMMETRICAL FORM.

By John Rooke, Esq., *Author of "Geology as a Science.*

In what may be called our own day, architectural forms that avowedly go by the name of taste, would seem to have fallen into all but ideal conceptions. A train of discussion has however been introduced into the Architect's Journal, based on the pure freedom of criticism, which is likely to uproot the inveterate conceits of the past ere long. Heaven's laws are all founded on omniscience, directed by the infinite wisdom of Almighty power. Were the universe divested of symmetrical proportions, by which each part sustains its duties in an infinite system, or bereft of the divine will, Chaos would necessarily lay prostrate the harmony of the heavens. But this is not so. God rules. Mind is more mighty than passive substance. Physics place the signet of universal truth on this comprehensive law, so conspicuously shown in all that comes within our means of observation. Mind has rendered all substance a self-acting instrument *on substance* by the adoption of such unification of purpose. We must believe in this ere we shall be able to take in science a single step, which is not empirical. All magnitudes of substance, which the intelligence of man is able to convert into substantial forms, and in which that substance operates upon itself, speedily fix their own limits, and would therefore break down under the influence of excessive weight. In the hands of heaven's laws, the extent of symmetrical harmonies is illimitable in magnitudes and exactness of proportions, in perfect conformity to a unity in design, worked by physics, as created by a Godhead, whose Almighty dominion nothing is either too extensive nor too small.

We may put our definitions on extent, and call this science, yet it is nothing beyond an amusing bubble, until we apply such definitions to the investigation of physical extent and combination in active forces. By such means we discover the universal and varied forms in which physics exist, and learn our own ignorance in the perfections and exactness of natural laws, even in the most trivial details, worked to their distinct ends, by that all-seeing mind which has made itself known through the medium of organic substance, working itself into like ends and means that are employed by man, when he embodies his conceptions and will in works of stone, wood, iron, or other materials, causing them to assume a self-working form for some end desired.

We so far observe two classes existing in forms of art. Those of heaven; and those of lowly man. In the first class, the more we study them, the more we find the adaptation of their provisions suited to their several uses. We find both a due quantity and quality of the materials employed to produce the ends required, neither more nor less, and taking the precise form held in view for attaining the object designed. This principle is constant in each and all of the works of the Deity, however opposite may be the magnitudes of such organic framework. The spheres of the heavens are so exactly adjusted in magnitudes as to retain their places truly; and work out those comprehensive changes in the phenomena of our earth which geology, as a science, based on the unity of divine wisdom, so plainly figures out to us. Though the earth may fly in its orbit at the rate of 68,000 miles in each hour, and turn on its axis more than 1000 an hour, yet these mighty motions, otherwise certain to disturb the waters of the earth, and cause them to roll over the most lofty eminences, have been effectually bridled by a depository process, which has made a fruitful land, symmetrical in surface lineaments, to appear from beneath those proud waves which have been thus stayed. By the same lofty destinies, and by the application of similar laws, every secure haven for ships, found on the borders of the great deeps, has its origin. We find the sturdy oak provided with sufficient strength of timber, and durability of quality to withstand the blasts of almost ten centuries. In that slim animal the hare we find material enough to impart to her the strength requisite for speed, without any of that unnecessary lumber, which would retard her foot, and operate as a drag upon her course. The greyhound may excel her in stride, and be able speedily to overtake her; yet her adaptation for turning more readily than her pursuer, chiefly owing perhaps to her more supple joints and less bulk, is suited for preservation. The ox, the horse ,the elephant, and indeed all other animals, are framed on symmetrical and mathematical rules which serve their wants and contribute to their preservation. So that we detect a unity prevailing throughout, which we must accept as constituting the only symmetry, harmony, or beauty which can exist—because the best uses are always made of any sum of materials in hand. All this exhibits the means by which in every instance conception and will gain an ascendancy over passive material bodies, and impart to them unity in beauty and adaptation to their uses. Symmetrical correspondences, which all admit to be a rule of beauty when truly adapted to their several purposes, form by no means an ideal taste, but a geometrical and mathematical rule rigidly observed in every instance. Who would recommend the drawing of circles and squares by taste? Nobody. Even a school-boy with his compasses and rules of art by which such figures are formed, would far outstrip in exactness of outline, the most accomplished artist that ever lived, had he no help except mere taste.

Coupling these observations with what has been given by the correspondents of the Architect's Journal, on the geometrical and mathematical harmonies of Gothic Architecture, it is plain that a fresh spirit in architectural design has been evoked. We claim for our day the age of science and civilization, and yet on what evidences does the claim depend? Do we prove our assumptions by a belief in the universal harmony of physics, springing from the causation of Almighty wisdom; or by the self-sufficiency of an empiricism, which utterly denies all connexion between philosophy and the laws of heaven? Why is it not obvious that we have a philosophy distinct from every religious consideration; and religious impressions which disclaim all evidences from philosophy; evils obviously existing because violent and bewildered extremes can neither agree with true science, nor with the purity of religion and morals. Mind is a universal power, of the mysteries of which we know nothing, except that it always works in pure physic according to geometrical and mathematical forms, upon the nearness of which to our frail bodies or distance from them we are totally unable to speculate.

Let this be accepted as the religious and philosophic belief of the English monks in the thirteenth century, as shown by the symmetrical harmony of their ecclesiastical edifices, and our ignorance and vanity are at once apparent. Yet no sooner do we observe scepticism, religious indifference, or bigotry creep into the public mind, than we find a decay in Gothic Architecture first appearing; and in less than two centuries it may be said to have been wholly lost, insomuch as the uniformity of geometric and mathematical rules were concerned. The purity of Gothic Architecture, (what a contemptuous name!) obviously sprang from the religious purity of the English monks in the thirteenth century, believing, as they must have done, that Almighty volition is manifested in the exactness of physics, geometrically and mathematically balanced in every work of the divine will. If we collect our proofs of this, from the day of Bede, in the eighth century, to that of Roger Bacon, in the thirteenth century, we shall discover one of the chief means, by which, in these five Gothic centuries, as we vainly call them, architecture and science had risen to a state of pre-eminence, which ought to make us blush for our own day, and acknowledge what lessons of wisdom we yet owe to the works of the Gothic barbarity bequeathed to us. Most unfortunately, according as papal bigotry and superstition vitiated the religious purity of every succeeding day, an opposite error crept in; and the world became all but divided between a superstitious despotism, which denied all reason in philosophy, and either a scepticism or a religious indifference, which promulgated a philosophy, independent of every religious consideration. In three centuries the lamp of genius, so brilliantly lit up at the fountain of heaven's laws, as evinced in the geometrical and mathematical exactness of Gothic Architecture, went out, and gave place to a race of imperfect copyists.* There can be no beauty but that which is symmetrically and mathematically adopted to the uses and ends held in view. Decoration, on all the rigidity of these severe rules, is displayed in every surface lineament of our globe; it is a scene of uses and beauties combined by the modus operandi of attributes divine. Ignorance may either overlook or deny this; and scepticism in the weight of its prejudices may vainly strive to hide the lamp divine under a bushel of follies, yet it is mildly bursting into the face of day in spite of either dullness supreme, or wilful blindness the most obtuse.

Ere such the proud day of success arrives, a vast preparation must be made. We must see distinctly what it is that we want. We must forego all baseless taste; and put a physical taste in its place. Neither papal superstition, nor its opponent scepticism, based on the foolish conceits of vain men, can serve us in the mighty acquisitions to be gained. These have not promoted, but retarded a development of those noblest faculties in man, which alike raise the standard of our religious belief, our moral qualities, and the perfections of our civil institutions. For not a little remarkable is it, that the age, which furnished us architectural remains so splendid, preserved if not matured our free institutions, amidst a period of turbulence and violence disturbing Europe at large. What I humbly ask then is, that men so well qualified as Mr. Cresy and Mr. Bartholomew, should go on and fear nothing.

[These remarks border too much on transcendentatism to be within the usual scope of our columns, but as we know they represent faithfully the ideas of a large class both here and abroad, we should have considered ourselves as neither doing justice to the subject nor the author, had we not availed ourselves of his proffered permission to consult our own taste in suppressing such portions of the paper as were not conformable to our views.—EDITOR.]

* We trust the earned author will excuse us for omitting some too flattering compliments to ourselves.

ENGINEERING WORKS OF THE ANCIENTS, No. 1.

THE PERSIANS.

Engineering has its archæology as well as architecture, the monuments of the Egyptians, of the Persians, of the Romans, are subjects which interest every class of readers. To some it may appear that the profession of a civil engineer is but of modern growth, it certainly may be so considered as regards its recent progress, but to the attentive observer a long chain of history is visible which records the labours of engineers, not for hundreds of years merely, but for thousands. On the engineering profession therefore the contemplation of the works of their predecessors is imposed as a task, if they are at all desirous that their successors should pay the same homage to themselves. The works of classic authors abound with accounts of interesting works, the descriptions of some of which we mean to copy into the Journal, as into a common-place book, trusting that it can never be considered useless to any man to contemplate the glories of the past. For this purpose we shall from time to time put down as they occur to us, extracts from the several authors, who have left materials for the subject of our enquiries.

Our present paper will principally be devoted to the works of the Persians and the Babylonians, which belong to one of the first schools of which we have authentic records. The history of this period forms the first in the annals of engineering, as now taught in this country, for the rudiments of the science laid down by the Persians, have, by successive nations, been transmitted to us. Persia being, like Egypt, a country traversed by a large river, and requiring extensive hydraulic works, naturally led to considerable proficiency in this branch, which would naturally be later of introduction among the continental Greeks, to whom it was taught by the Ionians in the Persian service. The Persian monarchs, independently of their own engineers, also became masters of the services of those of Egypt, Babylon, and Phœnicia, each of which, as we shall see, had also peculiar opportunities of study. From the Greeks engineering passed to the Romans, and so through the middle ages down to the present time, affording an example, paralleled in few professions, of rules of practice being transmitted uninterruptedly for more than twenty-five centuries, and illustrated from the earliest period by specimens now existing.

The materials for the ensuing descriptions are principally derived from Herodotus, who had authentic sources of information as to most of the works which he described. They are, as before stated, chiefly hydraulic works, and illustrate much of the antiquities of that important department of engineering.

CANAL OF MOUNT ATHOS.—CUTTING.—THE GOD OF THE ENGINEERS.

In the course of the war of the Persians against the Greeks about the year 481 B. C., Herodotus* relates that, in order to avoid shipwreck on the dangerous coast of Mount Athos, Xerxes determined on cutting through the isthmus by which it is joined to the mainland, and so making a canal for the passage of his fleet. Herodotus says that three years were spent upon this work, the Persian fleet having been ordered to the port of Eleus in the Chersonese, and all the forces on board being compelled by turns to dig, and open a passage through the mountain. In this they were assisted by the adjoining inhabitants, and the direction of the works was confided to Bubaris, the son o Megabyzus, and to Artachæus, the son of Artæus, both Persians.

Athos is described as a mountain of considerable magnitude, leaning upon the sea, and well inhabited, (now, we may observe, by monks). It terminates to the landward in the form of a peninsula, and makes an isthmus of about twelve stades (a mile and a half) in length. The

* Polymnia 7.

peninsula so formed consists of a plain with a mixture of little hills, from the coast of Acanthus to that of Torone. On the mountain and other parts were the towns of Dion, Olophyxus, Acrothoon, Thysus, and Cleone, and on the isthmus stood Sana. The Persians having drawn a line before the town of Sana, divided the ground among the several nations; and when the trench was considerably sunk, those who were in the bottom stages contrived to dig, and delivered the earth to men standing on ladders, who handed the same again to such as were placed in a higher station, till at last others who waited to receive the burthen at the edge of the canal, carried it away to another place. But by digging in a perpendicular manner, and making the bottom of equal breadth with the top, all the workmen, except the Phenicians, drew a double labour upon themselves: because the earth, as it is natural, fell down continually in great quantities from the upper parts. The Phœnicians alone, continues Herodotus, shewed that ability, on this occasion of which they are so much masters at all times: for they opened the part which was assigned to their care twice as large as others had done; and sloped the ground gradually till they came to the bottom, they then found the measure, equal with the rest. So much for the mode of cutting pursued two thousand three hundred years ago. We are thus enabled to ascertain the origin of the slope, and the period at which its recognized introduction into the art took place. The number of workmen employed, says our author, was so great that in a meadow adjoining they had a market furnished with great abundance of corn brought even from Asia, and there was also a temporary court of justice formed perhaps on the piepoudre system. Herodotus is by no means disposed to approve of the necessity of the work, for he rather ascribes it to ostentation, being of opinion that it would have been much easier for Xerxes to have had his fleet carried over the land. The canal was of a sufficient breadth to carry two ships sailing in front, and at each end were deep trenches to prevent the sea from filling it up, it was completed by the time the Persian army arrived at Acanthus, in the neighbourhood (about 481 B. C.)—At this time died Artachæus, one of the engineers, who appears by all accounts to have been one of the greatest men of the day, for he was in stature the tallest of all the Persians, and wanted only the breadth of four fingers to complete the full height of five regal cubits: his voice also was stronger than that of any other man. By descent he derived his blood from the noble family of Achæmenes, and was much esteemed by Xerxes, who greatly lamented his death, and caused him to be interred with great pomp. All the army was employed in erecting a monument to his memory; and the Acanthians, admonished by an oracle, honoured him as a hero with sacrifices and invocations. "Such," says Herodotus, "were the demonstration which Xerxes gave of his concern for the loss of Artachæus;" and thus did the profession obtain the patronage of a demigod from their own body, to whom if they like they may build temples at this day.—In the meanwhile we suggest to our antiquarian friends, whether the Persian engineers swore by Artachæus, and whether any devout modern would be justified in using the same ancient form.

The fleet, it seems, according to orders from Xerxes, passed through the canal of Mount Athos, and so into the bay on the other side. Our author further adds, that the people of Acanthus, in consideration of the great attention they paid in making the canal, were rewarded by the king with vests of honour.

In the Babylonian district, the people were, as in Egypt, well supplied with canals, principally for the purposes of irrigation, the water being distributed from them by manual labour, or by hydraulic engines. The largest of these canals,* continued with a south-east course from the Euphrates to that part of the Tigris where Nineveh stands, and was capable of receiving vessels of burthen. These canals and the river were navigated by a peculiar kind of skin boat or coracle, to which Herodotus devotes particular attention.

PASSAGE OF RIVERS.—THE HALYS—THE GYNDES—THE EUPHRATES—THE DANUBE—THE STRYMON.

In the course of the war of the Lydians against the Persians, Cræsus found it necessary to cross the river Halys,† when by the advice of Thales, the Milesian it is said, that he caused the river to be divided into two branches, as if he were going to make a bridge—the diversion of streams being a resource well known to the ancient engineers both of the east and the west. He sank a deep trench, which commencing above the camp, from the river, was conducted round it in the form of a semicircle, till it again met the ancient bed. It thus became easily fordable on either side.

Cyrus in his war with the Babylonians made use of a similar expedient, with regard to the river Gyndes, but from other motives. The Gyndes is described by Herodotus (Clio) as rising in the mountains of Matiene, and passing through the country of the Darneans, loses itself in the Tigris. Whilst Cyrus was endeavouring to pass this river, which could not be performed without boats, one of the white consecrated horses boldly entering the stream, in his attempts to cross it, was borne away by the rapidity of the current and totally lost. Cyrus, exasperated by the accident, made a vow, that he would render this stream so very insignificant, that women should hereafter be able to cross it without so much as wetting their knees. He accordingly put off his designs against Babylon, and divided his forces into two parts: he then marked out with a line on each side of the river, one hundred and eighty trenches; these were dug according to his orders, and so great a number of men were employed that he accomplished his purpose, but thus wasted the whole of that summer. It is supposed however that he was induced to undertake this work for the purpose of averting some omen.

On his arrival at Babylon, however, he had to carry on hydraulic works with a more important end. Finding the city strong and well provided, and that its reduction by force or famine seemed impracticable he had to take other measures. He placed one detachment of his forces where the river first enters the city, and another where it leaves it, directing them to enter the channel and attack the town wherever a passage could be effected. After this disposal of his men, he withdrew with the less effective of his men to a marshy part of the river, near which there was a kind of reservoir, said to have been constructed by Nitocris, Queen of Babylon, not long before. Cyrus here pierced the bank, and introduced the river into the lake, by which means the bed of the Euphrates became sufficiently shallow for the object he had in view. The Persians in their station watched the proper moment, and when the stream had so far drawn off as to be no higher than their thighs, they entered Babylon without difficulty.

Darius Hystaspes* in his expedition against the Scythians ordered a bridge to be thrown over the Ister or Danube by the Ionians. It was placed two days passage from the sea, at that part of the river, where it begins to branch off, but of its mode of construction nothing is said, although it may be inferred that it was of boats. Darius, when he arrived at the Ister, passed the river with his army, he then commanded the Ionians to break down the bridge, and to follow him with all the men of their fleet, but by the advice of Coes, a Mytilenian officer, he allowed it to remain, leaving it under the guard of the Ionians, with orders if he did not return in sixty days to break it down. The Scythians knowing this sent a deputation to the Ionians to persuade them to break down the bridge, or to maintain it only for the stipulated time, to which latter proposition they assented. The delay of sixty days having however expired, the Ionians by the advice of Histiæus of Miletus, still maintained the bridge for the Persians, but to prevent the Scythians cutting off the retreat, broke that portion near the Scythian shore. Darius arriving in the night with his army, Histiæus with the fleet restored the bridge.

Bubaris and Artachæus, the engineers of the Mount Athos canal, were also charged during the campaign of Xerxes against the Greeks, with the construction of a bridge over the river Strymon in Thrace. For these bridges, says the author so frequently quoted,† Xerxes provided cordage made of the bark of the biblos, and of white flax. This is all the account we have received of the bridge, except that the army afterwards passed over.

PASSAGE OF SEAS.—BOSPHORUS—HELLESPONT—GULF OF SALAMIS.

Darius,‡ having determined on an expedition against the Scythians, gave orders to throw a bridge over the Thracian Bosphorus, or as it is now called the canal of Constantinople. This bridge was placed at Chalcedon, or as Herodotus conjectors nearly midway between Byzantium and the temple at the entrance of the Euxine, constructed under the direction of Mandrocles, a Samian, who executed it so much to the satisfaction of Darius, that he made him many valuable presents. With the produce of these presents Mandrocles caused a representation to be made of the Bosphorus with the bridge thrown over it, and the king seated on a throne, reviewing his troops as they passed. This he afterwards consecrated in the temple of Juno, with an inscription paraphrased by Beloe thus—

Thus was the fishy Bosphorus inclos'd,
When Samian Mandrocles his bridge impos'd:
Who there, obedient to Darius' will,
Approv'd his country's fame, and private skill.

This is perhaps one of the earliest instances of a votive offering, and of an artistical commemoration of an engineering work.

* Herodotus, Clio.
† Herodotus, Clio.

* Herodotus—Melpomene.
† Herodotus—Polymnia.
‡ Herodotus, Melpomene.

Xerxes the successor of Darius, in his previously mentioned campaign against the Greeks, also had occasion to pass the same sea, but at another point.* While he was preparing to go to Abydos, numbers were employed in throwing a bridge over the Hellespont from Asia to Europe. The coast toward the sea from Abydos, between Sestos and Madytus in the Chersonese of the Hellespont, is described as rough and woody: the distance from Abydos being seven stades, or nearly a mile. The work however commenced at the side next Abydos. The Phœnicians used a cordage made of linen, the Egyptians the bark of the biblos. The bridge was no sooner completed than a great storm arose which destroyed the whole work, which when Xerxes heard, he ordered, as is well known, the Hellespont to be flogged, and a pair of fetters to be thrown into it. The engineers got worse off, for they were sentenced by the king to be beheaded. Our historian goes on to say with some naïveté that a bridge was then constructed by a different set of engineers—which we should naturally imagine, for it is difficult to conceive how men who were beheaded, could very easily preside at works *à la Saint Denis*. The mode employed, as far as it can be made out, was to connect together ships of different kinds, some long vessels of fifty oars, others three banked gallies. These were arranged in a double row, one set transversely, but the other in the direction of the current. When these vessels were firmly connected to each other, they were secured on each side by anchors of great length; they left however openings in three places, sufficient to afford a passage for light vessels, which might have occasion to sail into the Euxine or from it. Having performed this, they extended cables from the shore, stretching them upon large capstans of wood, for which purpose they did not employ a number of separate cables, but united two of white flax with four of biblos. These were alike in thickness, and apparently so in goodness, but those of flax were in proportion much the more solid, weighing not less than a talent to a cubit, an expression showing that the ancients knew how to appreciate the qualities of cordage. When the pass was thus secured, they sawed out rafters of wood, making their length equal to the space required for the bridge; these they laid in order across upon the extended cables, and then bound them fast together. They next brought unwrought wood, (fascines qy.) which they placed very regularly upon the rafters: over all they threw earth, and which they raised to a proper height, and finished all by a fence on each side, that the horses and other beasts of burden might not be terrified by looking down upon the sea. Two ways were thus made, one on each set of boats; on one of these ways, namely, the northern, the infantry and cavalry passed, and over the southern the camp followers and the baggage. The bridge was afterwards destroyed by a storm.

At a subsequent period of the campaign Xerxes contemplating flight, for the purpose of amusing the Athenians, he made an effort to connect the island of Salamis with the continent, joining for this purpose the Phœnician transports together to serve both as a bridge and a wall.

BRIDGE.—EUPHRATES—BRICKS.

Babylon,† being divided by the river Euphrates into two distinct parts, whoever wanted to go from one side to the other was obliged to pass the water in a boat. To remedy this general inconvenience, and mentioned by the historian as an expedient not usual, Nitocris, Queen of Babylon, determined upon building a bridge, from which period we may date the formation of permanent bridges as a part of engineering. Having procured a number of large stones, she changed the course of the river, directing it into a canal prepared for its reception, and so into a large marsh or reservoir. The natural bed of the river being thus made dry, the embankments on each side near the centre of the city were lined with bricks, hardened with fire. Upon this we may remark that the Babylonians used two kinds of bricks, the common brick, baked in the sun, and another brick burnt in a furnace; this latter kind was most probably used on this occasion, as the more durable. Nitocris, then with the stones before prepared erected a number of piers, strongly compacted with iron and lead; on these piers a platform was laid, which was removed at night to prevent communication between the different quarters of the city. The bridge being completed, the river was allowed to return to its natural bed. This work, according to Diodorus Siculus, was five furlongs in length.

EMBANKMENTS.—EUPHRATES—ACES—SLUICES.

Nitocris, just mentioned, is said to have been the author of several other remarkable works, some of which are however, doubtful. Being fearful of the ambition of the Medes, she is said, for the purpose of preventing communication with them by the Euphrates, to have diverted the course of the river above Babylon, by sinking a number of canals, and giving it a winding shape. To restrain the river on each side, she raised banks, which are described as wonderful on account of their enormous height and substance. A large lake or reservoir is also attributed to this queen, its circumference being stated at fifty miles, but it is more than probable that her works were confined to reclaiming part of a natural marsh, or to securing the banks; these she lined with stones brought thither for that purpose.

* Herodotus, Polymnia.
† Herodotus, Clio.

Herodotus relates in his third book an account of operations on the river Aces, on which doubt has been thrown, but which whether true or false, will be equally interesting as illustrating the engineering opinions of the ancients. He says that there is in Asia a large plain surrounded on every part by a ridge of hills, through which there are five different apertures. It formerly belonged to the Chorasmians, who inhabit those hills in common with the Hyrcanians, Parthians, Sarangensians, and Thomaneans; but after the subjection of these nations to Persia, it became the property of the great king. From these surrounding hills there issues a large river called Aces: this formerly, being conducted through the openings of the mountain, watered the several countries before mentioned. But when these regions came under the power of the Persians, the apertures were closed, and gates placed at each of them, to prevent the passage of the river, from which expression we infer that the Persians were acquainted with the use of sluices. Thus on the inner side, from the waters having no issue the plain became a sea, and the neighbouring nations, deprived of their accustomed resource, were reduced to extreme distress from the want of water. In winter they, in common with other nations, had the benefit of the rains, but in summer, after sowing their millet and sesame, they required water, but in vain. Not being assisted in their distress, the inhabitants of both sexes hastened to Persia, and presented themselves before the palace of the king, made loud complaints. In consequence of this, the monarch directed the gates to be opened towards those parts where water was most immediately wanted, ordering them again to be closed after the lands had been sufficiently refreshed: the same was done with respect to them all, beginning where moisture was wanted the most. This, however, was only granted in consideration of a large donation over and above the usual tribute.

That the Persians were well acquainted with the operation of damming appears also by other instances. Xerxes having examined the Peneus, a river of Thessaly, inquired whether it could be conducted to the sea by any other channel, and received from his guides, who were well acquainted with the country, this reply: "As Thessaly, O King, is on every side encircled by mountains, the Peneus can have no other communication with the sea." "The Thessalians," Xerxes is said to have answered, "are a sagacious people. They have been careful to decline a contest for many reasons, and particularly as they must have discerned that their country would afford an easy conquest to an invader. All that would be necessary to deluge the whole of Thessaly, except the mountainous parts, would be to stop up the mouth of the river, and thus throw back its waters upon the country."

(To be continued.)

A SUBSTITUTE FOR CHIMNEY-POTS.

Sir—Owing to the many accidents which have occurred through the late storm, from the falling of those ugly and useless appendages (called chimney pots), which disgrace the noble works of architecture in our metropolis, I am induced to trouble you with a few lines, should you consider them worthy of insertion in your valuable publication. It has frequently been a subject of my thoughts, how chimney pots were first introduced, as they certainly are most useless and unsightly articles.

Perhaps, if I draw the attention of your readers to the form of a tin horn, such as is used by guards of mail coaches, the principle of chimneys will be better and more easily understood; if builders will only try the experiment, I feel satisfied they will no longer continue one of the greatest imperfections of our common system and mode of building. If the large end of the horn be placed downward over some ignited bituminous matter, we shall find only part of the smoke will ascend; but if we place the small end down, we shall not only find the draft greatly increased, but the smoke will ascend freely up the tube.

Hoping these observations will be of service to the public,

I remain, Sir,
Your obedient servant,
J. R. B., C.E.

Brixton Road,
January, 1841.

REMARKS ON THE MORTAR USED IN ANCIENT BUILDINGS.

WITH OBSERVATIONS AND DIRECTIONS FOR PREPARING MORTAR IN A MORE PERFECT MANNER THAN THAT NOW IN PRACTICE.

The great perfection to which the arts have attained cannot be denied; yet on examining the monuments of former ages, of which many are still to be seen in this country, it does appear that the ancients had some manner of making and using mortar for their buildings, of which our modern artists seem either to be ignorant, or do not choose to put in practice. Although the grand edifices raised under the direction of the artists of the present age, is a proof that our modern masters, by the study of the monuments left us by the ancients, have been enabled to construct buildings vying with their patterns; yet the moderns are still behind the ancients in the construction of buildings with small or promiscuous materials, with that degree of solidity which seems almost to set time itself at defiance.

There is no doubt little difficulty in raising lasting edifices by building immense blocks of solid stone, one upon another—but if we say nothing of the enormous expense of this mode of construction, even where the materials are to be found in the vicinity, there is some consideration necessary when works which require durability are to be constructed, where no large materials can be readily found. Hence the erection of buildings which may be of the utmost importance in a national point of view, as well as to individuals, has to be abandoned, on account of the enormous expense attending the modern plan of construction.

On a careful examination of many of the old castles in this country, it will be seen that the materials which have been used are of the most ordinary kind; and from the manner in which they have stood for such a long period of time, it does most readily occur, that the mortar used in these buildings, has been prepared in a different manner from that practised by modern builders. In fact it will be found that many of these old buildings have been put together with almost every description of stones down to the smallest pebble collected from the bed of the brook, and where no heavy carriages or complicated machinery have been required to construct the most extensive works.

Our ancient bridges and aqueducts all exhibit specimens of the same kind of construction with very small stones; depending therefore on the superior manner of preparing the mortar by which these small materials have been cemented together.

Thus there seems to be an art lost, and in place of endeavouring to recover this art by a series of well conducted experiments, men of genius, and particularly our modern philosophers, seem to have principally in view to bestow their labours in pushing into the world books filled with abstract calculations which they understand only on paper. These calculations are, however, by far too nice, and it is much to be feared that few of the writers could be found to reduce them to practice—and as practical men do not understand them, they are useless to the world. It may be very well for the physician to write a learned prescription intermixed with hieroglyphics, to the apothecary who understands it; but alas! the carpenter and builder have neither time nor inclination to enter into the abstruse analysis of the philosopher. Bred to labour from their early youth, it is only from experience they are accustomed to learn; and it is therefore only from a course of well regulated experiments, described in plain language and simple figures, that the labouring artist's attention can be arrested.

It would therefore in almost all cases be the means of more rapidly diffusing a knowledge of the useful arts, were our seminaries furnished with the means of exhibiting in some degree of experiment, specimens of the various useful arts. For without experience what is the young engineer who is sent forth to direct the operations of a siege, to raise fortifications, form aqueducts, or construct bridges? It is clear he has yet to learn from the labouring artificer, the essential parts of his business; and thus he is sent forth only with the name, to learn from those of inferior station, who are here found capable of giving instructions from experience, where fine theories and abstruse analysis can be of little avail.

To return, however, to our ancient buildings, where it appears neither time nor labour was lost in the execution. Many of them seem constructed of little else than rubbish thrown together with an outer coating of small stones, or pebbles from the brook, but built with a kind of mortar which appears to have been thin enough to penetrate the smallest crevices, and to form a solid, compact, nay almost an impenetrable body. And if the ruins are considered with the smallest degree of attention, it will convince us that all the secret of this mode of construction, consists in the preparing and using the mortar which has bid defiance to time, and to the tools of the quarrier to remove, after the lapse of ages. Every workman who has been engaged in taking down any of our old castles, will testify that he has always been able to remove the stone with greater facility than he could disengage the mortar.

How differently then must this mortar have been prepared from the very best which is now prepared by our modern builders: for the latter only dries to fall to dust again when broken into. Another of the grand qualities of the ancient mortar is its being impenetrable to water; and, in fact, the aqueducts for retaining and conveying water which are still to be seen, exhibit no marks of clay or other kind of puddle having been used for retaining the water. Therefore, it does appear that aquatic as well as other works, were frequently constructed of very small stones, by the builders of former ages, and that they were in the practice of forming parts of their buildings into cases or *caissons* of planking, by which means the mortar when run in amongst the interstices of the small stones, was prevented from escaping.

It can therefore be most readily conceived how easily a building of great magnitude may be constructed at a small expense, and that of the most durable and lasting kind, of materials with which almost every part of our country abounds, if we are only careful in the preparation of the mortar with which these materials are to be cemented together.

It does not appear that the ancients used any other ingredients in their mortar than lime, sand, or calcined earth, such as brick dust, when proper sand could not be procured; and therefore, as already mentioned, the whole secret seems to be the manner of preparation, of which some explanation will now be attempted.

It is presumed the fact is well known, that in the burning of limestone, the fixed air which it contains escapes, and the stone by this means loses its weight. It has indeed long been the practice to grind or slack the lime immediately after being burned, and by means of mortar mills (where the extent of the works can afford them) to prepare the hot mortar for immediate use for building or bedding large materials; but, it is a fact well known that this kind of mortar (to say nothing of the great expense of procuring it), would be useless in ordinary buildings, as the weight of the substance in thin walls composed of small materials, would not prevent the burstings, cracks, and sets, which would take place; nor, from the consequence of blistering which always happens when mortar prepared in this way, is used; rendering it unfit for plastering either to withstand the action of the weather, or for lining water courses: because it suddenly dries by the evaporation of its moisture, and consequently, immediately gives way to cracks and shrinking.

On the other hand lime-mortar after lying a considerable time in a sowered state, imbibes again the fixed air which was discharged in the process of burning, and when carefully examined in this state, presents a kind of transparent, or rather icicle, appearance, which destroys in a great measure the binding quality, and which, in our changeable climate, rarely or ever has the effect of cementing the building. The latter, however, is the manner in which almost all the lime mortar is most commonly prepared for building, both from a regard to economy as requiring less lime, and also with regard to labour; and, it is more than probable it was by hand labour also, that the builders of former ages prepared their mortar. It is therefore to this principle that observations have been directed, of which the following notice is submitted, and which it is hoped, if properly attended to, will enable those who wish to do so, to prepare and use lime-mortar not inferior to that of the ancients.

Sower together a quantity of lime and clean sharp sand for two or three weeks before being used; work this well and turn it aside, and as the proportion of the lime to the sand, will always depend on the quality of the former, all that is necessary is, to take care (in sowering), if the lime is of a rich quality, to put one-third less lime into the heap, than it is intended to be built with; and, if the lime is of poor quality, say only one-fourth less. (It may here be observed that in general lime of the poorer quality is best for cementing building.) When the lime which has been previously sowered, as before directed, is to be used in the building, or otherwise, it is to be again worked carefully over, and one-fourth of quick lime added in proportions, taking care never to have more in preparation than can be used in a short time; and this quick lime should be most completely beaten and incorporated with the sowered lime, and it will be found to have the effect of causing the old lime to set and bind in the most complete manner. It will become perfectly solid without the least evaporation to occasion cracks, which can only ensue in consequence of evaporation; and this can only happen from the want of proper union between the two bodies. But by mixing and beating the quick lime with the sowered mortar, immediately before it is applied to use, the component parts are brought so near to each other, that it is impossible either crack or flaw can take place. In short beating has the effect of closing the interstices of the sand, and a small quantity of lime paste is effectual in fitting and holding the grains together, so as to form a plastic mass by uniting the grains of sand which otherwise would not fit each other. This system will apply to lime-mortar for all descriptions of work, whether for building, plastering in the inside or outside of houses, water cisterns, ground vaults, rough casting, &c. &c.

It may not be improper to mention that whenever there is any difficulty in procuring proper sand for building, clay is an excellent substitute; and all that is necessary is, to make it into balls, and burn it, and then pound it like brick-dust, or pozzolano earth. There is no doubt, in addition to the superior scheme of making mortar in former ages, that, when they used only the small stone, which we see in the ruins of their buildings, they were in the practice of using temporary casings of boarding which they could move from place to place as the building advanced, and which would enable them to grout or fill up with their quick mortar all the interstices in the successive layers of stones. And moreover, by having the boarding of their centering for arches and conduits quite close, they were enabled to lay on, along with their stone, almost an impenetrable coating of plaster.

From the foregoing observations, it is hoped, it will be most clearly seen that an easy mode of erecting substantial and durable building is generally within our reach, and that the most inferior kind of stones may be used, providing proper care is taken in the preparation of the lime-mortar with which they are to be cemented together.

John Gibb,
M. Inst. C.E.

Aberdeen, January 2, 1841.

ON THE CONSTANCY OF CALORIFIC ABSORPTION,

EXERCISED BY THE BLACK OF SMOKE AND BY METALS; AND ON THE EXISTENCE OF A DIFFUSIVE POWER, WHICH BY ITS VARIATIONS CHANGES THE VALUE OF THE ABSORBING POWER IN OTHER ATHERMANTIC BODIES.

(Translated from the French of M. Melloni, *for the* C. E. & A. Jour.*)*

There were great difficulties to be overcome in the attempt to prove that the black of smoke, subjected to the action of different kinds of radiating heat, always absorbs the same proportions of them. The question would be immediately solved if we could successively expose the blackened body to equal radiations, drawn from several sources of caloric; for a thermometer plunged in the interior of the body would show by the greater or less elevation of temperature, whether the quantities of heat absorbed vary or not with the quality of the incident heat. When however we come to use the thermometer or thermoscope in experiments on radiating heat, it becomes necessary, as we shall hereafter see, to cover them with the black of smoke. On the other hand, to compare two forces, whatever the effect which they produce upon the measuring instrument must be estimated exactly in proportion to their intrinsic energy. Thus we cannot compute the relative intensity of rays of heat but by admitting the principle in question: the experiment therefore of a thermometer plunged in the interior of the body would be quite illusory.

The first operation is to take a disc of wood, of which one face is white and the other black; this is fixed vertically upon a stock moveable upon its axis, and having successively brought the two surfaces by a half revolution of the disc in presence of the radiation of a lamp concentrated by a glass lens, each time is collected with a very sensible thermometer provided with a reflector, the secondary calorific radiation projection by the side on which the direct rays fall, after this radiation has traversed a plate of glass interposed between the disc and the thermometer. In the case of the black face there is no sign of heat; but things are different with regard to the white face, from which is obtained a very intense indication of caloric. It is well known that white bodies can never be heated more than black bodies under the influence of any radiation whatever, and under the circumstances of the experiment the black face gives nothing; therefore the great action of the white face does not arise from the absorbed heat, but from a true dispersion, similar to the diffusion suffered by luminary rays and the exterior of opaque bodies. To prove the variable diffusive action which a white surface exercises on calorific rays from different sources, and the constant absorption of the black of smoke in all kinds of heat, a very sensible thermometer is used with a reflector, carefully sheltered from rays direct from the source and by it are measured the true secondary anterior and posterior radiations projected from the surface of an immoveable disc subjected to a given radiation. The same observations are repeated for several kinds of heat by employing two discs of thin cardboard, one painted black and the other covered with a substance more or less white The first of these discs constantly exhibits the same relation between the rays vibrated by the two faces, the second shows very different relations. Underneath is shown the relative results of four species of rays arranged according to the order of the temperature, of the sources from which they emanate.

Black disc	$\frac{10}{12}$	$\frac{10}{12}$	$\frac{10}{12}$	$\frac{10}{12}$
White disc	$\frac{10}{14}$	$\frac{10}{18}$	$\frac{10}{26}$	$\frac{10}{34}$

In order to enable us to draw conclusions from these figures, it is for the present to remark that the posterior face of each disc radiates in consequence of the heat absorbed while the anterior face acts at the same time by virtue of the radiations caused by absorption and diffusion; we therefore see 1st. That the black of smoke absorbs and disperses all kinds of calorific rays with the same energy. 2nd. That the diffusibility of caloric on the surface of the white disc increases with the temperature of the source.

As a detail of the other experiments would require too great a space, it will be sufficient to sum up here the general results.

1. The superficial layers of bodies cause to radiating heat a dispersion analogous to luminous dispersion.

2. We possess sure means of distinguishing calorific diffusion from the radiation derived from the proper heat of the body, notwithstanding both radiations are equally composed of elementary pencils radiating in every direction around the centre of action.

3. The black of smoke produces very little diffusion equal for all kinds of radiations.

4. That other substances, and especially white bodies are very different, as they strongly disperse rays from incandescence, and weakly disperse those which derive their origin from sources of temperature.

5. This special characteristic is enough to show that we must not attribute the phenomenon of calorific diffusion to every regular or irregular reflection whatever; for this would take place with the same energy for all kinds of heat.

6. The dispersive action of metals is generally speaking more intense than that of white bodies: it especially differs by its invariability, and on this point resembles the feeble diffusion observed in the black of smoke.

7. By comparison between the phenomena of calorific diffusion and those of luminous diffusion, it appears 1st. That the black of smoke is a true black matter, both as regards radiating light and heat. 2nd. That white bodies act with regard to radiating heat as coloured substances with regard to light. 3rd. That metals act upon calorific radiations as white bodies do upon luminous radiations.

8. The diffusion sends back a part of the incident rays proportionate to its intrinsic energy, and thus diminishes the calorific absorption of the whole portion of heat dispersed by the action of the surface.

THE PNEUMATIC MARINE PRESERVER.

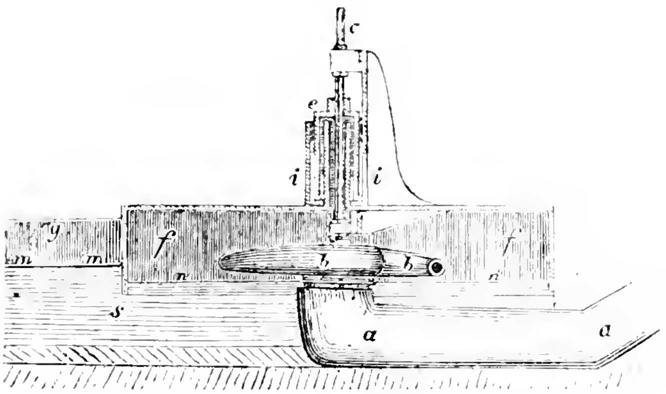
Sir—In viewing the many interesting and scientific exhibitions at the *Polytechnic Institution* in Regent Street, my attention was more particularly arrested by the model of a ship fitted up with a new invention, called the Pneumatic Marine Preserver: indeed, I was astonished to see the little vessel, though full of water and cargo, still keep afloat, and to a casual observer's eye, without the least aid, as the apparatus occupies so little room, and is so placed out of the way, that ninety-nine out of a hundred would not observe the reason of its buoyancy. While carefully examining the craft, a person who shows it to the public, suddenly exhausted the air, and she gradually sunk completely out of sight; but to my surprise, by a few strokes from the condensing air-pump, she immediately rose to the surface of the water, and again floated about.

Being an old sailor, I thought it a duty I owe to my fellow creatures to make it known to the public through your valuable Journal: and I would particularly advise captains to have their boats fitted up with the Patent Pneumatic Marine Preserver, as, in case of danger, they then become perfect life-boats, far superior to any yet invented for room, lightness, and buoyancy. If ever there was an invention of incalculable service to sea-faring men this is the one, and deserving of their utmost attention if they value life or property.

I remain
Your obedient servant,
An Old Sailor.

London,
January, 1841.

IMPROVEMENT IN MESSRS. WHITELAW AND STIRRAT'S WATER-WHEEL.



In the "Mechanics' Magazine" we have a suggestion for an improvement in Messrs. Whitelaw and Stirratt's Water Wheel, given in last month's Journal, of which the accompanying drawing shows the plan, which, with the assistance of Mr. George Whitelaw, Mr. James Whitelaw has invented for keeping the new patent water-mill out of tail-water. *a a* is the main-pipe, *b b* are the arms of the machine, and *c* is the top of its shaft. The arms work inside of an air-vessel *f f*, which is fixed down to a building, and is covered on the top, but has no bottom. The shaft passes freely through a hollow cylinder fixed above an opening in the top of *f f*, and there is another hollow cylinder *i i*, fixed also on the top of *f f*, and so large in diameter inside as to leave room for a third cylindrical part *e*, which is fixed upon the upright shaft to revolve easily in the space left between the other two cylinders. The top of *f f*, forms a bottom to the space which is between the two cylindrical parts first named, and *e* is fixed upon the shaft in such a manner that the joining will be air-tight. An inspection of the drawing will make the arrangement, &c., of the cylindrical parts intelligible. *g* is one side of the tail-race; *s* is the opening through which the water escapes from *f f*, into the tail-race.

Suppose now the space into which the cylinder *e* works sufficiently filled with water to form an hydraulic joint of the kind very commonly used in gas works; then, if the machine is set in motion, the air, which will in some instances be disengaged from the water, will remain in the vessel *f f*, and press down the surface of the water in it to the level *n n*, or even lower. In this way, the arms of the machine, although on a level below that of the surface *m m*, of the water in the tail-race, will work clear of the tail-water.

It may be found necessary to use a small pump to force air into *f f*, in order to lower the surface of the water. By running a quantity of water from the main pipe into the air-vessel through an arrangement of pipes similar to the water-blowing machine, air will be carried into *f f*. The space within which the cylinder *e* works may be supplied with water by a small pipe leading from *a a*.

A water-mill composed of two round plates, the one forming the top, the other the bottom of the passages for the water, with plates on edge and properly bent, running between them from the centre outwards, so as to make the space between the round plates all into arms, will work very well in tail-water. If a ring, projecting downwards is fixed to the under plates, then the bottom of the machine will rub on a film of air, instead of on water, and thus the friction will be diminished. This plan may be used instead of the one herein described, in certain cases.

IMPROVED JACQUARD APPARATUS.

A machine has recently been added to the mechanical department of the Salford Mechanics' Institution which promises for it a great increase of attraction. It is an invention of a gentleman of this town, and is called a Jacquard apparatus. When appended to looms moved by power (as in the present instance), or otherwise, it is capable of producing, either on light or heavy fabrics, not only a greater variety, but also a wider and more extensive range of pattern than any other kind of loom; it makes a top and bottom shed of any required depth, without the aid of weights and springs being attached to the healds. The design is formed, and may be varied at any moment by the application of paper cards, or wooden logs and pegs. It will weave with any number of shafts, from 2 to 30; and any length of pattern, up to 5,000 picks may be produced by it. The invention is a very important one to manufacturers. Other articles have likewise been added to the collection within the last few days, but our limits at present prevent us from adverting to them.—*Manchester Guardian.*

BIOGRAPHICAL NOTICE OF THE LATE MR. WILLIAM HAZLEDINE, IRON FOUNDER AND CONTRACTOR FOR PUBLIC WORKS.

(From the Shrewsbury Chronicle.)

With deep and sincere sorrow we record the death of our respected and endeared townsman, the eminent iron founder, William Hazledine, on Sunday, October 26, at his house in Dogpole, in the 77th year of his age.

It would be almost criminal to permit such a man to drop into the grave like an ordinary human being, and therefore we hastily present a few incidents in his busy and honourable career through life.

William Hazledine was born at Shawbury, and his parents removed, while he was very young, to a house at Sowbatch, near a Forge at Moreton Corbet, now Moreton Mill, about seven miles from this town. His father was certainly not wealthy: but his ancestors were highly respectable, their remains occupying tombs in the church-yards of Shawbury and Moreton Corbet: and these tombs the deceased, with filial regard, caused to be repaired a few years ago; he also presented two handsomely carved oak chairs for the altars of both those churches.

During sixteen or seventeen of his early years he worked around the vicinity as an operative millwright. His uncle, under whom he was chiefly brought up, was a man of considerable ability as a millwright and engineer; and, discerning the steadiness and talent of his nephew, he recommended young Hazledine, only 16 or 17 years old, to superintend the erection of machinery at Upton Forge, the property of the Sundorne Family: this was executed most satisfactorily. He afterwards became the tenant of this forge, and the farm belonging to it, and so continued in after life.

After the patronage of his uncle he removed to Shrewsbury, and entered into partnership with Mr. Webster, in Mardol, then a clock-maker, but afterwards an ironmonger and the patentee of a washing-machine. Their first foundry was in Cole-hall, or Knucking-street, in this town; but the speculative and energetic mind of Hazledine having increased the business, more space for workshops, and an increased expenditure for that purpose, amounting to about 2,000*l.*, were necessary: his partner being cautious and timid, a dissolution of partnership took place.

Mr. Hazledine purchased the ground in Coleham, where his present foundry is situated, which has now four gables fronting the road. He prudently first erected one workshop, which occupied only one of these gables; but as business increased he extended his shops, and numerous other erections in the vicinity. He subsequently occupied a foundry near Ruabon, iron works at Calcott, lime works at Llanymynech, timber yards, brick yards, and coal wharfs, in various places.

About this time Billingsley iron mines, near Bridgnorth, were offered for sale in Chancery. Hazledine attended the sale in London, and found there was some jockeyship employed to depreciate the property, and prevent the sale, certain parties being anxious to purchase the works without any competition. Hazledine's sagacity saw the trick; he bid with spirit: at length one of the parties, who wanted to purchase, came to him, and whispered—

"Do you know what you are doing? These mines and works have not a good title, and you will have to pay the expenses in Chancery if you purchase them."

In an audible voice Hazledine answered—

"A bad title to the property, is it, eh? and a Chancery suit, too, eh? Well, I have bought many things, and I will now try to buy a Chancery suit.

He did purchase the property, but immediately sold it, gaining several thousand pounds. The property finally turned out ruinous to the speculators.

In November 1804, at midnight, a fire took place in a room which was the receptacle for his patterns for castings. Mr. Hazledine was from home, but his wife (a daughter of Mr. Brayne, of Ternhill), an uncommonly strong-minded woman, heard the cry of "Fire in Hazledine's foundry," whilst in bed with her infants, and immediately getting up, gave directions for saving the books, papers, and other valuables, which caused their rescue from the flames, whilst a vast quantity of other property was consumed with the building. Mr. Hazledine was then the captain in a company of volunteers; and his company, comprising chiefly his own workmen, was merrily called "The Vulcans." The colonel, Sir Charles Oakely, Bart., and the whole corps, were roused, and much property was saved. It was estimated that the loss was 1,500*l.*, and that about two-thirds were covered by insurance.

Undaunted by the calamity, he rebuilt and extended his foundry, and carried on his various speculations, above enumerated, with great energy. Thomas Telford, who in after life became the celebrated engineer, had been patronised by Sir William Pulteney, and employed in reconstructing some parts of "The Castle" in Shrewsbury, became acquainted with Hazledine, and these kindred spirits formed an intimacy which lasted through life.

Telford soon after was engaged in constructing the Ellesmere and Chester Canal, and Mr. Hazledine became the contractor for the Chirk and Pontycysylte Aqueducts, the latter being one of the most magnificent works of the kind in Europe, which he completed so entirely to the satisfaction of Mr. Telford and the proprietors, that he was immediately engaged in all the national works in which the Government at that time plunged. The erection of the stupendous locks on the Caledonian Canal was entrusted to him, and executed to the entire satisfaction of the engineer and the country.

Hazledine's fame was now established, and he was employed in a series of great works. The following is a summary :—

Pontycyssyle cast-iron Aqueduct over the river Dee, and the valley at Llangollen, in 1802.

A Bridge, 150 feet cast-iron, over the river Bonar, in Scotland.

A Bridge, 150 feet ditto, over the river Spey, in Scotland.

The Lock-gates on the Caledonian Canal.

The beautiful Waterloo Bridge, 105 feet span, near Bettws-y-Coed, on the Holyhead road.

The iron Swivel Bridges at Liverpool Docks.

The Liverpool New Market Columns.

A Bridge, 150 feet span of one arch, and two arches of 105 feet, over the river Esk, near Carlisle.

The Menai Suspension Chain Bridge.

The Conway Suspension Chain Bridge.

The Iron Roofs for the Dublin Custom House and Store-houses.

The Iron Roofs for Pembroke Stores, &c.

Many Swivel Bridges for Sweden.

A large quantity of three-feet Pipes for India, Demerara, &c.

A Bridge built for Earl Grosvenor, 150 feet, at Eaton Hall.

A Bridge over the Severn at Tewkesbury, 170 feet span.

A new Bridge over the Dee, 105 feet span.

A Bridge for Earl Morley, at Plymouth, comprising five arches, of 100 feet, 96, and 81 feet span.

A Bridge at Bath.

Holt Fleet Bridge, 150 feet, over the Severn, near Worcester.

The Swivel Bridges at the London Docks.

The Marlow Chain Bridge.

Montrose Chain Bridge.

Several small Iron Bridges in this county, and many others all over the kingdom, besides the Lock-gates on the Ellesmere and other Canals.

At the present moment, Hazledine's foundry is executing a very extensive work, namely, several pairs of iron lock-gates for Newport, in Monmouthshire, South Wales, each pair weighing 120 tons, the largest ever executed.

In 1832, when the present Queen, then Princess Victoria, and her august mother, the Duchess of Kent, honoured the Earl of Liverpool with a visit at Pitchford Park, near this town, Mr. Hazledine had the honour of receiving, through the Earl of Liverpool, the commands of the Royal personages to wait upon them at Pitchford Park, and explain the principles and construction of the Menai Suspension Bridge —Hazledine's greatest work. The Royal party expressed great satisfaction at the lucid and instructive manner in which the explanations were given, and the tact and shrewdness displayed in Mr. Hazledine's answers. Persons who were present describe the interview as most interesting. Mr. Hazledine received a present as a token of approbation; and we cannot avoid adding, from personal knowledge, that her Royal Highness the Duchess of Kent, when she passed over the Menai Bridge, examined every part of it minutely, according to Mr. Hazledine's description, and even entered the caves in which the iron suspension cables are fixed.

This is a slight view of Mr. Hazledine's public works, and it gives a portrait of him as a practical man. There are other features, which we are unable to paint with the warmth and fidelity which they deserve. His strong affection for the members of his family rendered his fireside one of the most happy round which an English family ever gathered. He was ever devising some simple means of increasing their enjoyments; and he attended personally to everything in which their comforts were involved. At that trying season, when the wheel of the "Union" coach locked into that of his gig on the Wyle Cop, and overthrew him and shattered his arm in several places, and he was carried home in such plight as threw his affectionate wife into such agony as deprived her of life by a disorder arising from the grief she suffered from his illness—even in that accumulation of sorrows his presence of mind and affectionate care never for a moment ceased; and whilst his face was suffused with sweat from the extreme agony he was suffering from the bone of his arm having to be *again* broken by the surgeon—even then he took upon himself the whole preparation for the funeral of his beloved wife, down to the minutest fittings up of the coffin and funeral clothes; and what all his own sufferings could not wring from him, he gave way to with the utmost bitterness when the dead body of her he so much loved was carried into his chamber, that he might kiss it before it was for ever removed from his sight!

As a master he was kind and considerate to all employed under him; his workmen, if they conducted themselves well, became grey, and died in his service. In our obituary last month we recorded the death of John Maybrey, sen., who had been upwards of 40 years in the employment of Mr. Hazledine, who, indeed, reminds us of Addison's character of Sir Roger de Coverley :—"You see the goodness of the master even in the house-dog, and in his *grey horse*, that is kept in the stable with great care and tenderness, out of regard to his past services, though he has been useless several years."

The religion of Hazledine was also somewhat characterised by Addison :—"Nothing is so glorious in the eyes of mankind, and ornamental to human nature—setting aside the infinite advantages which arise from it—as a strong, steady, masculine piety: but Enthusiasm and Superstition are the weaknesses of human reason—that expose us to the scorn and derision of Infidels, and sink us even below the beasts that perish."

A very short time before he was confined to bed by his last illness, a nobleman, equally distinguished by his literary and legal talents, and filling one of the highest situations which a subject can occupy, arrived in the town, at a little before seven in the morning, and inquired at the Lion if Mr. Hazledine was likely to be up?

"Oh yes," was the reply; "he passed here an hour and a half ago, on his way to the foundry."

"I regret that," said his lordship, "for I wanted a few minutes' conversation with him, which I cannot now have; but tell him from me, that Lord —— inquired after him, and is happy to hear he is so well. My belief is," added his lordship, "that William Hazledine is the first practical man in Europe."

PROPOSAL FOR ESTABLISHING A BRITISH ASSOCIATION FOR THE ADVANCEMENT OF THE FINE ARTS.

A knowledge and consequent due appreciation of the fine arts,—the arts which purify and ennoble,—are now observable amongst much larger masses of persons in the metropolitan cities of the United Kingdom, than was the case twenty years ago; and must inevitably go on to augment in a greatly multiplied ratio, as every step gained becomes the means of further advances. In the provinces, too, where there are fewer "appliances and means to boot," the attention of the people to the importance of the fine arts as civilizing agents, and as tending to promote the general good and therefore the general happiness, has visibly increased, and has manifested itself in more than one good result. Still there is a wide field here open for exertion; and so undeniably important is the object to be attained, so vast is the good that would result from spreading a taste for the fine arts throughout the country, and inculcating a love of the beautiful, that no efforts could be too great, no scheme of operations could be too extensive, which should propose to effect it.

Experience shows the advantages which have resulted from the establishment of the "British Association for the Promotion of Science," not chiefly to science *per se*, although these have been great and manifold, but to the people generally: attention has been awakened in the minds of thousands to subjects before unthought of; a spirit of inquiry has been induced: and whole towns innoculated with an admiration of knowledge, and a determination to pursue it, to the exclusion of demoralizing sources of excitement, until then indulged in. Why, then, might there not be formed an association for the encouragement of ART, which, like this, should meet annually at a different town in England, Ireland, or Scotland, and at which meeting painting, poetry, sculpture, architecture, &c., &c., in all their varieties, and with all their ramifications, should form the subjects for the consideration of the different sections. A large and important exhibition of works of art might be collected, and an Art-Union arranged so as to secure the sale of a certain number of them, and thus to ensure the assistance of the most eminent artists, by rendering the society directly as well as indirectly advantageous to them. A small subscription (say of one pound) would constitute a member of the association for the year, the aggregate of which, after deducting the expenses necessarily incurred, would probably enable the committee (which should be partly local, partly general) to offer prizes for competition in the higher branches of the various arts, and vote sums for the encouragement of any desirable object, in connexion therewith; such, for example, as for the prosecution of experiment in the preparation of colours, the manufacture of stained-glass, or for the purchase of particular pictures, worthy of national regard.

During the meeting the various local collections would be thrown open to inspection: conversazioni would be held; and other means adopted to bring men into contact with each other, on one common ground. One of the first points to be achieved by the united sections would be, to obtain an able and correct report of the progress of Art in England, Ireland, and Scotland, for the last fifty years—a task to be fulfilled satisfactorily only by the joint co-operation of men in all parts of the country. This report would afterwards be continued from year to year, under its various heads, and could not fail to prove a work of the highest interest and value. It is not here attempted, however, to point out what *could* be done by a society organized on the footing suggested: its power of effecting much good must be apparent to all, and needs hardly to be insisted on. The writer is contented simply, but with great earnestness and but one object, namely, strong desire to serve the cause the Art (the cause of morality and public good), to state the proposition, in the hope that others of more ability, influence, and leisure, may view it as it has appeared to him; and be induced to carry it into execution, efficiently and forthwith.

George Godwin, Jun.

Pelham Crescent, Brompton,
January, 1841.

WOOLF'S DOUBLE CYLINDER ROTARY ENGINE.

Sir—In your number for December last, I read a very interesting account of the communication made at the annual meeting of the Manchester Geological Society, by Mr. William Fairbairn: Mr. Fairbairn paid a just tribute of praise to the late Mr. Woolf, by acknowledging the real services rendered by his single engine in Cornwall particularly, and to science generally, in consequence of the undoubted progress made by his application of high pressure steam employed expansively. Mr. Fairbairn's remarks were the more gratifying, inasmuch as the exertions of Mr. Woolf appear generally to be in a state of perfect "oubli," although there can be very little doubt, that he was the first after Mr. Watt to give an impulse to the progress of the Cornish engine, and that much more is due to him than has been generally acknowledged, this circumstance reflects honourably on Mr. Fairbairn's proceeding, to whom much praise is due for his just observations, and for bringing before society a name that is little known, and more honoured abroad than at home.

The principal object of my present application to you is to request, that you will give place to the following observations relative to Mr. Woolf's double cylinder rotary engine, which being but little used in England, has been hitherto very much neglected. I am of opinion that this engine, if better known, and if patronized by engineers of enterprising genius, and in "good repute," would very generally be preferred to every other known system: I speak after having had long and solid experience, and having been in the habit of actual observation abroad, on many hundreds of engines upon different systems, I can very confidently assert, that Woolf's engines when properly made, will work quite as well as any other engine, and will perform the same duty with a consumption of coal that will not exceed *five pounds* per horse power per hour: I have seen many engines of this description doing very satisfactory duty with less.

I have had several opportunities of conversing with manufacturers, who having had low pressure engines, have contracted with engineers to have their cylinders and boilers replaced for the purpose of applying Woolf's principle, and they have invariably declared that they have effected a saving of upwards of one half of the fuel.

I will cite for example an engine on Woolf's principle erected in a mill for rolling zinc and lead, and for drawing pipes. The dimensions of this engine were as follows.

Area of small cylinder, 207·39 square inches.
Stroke of small piston, 4·59 feet.
Speed of piston per minute, 176·34 feet.
Area of big cylinder, 660· square inches.
Stroke of big piston, 6·3 feet.
Speed of piston per minute, 242· feet.
Pressure of steam in the boiler tending to escape into the external atmosphere, 40 lb. per square inch.

The capacity of the small cylinder naturally determines the quantity of steam that the boiler must supply, and allowing that the cylinder fills with steam of an elastic power equal to that in the boiler, and admitting that the big cylinder produces the same effect as the cylinder of an ordinary low pressure engine, the total power of the above engine may be computed in the following manner.

Area of each cylinder in square inches, × pressure of steam per square inch, × speed of piston in feet, and the product divided by 33000 lb. one foot high per minute per horse power, will give the computed power of each cylinder.

$$\text{Small cylinder } \frac{207{\cdot}39 \times 40 \times 176{\cdot}34}{33000} = 44{\cdot}32 \text{ H. P.}$$

$$\text{Big cylinder, } \frac{660 \times 10 \times 242}{33000} = 48{\cdot}40 \text{ H. P.}$$

Computed power of the engine	= 92·72 H. P.
If we deduct for friction one-third	= 30·92
The effective power will be	= 61·8 H. P.

I will call her a 60 horse engine.

To ascertain the quantity of coal this engine will burn, it will be requisite to determine the quantity of water that must be evaporated, to produce a sufficient supply of steam, which can be done as follows:

$$\frac{\text{The area of the small cylinder in sq. inches} \times \text{by the speed in feet}}{144} =$$

capacity of small cylinder in cubic feet per minute.

$$\frac{207{\cdot}39 \times 176{\cdot}34}{144} = 254 \text{ cubic feet,}$$ representing the space occupied by the action of the piston in one minute, and if we add thereto one-tenth for the steam ways, and the space between the top and bottom of the cylinder and the piston, we shall find that the boiler must supply per minute, $254 + 25{\cdot}4 = 279{\cdot}4$, or say 280 cubic feet of steam, under a pressure of 40 lb. per square inch, and per horse $280 \times 60 = 16800$ cubic feet of steam.

One cubic foot of water converted into steam of an elastic form equal to 40 lb. per square inch, will occupy in the shape of steam about 520 times the original volume, consequently the 16800 cubic feet of steam that will be requisite per hour, will be the produce of $\frac{16800}{520} =$ 32·31 cubic feet of water per hour.

$$32{\cdot}31 \times 62{\cdot}5 = 2020 \text{ lb. avoirdupois.}$$

Suppose 1 lb. of coal to evaporate 8 lb. of water, and Messrs. Parkes and Wicksteed have proved that more can be done, but allowing 8 lb. as a fair proportion, the hourly consumption of coal would be

$$\frac{2020}{8} = 252{\cdot}5 \text{ lb. of coal per hour,}$$

$$\text{and } \frac{252}{60} = 4{\cdot}2 \text{ lb. of coal per hour per horse power.}$$

I am aware that nothing in the above computation has been allowed for leakage by the piston, but with a good and true cylinder, and a well fitted piston, very little steam will pass—and if 5 lb. of coal are allowed instead of 4·2 as above, the difference will more than compensate for any loss of this kind.

The above engine was for a considerable length of time doing only 40 horses work, and her average consumption of coal was 1 hectoliter, or 80 kilogrammes of coal of a medium quality per hour, or 2 kilogrammes per hour, and per horse power—2 kilogrammes = 4·41 lb. avoirdupois.

Should you consider these remarks to be worthy of a place in your very useful Journal, you will much oblige,

Your very humble servant,

London, Jan. 11, 1841. H. H. E.

Important to Builders and others.—It may not be generally known that an Act of last Session imposed certain restrictions on the mode of building chimneys, with the view of rendering climbing boys unnecessary in cleansing flues. It is thereby enacted that after the passing of the Act, "all partitions between any chimney or flue shall be of brick or stone, and at least equal to half a brick in thickness," such partition to be of sound materials, "and the joints of the work well filled in with good mortar or cement, and rendered or stuccoed within;" "that such chimney or flue in any wall, not being a circular chimney or flue 12 inches in diameter, shall be in every section of the same not less than 14 inches by 9 inches." The angle at which it is lawful to build any chimney is also determined. Another clause enacts "that from and after the first day of July, in the year 1842, any person who shall compel or knowingly allow any child, or young person under the age of twenty-one years, to ascend or descend a chimney, or enter a flue, for the purpose of sweeping, cleansing, or coring the same, or for extinguishing fire therein, shall be liable to a penalty, not more than ten pounds, or less than five pounds."

LIVERPOOL DOCKS.

Sir—I beg to forward the annexed extract from the "Liverpool Standard" newspaper for insertion in your valuable Journal. My reasons for so doing are:

1st. From personal respect to the talented engineer whose name it bears.

2nd. That the very important document may be preserved, and read by the greatest possible number of individuals at all interested in similar matters. Such documents are very scarce, and very probably this would not have existed, but for the *very extraordinary circumstances* which *demanded* such in defence.

3rd. As a beacon to others, shewing the necessity of always being prepared for similar attacks.

And lastly. To just drop a hint to all the eminent engineers, whether British or Foreign, who may have examined the important works at the Liverpool Docks—works which have been "designed and constructed by the energies of his (Mr. Hartley's) own mind alone, unaided by the designs, arrangement, or superintendance of any other civil engineer." I say just a hint to such persons, that they may lose no time in committing their opinion of the works in question to paper, and forward them to you for insertion in your Journal.

When little dogs bark, it is best to walk away and heed them not; but when great dogs bark and shew their teeth, (especially when they want a bone with a little flesh on it to pick,) there is great danger of their biting; then is the time for defence.

Your insertion of the above, together with the annexed defence, will oblige

Your obedient servant,
A Lover of Fair Play.

Warrington,
1st Jany., 1841.

"To the Chairman and Members of the Dock Committee.

"Gentlemen,—I feel called upon, not only as a mark of respect to those various gentlemen who have composed the Dock Committee during the sixteen years I have had the honour to fill the situation of Dock Surveyor, but also in justification of myself, to make some remarks on the notice of a motion given by Mr. Chapman, at the last meeting of this Committee, as well as to the charges brought against me by him in so abundant and unqualified a manner, both previous and subsequent to his giving notice of that motion.

"It was, I believe, and I do not wonder at it, a subject of surprise to many, that I did not say more in my defence. It was not, however, from a deficiency of matter, but from an overpowering feeling of astonishment at the sudden and unqualified torrent of assertions, charging me with incompetency, incorrect statements, &c., with which I was assailed.

"Had I only to reply to the individual member who made these charges, I might think it proper to take a different course, and should probably simply refer him to the books and resolutions of this committee; but as his charges reflect not only upon me, but upon this committee, upon those who composed the committee before you, as well as upon those who elected me to the office I hold, I think I am bound to rebut them, in doing which I anticipate little difficulty.

"In the first place, I am charged with incompetency and ignorance of my profession, upon which is founded the motion, 'That a first-rate engineer be appointed, to furnish designs for new works, and superintend their construction.'

"In answer to this charge, I will not refer you to the testimonials which procured my appointment to this situation from amongst numerous candidates, without my having had any previous knowledge of any gentleman forming the then council; but I will refer you to those important works which I have constructed since I have filled the situation I hold, from my practical knowledge as a civil engineer, and from the energies of my own mind alone, unaided by the designs, arrangement, or superintendence of any other civil engineer, and which, I may be allowed to say, so far from being considered evidences of *incompetency*, have elicited the admiration of civil engineers of the highest standing, both of our own and foreign nations. I will also refer you to the proceedings of the Dock Committee since my appointment, and during the progress of those works, and I will ask the member who has brought forward these charges, whether he has found in those proceedings (which, of course, he made himself master of before bringing such charges) any resolutions accusing me, in the most remote manner, with incompetency, or casting the slightest stain upon my character? and I will ask him further, to mention an instance in which those interested in the working of the different designs I have furnished and executed, have made a complaint of the inefficiency of those designs, or of their construction, to this committee, until his becoming a member of it, and bringing forward objections against a work, the first of the kind yet executed here or elsewhere, which had been in progress for several months, which had received the approbation of the authority next to be consulted by me after the committee (I allude to the Master of the Graving Docks), and in which, on the 31st July, when partly completed, one of the large steam ships was docked, shored, and the necessary work effected, without a complaint having been made, or an objection offered?—a practical proof of its *not being unsafe for life or property*.

"With reference to the several assertions made by the member concerning this graving dock, which have gone through the newspapers before the public—'That if the large steam-boats, for which this dock was expressly constructed, went into it, their paddle-boxes rested on the quays, and their keels did not touch the blocks by 14 inches,' and also, 'that the sill had been broken up'—I would beg, in the first place, to observe, that the extreme width of the largest steam-ship that has yet come to this port (the President), is, according to the dimensions furnished me, 66 feet 8 inches from outside to outside of paddle-boxes,—whereas the width of the graving dock, from the edge of one quay to that of the other, is 71 feet 6 inches, which proves that the paddle-boxes *could not touch the quay by 2 feet 5 inches on each side*, and secondly, that the *sill* of the dock *has not been altered*. The alterations alluded to by the member, which caused the taking up of the masonry, was an improvement in the original design, but no error, and was totally unconnected with the sill, and partly composed of the original masonry of the former graving dock which had not previously been touched.

"From the blame of having neglected to procure the dimensions of the largest steamers until the work was so far advanced, I think the chairman of this committee can fully exculpate me. With regard to the allusions made by the member, to the south graving docks and Coburg Dock, I have to observe that those matters have been previously canvassed,—but it may be as well to state here, for the information of all, that what the member blames me for, concerning the south graving dock , is what was expressly contemplated in their construction, viz., the increased depth of their silts, to admit of the admission of the heaviest ships coming to the port, at a lower tide than the old graving docks would permit; but if vessels are allowed to be taken in by the carpenters at all tides, it cannot be expected, by any who have paid attention to the tides here, that a sill lying 2 feet 6 inches below the level of the old dock sill, can be laid dry at a low neap tide, which does not ebb within a foot of the level of that datum, unless recourse be had to mechanical assistance. And as to my desire to put reverse gates to the passage leading into the Coburg Dock, that was *an addition to*, but certainly not an alteration of, or error in, my original design; neither did I report 'that the dock was complete, after which it was found that it required deepening,' as asserted by the member, my report to the committee being as follows:—'The Coburg Dock has been completed, *excepting a portion of its bed, which is not yet sufficiently deepened*, but is expected to be all finished in September, chiefly with dredging machines,' and that report would have been borne out, had it not been from the desire to afford the earliest accommodation to the large steamers which have since almost continually occupied the dock, often greatly to the hindrance of the dredging machines.

"I will also beg leave to mention, that so far from my having been considered incompetent by others, I have at various times been requested to exercise my profession in similar and other works, both here and in several other parts of the kingdom; and I may also remark, in noticing the second portion of this motion, that although the terms of my appointment gave me full liberty to exercise my profession elsewhere, yet so closely have I devoted my time to the dock works, as not to allow myself any leisure to accept other engagements, excepting such as my son's assistance enabled me to do, without requiring any lengthened absence from the duties of my situation; and I would wish the member to name any instance in which I have heretofore been accused of non-attendance to, or neglect of those duties; indeed, so far has the contrary been the case, that during the last three years I have not been in the whole more than 15 days absent on private business, and the most of those days I have been but partially absent. In concluding my notice of these charges, I would beg leave to call to your remembrance the circumstance of my having been presented with the freedom of this town *as a mark of the Council's approbation of my conduct as Dock Surveyor*.

"The other charges made against me by the member, and the implication contained in the first part of the motion given notice of, backed as it was by many assertions of impropriety in the expenditure of my department, need not, I think, require any lengthened refutation. With regard to the first of these, personal attacks of this description are easily made on any one filling a public situation, and however unjust they may be, cause great annoyance to those unfortunately subjected to them. In the present case the effect ceases there. I have been too long a public servant here and elsewhere, too long open to the scrutiny of all, to feel afraid of my character suffering from any assertion or observation the member can or has made; and I shall content myself with simply assuring this committee, that in all my statements to them I have invariably adhered to what I have believed to be the truth.

"As respects that part of the motion, stating an increased vigilance in the superintendence of the expenditure in my department to be necessary, taken in the abstract, I have nothing to say against it; on the contrary, too great a vigilance cannot be had to please me, as it will consequently, in like proportion, relieve me from care and responsibility. But taking this part of the motion in the spirit in which it is brought forward, and coupling it with the personal allusions made in bringing it before you, I should have considered it the most serious part of the attack upon me, and should have felt great anxiety to have disproved it most fully, had it been made by any gentleman of experience in the proceedings of the Dock Committee; but when I recollect that it is made by a member who has but recently joined the committee, and who has not yet given himself any opportunity of inquiring into the manner in which the expenditure he alludes to, in my department, is made, never having yet been to my office to ask any explanation or information as to our accounts or method of business, I think it best to refer it to your own judgment, what foundation he has for his assertion, 'that at least a saving of £10,000 a year may be made in my department, *by a different method of carrying on the work*.' I feel, therefore, very easy in leaving my character in your hands, to most of whom I have been known so long, and under whom, until now, I have filled my situation free from all ungenerous attacks or uncourteous treatment. In concluding, I beg leave to quote the following extract from the printed copy of the Inquiry into the affairs of the Corporation of Liverpool, before the Parliamentary Commissioners—'Twelfth day. Mr. Alderman Lawrence said, he was glad to find it was not considered necessary to put any questions to Mr. Hartley, the Dock Surveyor; as an expenditure of £1,400,000 or £1,500,000 had passed through that gentleman's hands, he deemed that circumstance highly complimentary. Mr. Duncan said, he did not know a more deserving officer than Mr. Hartley; the rate-payers were perfectly satisfied with him,' &c.—and to remark, that that opinion, unqualified, uncontradicted, and expressed at such a time, is not exactly in accordance with the member's statement, 'That you will find you have spent as much money in rectifying my errors as the docks themselves have cost.'

"Finally, I take the liberty of calling your attention to a resolution of the Dock Committee of the 31st October, 1836, come to on the reading of my report to them of the 25th of the same month, and to that report I would beg especially to refer the member bringing forward the motion:—

"At a meeting of the Dock Committee, 31st Oct., 1836, present, Charles Lawrence, Esq., chairman, &c. &c., a printed copy of the Surveyor's report having been laid upon the table, in compliance with the directions of the last committee—

"'*Resolved*,—That the committee have read with much satisfaction the able report of the Surveyor upon the state of the works, and regret that, from the shortness of the time since which this report has been delivered, they are not able to enter into any minute investigation of its various details. They feel it quite unnecessary to express any encomium upon those magnificent works which will speak for themselves, and remain a lasting memorial of the great talents of Mr. Hartley. The major part of this committee being about to be removed by an act of the legislature, cannot relinquish their trust without availing themselves of their last meeting to record their high sense of the indefatigable zeal and great ability with which that gentleman has for more than twelve years executed the very important duties of his office, and they beg him to accept their sincere acknowledgments and thanks.

"'Extracted from the proceedings.

(Signed) "'Charles Lawrence, Chairman.'

"Having thus disposed of such of the charges and assertions made by the member as I think it necessary to notice, I feel that it would be an act of injustice to this committee to court a stricter investigation of the various details of my department than they have already received; and the unimportance of the charges which have been made ought, I imagine, to have been a sufficient protection against such an attack as I have been subjected to. If not, the further defence must rest with the committee, not with me.

"It now only remains for me most respectfully to request this committee to do me the justice of calling upon the member to prove his assertions, so serious in their nature, and to hope that this defence may meet with the same publicity as was given to the charges against me.

"I have the honour to be, gentlemen,

Dockyard, Liverpool, Jesse Hartley, Dock Surveyor.
10th Dec., 1840."

RAILWAY COMMUNICATION WITH SCOTLAND.

Third Report of Lieutenant-Colonel Sir Frederick Smith, of the Royal Engineers, and Professor Barlow, to the Treasury, in pursuance of the Addresses of the House of Commons of the 14th and 20th August, 1839.

Railway Committee Office, James-street. Buckingham-gate, 14th Nov. 1840.

Sir—The report which, in obedience to the instructions of the Lords Commissioners of the Treasury, dated the 26th of November, 1839, we had the honour to transmit to you on the 16th May last, respecting the competing lines for a railway communication between London and Glasgow, contains a distinct expression of our opinion, that of the three projects which had been submitted to us for that portion of the distance which extends from Lancaster to Carlisle, the preference was due to the project brought forward by Mr. Larmer, for a railway up the valley of the Lune, and by Orton and Penrith.

We, however, observed that this line would not extend to the district of Kendal the benefits of railway communication; and being aware that this thriving town would not only afford great support to any railway passing near it, but at the same time derive important advantages from such a mode of transit, we had directed the attention of the surveyors to this subject, and suggested the expediency of fresh surveys being made, in order to ascertain the practicability of uniting Mr. Larmer's project by the valley of the Lune with that of Mr. Bintley by the valley of the Kent, so as to carry the line within a short distance of the town of Kendal.

It appears that nearly at the period when our report on these northern lines was forwarded to you, some gentlemen connected with Kendal, and who are very desirous of carrying a railway near to that town, employed Mr Larmer to re-survey the valleys of the Lune and Kent, and to examine the ground which separates these rivers to the north of Kendal. The result is, that this gentleman has considerably modified and improved that part of Mr. Bintley's line which is to the south of Kendal; he has also made some slight alterations in that part of his own line lying between Orton and Low Borrowbridge; and he has laid before us a plan and section for a line to be formed through the pass which intervenes between the Grayrig Fell and the Lambrig Fell, and connects the valleys of the Lune and Kent.

Mr. Larmer terms this new line the "Grayrig Junction," and, for the sake of distinction, we shall give the title of the "Grayrig Line" to the whole project on which we are now about to report, pursuant to the instructions we had the honour to receive from you, dated the 29th May last.

The two principal points which we have kept in view in this investigation are, to determine how the construction of the railway, according to this combined project, would affect the traveller between London and Carlisle; and secondly, whether it would entail an increase of expense more than commensurate with the advantages to be derived from the line passing the town of Kendal.

In our last report, we stated that the locomotive power requisite to work the Lune line, expressed in horizontal distance, would be 78 miles and one chain; and we find, that by the Grayrig line it would be 78 miles and 62 chains.

This increase of 61 chains is not sufficient to form an important objection to the Grayrig project, as regards the traveller between London and Carlisle.

In the appendix (A) we have given a copy of a comparative estimate, submitted to us by Mr. Larmer, of the probable cost of the Lune line, and the Grayrig line.

As we are not in possession of cross sections of the ground where the heavy cuttings and embankments would be formed, nor of borings where the former would be necessary, and as we have also not been supplied with drawings of the bridges, viaducts, &c., it is not in our power to pledge ourselves to the positive accuracy of these estimates; but we think the details given are sufficiently correct to test the relative cost of the two projects; and there does not appear to be any reason for doubting Mr. Larmer's statement, that the Grayrig project would not require a capital of more than £126,219, 7*s*., beyond what would be necessary for that of the valley of the Lune.

In our former report on the lines between Lancaster and Carlisle, in estimating the population within ten miles of each route, the population of Kendal was considered as belonging both to the line of the Kent and to that of the Lune; and, according to this arrangement, the former was stated to be likely to afford railway accommodation to a population one-tenth larger than would derive this advantage from the latter.

The Grayrig line would accommodate a still larger number of persons than the original line of the Kent, as it would include the greater part of the population which gave the latter, under this head of comparison, the superiority over the original Lune line, and in addition would include the inhabitants of Ravenstonedale, Kirkby, Stephen, Brough and Appleby, to which the original Kendal line had no title. Thus the Grayrig line will have a decided superiority over the line of the Lune on the score of population, and therefore the traffic on the former, on this account alone, might reasonably be expected to be greater than on either of the other lines; but when it is considered that a line to Kendal would bring the lake tourists to within eight miles of Windermere, it may be fairly presumed that the number of passengers on this line would be much greater than on its competitors.

Kendal, as a commercial and manufacturing town, is of great importance in the county of Westmoreland, and there is no doubt that on the formation of a railway by the Grayrig Line, the supply of coal for the Kendal district would be almost exclusively derived from Carlisle; indeed it has been shown to us that a revenue of £10,000 a year may be expected from the carriage of coal alone.

In considering the relative merits of the three projects, we find that the Lune line has a small addition over the other lines in regard to saving of distance and economy of construction, but it has the defect of depriving the important town of Kendal of direct railway communication, and embraces a smaller population.

The great objection to Mr. Bintley's line was a summit tunnel of an almost impracticable character.

The line now proposed possesses the principal advantages, and is free from the chief defects of the other projects, and we therefore recommend it in preference to either.

We shall now proceed to give a general description of the line which we thus recommend for adoption.

In our report of the 16th of May, it was stated that Mr. Bintley proposed to form a junction with the Preston and Lancaster Railway, at a point about two miles and 54 chains south of the terminus at the latter place, and to pass under the town of Lancaster by a tunnel.

Mr. Larmer in commencing at the Lancaster terminus, very materially improves this line, as he thereby saves two miles, and 54 chains of construction, and avoids the inconvenience and expense of a separate station; and by keeping to the east of the line proposed by Mr. Bintley, he is enabled to dispense with the tunnel under the town of Lancaster, which was a great defect in Mr. Bintley's project.

The following table exhibits the gradients on the two lines up to Kendal, from which it will appear that the line as revised by Mr. Larmer is in that respect superior to the original line of Mr. Bintley.

Mr. Bintley's Original Line.

Miles.	Chains.			
1	16½	fall	1 in 133	REMARKS.—Commencing at the distance of 2 miles and 54 chains south of the London terminus.

3	75½	rise	1 in 181	
2	72	..	1 in 153	
22	34			

Mr. Larmer's improvement of Mr. Bintley's Line.

Miles.	Chains.			
1	35	fall	1 in 200	REMARKS.—Commencing at the Lancaster station.
3	62	..	1 in 660	
2	50	level		
2	7	rise	1 in 160	
4	16	level		
1	76	rise	1 in 170	
3	—	..	1 in 160	
1	23	..	1 in 150	
20	29			

Although the gradients are in a slight degree more favourable according to the line as altered by Mr. Larmer, yet the cost of the earthwork will be rather greater, and Mr. Larmer will require a more expensive bridge for the crossing of the Lune, for its length will be about 600 yards, and its height 60 feet; whereas the bridge proposed by Mr. Bintley would not be above one-fourth of the length and one-half of the height of Mr. Larmer's.

However, this difference will be much more than compensated by the saving of the tunnel under the town of Leicester, and by the shortening of the line.

The deviations from Mr. Bintley's line, proposed by Mr. Larmer, are not of sufficient importance to require to be particularly mentioned here.

The direction of the line recommended is shown on the accompanying plan, by which it will be seen that it is intended to pass along the face of the high ground about a mile eastward of Kendal.

Mr. Larmer's junction line commences at a hamlet to the north of Kendal, called Scalthwaiterigg Stocks, whence it takes a north-easterly course, twice crossing the turnpike-road to the northward of Docker Garths and Mosedale Hall; it then proceeds nearly in an easterly course to the farm at Shaw-end. This point is the summit of the junction portion of the line, and is 562 feet above the level of the sea at low water at Lancaster, or 446 feet above the point of connection with the Preston and Lancaster Railway, the distance being 26¾ miles. Here a cutting will be requisite of two miles in length, in gravel and rock, and of the extreme depth of 52 feet, and of the mean depth of 35. This is the heaviest piece of work on the junction line.

From Shaw End the line tends more to the northward, and curving round the foot of some high ground, approaches the bank of the Lune near Dillicar Park, and converges towards Mr. Larmer's original line, which runs almost parallel to the river, up to Low Borrow Bridge.

Althouth the direction of Mr. Larmer's original and improved lines is nearly the same, yet such are the abrupt and precipitous forms of the hills that a considerable difference exists in the levels and gradients.

We subjoin a table of distances and gradients of the entire Grayrig line, and we have only further to remark, that, after an examination of the ground, we have thought it proper to suggest to Mr. Larmer the expediency of occasional breaks in his long gradients, for the purpose of easing the engine on the ascending planes, and of diminishing the earthwork in construction.

We do not consider it necessary to give minute details of the proposed line, as in the annexed copy of Mr. Larmer's report all the most important features of this project are fairly shown.

The heaviest work on the whole line is the Orton tunnel, which Mr. Larmer proposes to make of the length of one mile and 22 chains; but according to the section, in the accuracy of which we have full confidence, it appears that there will be heavy cuttings at both ends of the tunnel, the greatest depth being at one end 95, and at the other 98 feet.*

Now as we doubt the expediency of making a cutting in this instance of above 70 feet in depth, we are of opinion that it would be proper to extend the length of the tunnel to a mile and a half.

*The line of the tunnel in Mr. Larmer's original project was very accurately surveyed by Lieut. H. D. Fanshawe, of the 12th Foot, who reported that the ground was fairly delineated in Mr. Larmer's section.

Table of Gradients of Grayrig Line between Lancaster and Carlisle.

Names of Places.	Intermediate distance.		Total distance.			Feet per mile.	Ratio.
Lancaster........	1	35	1	35	fall	26⅓	1 in 200
	3	62	5	17	fall	8	1 in 660

	5	54	64	17	fall	25	1 in 210
Carlisle.........	6	—	70	17	fall	33	1 in 160

Mr. Larmer acquaints us that, on a careful examination of the Orton Hill, he has every reason to believe that the tunnel would pass entirely through sandstone; and as it would only be 340 feet below the summit of the hill, we have no doubt that this work might easily be completed in three years from the time of its commencement, under the supposition that Mr. Larmer has rightly informed us as to the nature of the rock through which the tunnel is to be formed.

We have the honour to be, Sir,

Your most obedient servants,

FREDERIC SMITH, Lieut.-Col. R.E.

PETER BARLOW, F.R.S.

HENRY AMSINOK, Lieut. R.N., Sec.

Robert Gordon, Esq., M.P., &c. &c. &c.

MEMOIRS OF SCIENTIFIC MEN.

The two following Memoirs are from the Address of the President delivered at the last Anniversary Meeting of the Royal Society.

JAMES PRINSEP, whose brilliant career of research and discovery has been closed by a premature death in the flower of his age, was Principal Assay Master, first of the Mint at Benares, and secondly of that of Calcutta, where he succeeded Prof. Wilson in 1833; he was a young man of great energy of character, of the most indefatigable industry, and of very extraordinary accomplishments; he was an excellent assayist and analytical chemist, and well acquainted with almost every department of physical science; a draughtsman, an engraver, an architect, and an engineer; a good oriental scholar, and one of the most profound and learned oriental medallists of his age. In 1828 he communicated to the Royal Society a paper "On the Measurement of High Temperatures," in which he described, amongst other ingenious contrivances for ascertaining the order, though not the degree, of high temperatures, an air thermometer applicable for this purpose, and determined by means of it, probably much more accurately than heretofore, the temperature at which silver enters into fusion. His activity whilst resident at Benares has more the air of romance than reality. He designed and built a mint, and other edifices; he repaired the minarets of the great mosque of Aurengzebe, which threatened destruction to the neighbouring houses; he drained the city, and made a statistical survey of it, and illustrated by his own beautiful drawings and lithographs, the most remarkable objects which the city and its neighbourhood contains; he made a series of experimental researches on the depression of the wet-bulb hygrometer; he determined, from his own experiments, the values of the principal coins of the East, and formed tables of Indian metrology and numismatics, and of the chronology of the Indian systems, and of the genealogies of Indian dynasties, which possess the highest authority and value. When transferred to Calcutta, he became the projector and editor of the "Journal of the Asiatic Society of Bengal," a very voluminous publication, to which he contributed more than one hundred articles on a vast variety of subjects, but more particularly on Indian coins and Indian palæography. He first succeeded in deciphering the legends which appear on the reverses of the Greek Bactrian coins, on the ancient coins of Surat, and on those of the Hindoo princes of Lahore and their Mahomedan successors, and formed alphabets of them, by which they can now be readily perused. He traced the varieties of the Devanagari alphabet of Sanscrit on the temples and columns of Upper India to a date anterior to the third century before Christ, and was enabled to read on the rocks of Cuttock and Guzeret the names of Antiochus and Ptolemy, and the record of the intercourse of an Indian monarch with the neighbouring princes of Persia and Egypt: he ascertained that, at the period of Alexander's conquests, India was under the sway of Boudhist sovereigns and Boudhist institutions, and that the earliest monarchs of India are not associated with a Brahminical creed or dynasty. These discoveries, which throw a perfectly new and unexpected light upon Indian history and chronology, and which furnish, in fact, a satisfactory outline of the history of India, from the invasion of Alexander to that of Mohammed Ghori, a period of fifteen centuries, are only second in interest and importance, and we may add likewise in difficulty, to those of Champollion with respect to the succession of dynasties in ancient Egypt. These severe and incessant labours, in the enervating climate of India, though borne for many years with little apparent inconvenience or effect, finally undermined his constitution; and he was at last compelled to relinquish all his occupations, and to seek for the restoration of his health in rest and a change of scene. He arrived in England on the 9th of January last; but the powers both of his body and his mind seem to have been altogether worn out and exhausted; and after lingering for a few months, he died on the 22nd of April last, in the 41st year of his age. The cause of literature and archæology in the East could not have sustained a severer loss.

SIMON DENIS POISSON, one of the most illustrious men of science that Europe has produced, was born at Pithiviers on the 21st of June, 1781, of very humble parentage, and was placed, at the age of fourteen, under the care of his uncle, M. L'Enfant, surgeon, at Fontainebleau, with a view to the study of his profession. It was at the central school of this place that he was introduced to the notice of M. Billy, a mathematician of some eminence, who speedily discovered and fostered his extraordinay capacity for mathematical studies. In 1793 he was elected a pupil of the Ecole Polytechnique, which was then at the summit of its reputation, counting amongst its professors Laplace, Lagrange, Fourier, Monge, Prony, Berthollet, Fourcroy, Vauquelin, Guyton Morveau, and Chaptal. The progress which he made at this celebrated school surpassed the most sanguine expectations of his kind patron, M. Billy, and secured him the steady friendship and support of the most distinguished of his teachers. In the year 1800, he presented to the Institute a memoir, "Sur le nombre d'intégrales complètes dont les équations aux différences finies sont susceptibles," which cleared up a very difficult and obscure point of analysis. It was printed, on the recommendation of Laplace and Lagrange, in the *Mémoires des Savans Etrangers*, an unexampled honour to be conferred on so young a man. Stimulated by its first success, we find him presenting a succession of memoirs to the Institute on the most important points of analysis, and rapidly assuming the rank of one of the first geometers of his age. He was successively made Répétiteur ann then Professor of the Polytechnic School, Professor at the Collège de France and the Faculté des Sciences, Member of the Bureau des Longitudes, and finally, in 1812, Member of the Institute. His celebrated memoir on the *invariability* of the major axes of the planetary orbits, which received the emphatic approbation of Laplace, and secured him, throughout his life, the zealous patronage of that great philosopher, was presented to the Institute in the year 1808. Laplace had shown that the periodicity of the changes of the other elements, such as the eccentricity and inclination, depends on the periodicy of the changes of the major axis—a condition, therefore, which constitutes the true basis of the proof of the stability and permanence of the system of the universe. Lagrange had considered this great problem in the Berlin Memoirs for 1776, and had shown that, by neglecting certain quantities which might possibly modify the result, the expression for the major axis involved periodical inequalities only, and that they were consequently incapable of indefinite increase or diminution. It was reserved to Poisson to demonstrate *à priori* that the non-periodic terms of the order which he considered would mutually destroy each other—a most important conclusion, which removed the principal objection that existed to the validity of the demonstration of Lagrange. This brilliant success of Poisson in one of the most difficult problems of physical astronomy, would appear to have influenced him in devoting himself thenceforward almost exclusively to the application of mathematics to physical science; and the vast number of memoirs and works (amounting to more than 300 in number) which he published during the last thirty years of his life, made this department of mathematical science, and more particularly whatever related to the action of molecular forces, pre-eminently his own. They comprehend the theory of waves and of the vibrations of elastic substances, the laws of the distribution of electricity and magnetism, the propagation of heat, the theory of capillary attraction, the attraction of spheroids, the local magnetic attraction of ships, important problems on chance, and a multitude of other subjects. His well-known treatise on mechanics is incomparably superior to every similar publication in the clear and decided exposition of principles and methods, and in the happy and luminous combination of the most general theories with their particular and most instructive applications. Poisson was not a philosopher who courted the credit of propounding original views which did not arise naturally out of the immediate subjects of his researches; and he was more disposed to extend and perfect the application of known methods of analysis to important physical problems, than to indulge in speculations on the invention or transformation of formulæ, which, however new and elegant, appeared to give him no obvious increase of mathematical power in the prosecution of his inquiries. His delight was to grapple with difficulties which had embarrassed the greatest of his predecessors, and to bring to bear upon them those vast resources of analysis, and those clear views of mechanical and physical principles in their most refined and difficult applications, which have secured him the most brilliant triumphs in nearly every department of physical science. The confidence which he was accustomed to feel in the results of his analysis—the natural result of his own clear perception of the necessary dependence of the several steps by which they were deduced—led him sometimes to accept conclusions of a somewhat startling character: such were his views of the constitution and finite extent of the earth's atmosphere, which some distinguished philosophers have ventured to defend. It is not in mathematical reasonings only that we are sometimes disposed to forget that the conclusions which we make general are not dependent upon our assumed premises alone, but are modified by concurrent or collateral causes, which neither our analysis nor our reasonings are competent to comprehend. The habits of life of this great mathematician were of the most simple and laborious kind; though he never missed a meeting of the Institute, or a lecture, or an examination, or any other public engagement, yet on all other occasions, at least in his later years, he denied access to all visitors, and remained in his study from an early hour in the morning until six o'clock at night, when he joined his family at dinner, and spent the evening in social converse, or in amusements of the lightest and least absorbing character, carefully avoiding every topic which might recall the severity of his morning occupations. The wear and tear, however, of a life devoted to such constant study, and the total neglect of exercise and healthy recreations, finally undermined his naturally vigorous constitution, and in the autumn of 1838 the alarming discovery was made that he was labouring under the fatal disease of water in the chest. The efforts of his physicians contributed for a long time to mitigate the more serious symptoms of his malady; but every relaxation of his sufferings led to the resumption of his labours; and to the earnest remonstrances of his friends, and the entreaties of his family, he was accustomed to reply, that to him *la vie c'était le travail;* nay, he even undertook to conduct the usual examinations of the Ecole Polytechnique, which occupied him for nearly ten hours a day for the greatest part of a month. This last imprudent effort ended in an attack of paralysis, attended by loss of memory and the rapid obscuration of all his faculties; he continued to struggle, amidst alternations of hope and despondency, for a considerable period, and died on the 25th of April last, in the 59th year of his age. Poisson was eminently a deductive philosopher, and one of the most illustrious of his class; his profound knowledge of the labours of his predecessors, his perfect command of analysis, and his extraordinary sagacity and tact in applying it, his clearness and precision in the enunciation of his problems, and the general elegance of form which pervaded his investigations, must long continue to give to his works that classical character, which has hitherto been almost exclusively appropriated to the productions of Lagrange, Laplace, and Euler. If he was inferior to Fourier or to Fresnel in the largeness and pregnancy of his philosophical views, he was incomparably superior to them in mathematical power: if some of his contemporaries rivalled or surpassed him in particular departments of his own favourite studies, he has left no one to equal him, either in France or in Europe at large, in the extent, variety, and intrinsic value of his labours. The last work on which he was engaged was a treatise on the theory of light, with particular reference to the recent researches of Cauchy; nearly two hundred pages of this work are printed, which are altogether confined to generalities, whose applications were destined to form the subject of a second and concluding section: those who are acquainted with the other works of Poisson will be best able to appreciate the irreparable loss which optical science has sustained in the non-completion of such a work from the hands of such a master.

DEVELOPMENT OF ELECTRICITY FROM HIGH PRESSURE STEAM.

ON Saturday, the 19th December, Mr. Condie, manager of Blair Iron Works, Ayrshire, performed this new and interesting phenomenon at the above works, in the presence of Ludovic Houston, Esq., of Johnstone; —— Cunningham, Esq., of Carnbrae Iron Works; Thomas Wingate, Esq., engineer; Springfield, and a number of others, who were all highly satisfied with the accuracy of the accounts given by the public press of similar experiments having been made in the neighbourhood of Newcastle, upon locomotive engine boilers. The experiment made by Mr. Condie was upon the steam issuing from the safety valve of two of the high pressure boilers of the blowing engine, and was simply performed as follows:—

The experimenter placed himself upon an insulated stool (a board resting upon three quart bottles in absence of better,) and having in one hand a long small rod of iron, with four sharpened points, similar to a lightning conductor; this he held in the steam issuing from the safety valve. When the points were held about one foot from the valve, electric sparks were drawn by the bystanders' knuckles from those of the experimenter about half an inch long; but as the pointed rod was raised to about six or eight feet above the valve into the cloud of steam, vivid and pungent sparks were then drawn from one and a half inches long, which, in fact, were nearly as stunning upon the arm as the shocks of a small Leyden phial, producing a good deal of merriment to the astonished workmen who were present, to see fire and feel the shocks from steam, an article they all supposed themselves perfectly familiar with.

In the evening the experiment was resumed, to see the effects in the dark, when they proved the experimenter to be highly charged with electricity. The board on which he stood, not being rounded, each corner had a brush of light two or three inches long, like as many tassels, while every point of his dress and hair became highly luminous upon the persons standing near him. On this trial, sparks were drawn fully two inches long, which required some little courage to engage with, from their shocking propensities.

The experiments were made upon the steam of two boilers, thirty-two feet long by six diameter, first with steam equal to 12 lb. upon the inch, and latterly at 25 lb.—the increase of pressure adding to the effect. However, the experiment was perfectly and satisfactorily performed with the surplus steam issuing from the safety-valve while the engine was going upon trial. Mr. Condie is of opinion that, from such boilers, with a properly constructed prime conductor, of large surface, sparks may be drawn from six to eight inches long, and large jars charged in a few seconds. The wonder was that the experiment succeeded at all, as the apparatus was altogether rude. The floor where the temporary stool stood was covered with dust, shavings, &c., which acted as conductors in stealing away the electricity from the experimenter.—*Ayr Observer.*

PUBLIC WORKS IN PARIS.

The *Moniteur* takes a survey of the principal public buildings in Paris and its immediate vicinity, either terminated during the past year, or the works of which have been much advanced. We gather from it the following particulars:—It appears that the interior of the new buildings added to the Luxemburg would have been entirely finisbed but for the interruptions caused by the political trials that have taken place before the Court of Peers. Several alterations have been made in the gardens, and the whole may now be expected to be speedily terminated. Statues or other decorative objects are to be placed on the pedestals of the Pont de la Concorde, to make it harmonize with the present highly decorated aspect of the Place de la Concorde. Nothing but works of ornamentation now remain to be done at the Madeleine. The paintings by Messrs. Abel de Pujol, Schuetz, and Signol have been uncovered in the interior, and the statues that are intended for the several altars are far advanced. The Abbey of St. Denis will still take two years before all the repairs are completely terminated. During the last year the great circular window in the north transept, and the organ-loft, have been finished. The works in the Palace on the Quai d'Orsay are not yet terminated, but the Court of Accounts is expected to move into that building during the spring. The works for new bureaux at the office of the Minister of the Interior, Rue de Grenelle, are rapidly advancing: as are also those at the hotel of the Minister of Public Works, Rue St. Dominique. The archives of the law department are to be removed from the Sainte Chapelle to the new buildings at the Hôtel de Soubise, Rue du Chaume, preparatory to the restoration of the former edifice. An amphitheatre for lectures has been erected at the Observatory, and several buildings have been made at the Veterinary School of Alfort, for giving better accommodation to the professors for their lecture, &c. The buildings of the new Blind Hospital, Boulevard des Invalides, will shortly be entirely roofed in: and the additional erections at the Lunatic Asylum at Charenton are going on rapidly. Numerous public buildings, such as the Bibliothèque Royale, the Bibliothèque St. Geneviève, and the Conservatoire des Arts et Metiers, are in such a dilapidated state, that the Chambers will no doubt vote the funds requisite for repairing them, or erecting new ones.

NEW INVENTIONS AND IMPROVEMENTS.

PAPYROGRAPHY.

This is a new invention for reproducing drawings, manuscripts, and all kinds of designs to an unlimited extent, and by means much cheaper than at present known. This process, which is called by M. de Manne, the inventor, *Papyrography*, is very fully noticed in a late number of the *Moniteur*, from which we abridge the following particulars.—The mode by which M. de Manne produces designs, &c., on paper, is thus described. After having, by means of his prepared metallic ink, traced the drawing on common writing paper, he contrives, by an operation which he at present keeps secret, to make the lines rise from the paper in relief, and become extremely hard and durable. He fixes this matrix on a plate of metal, on which he then places the paper that is to receive the impression. Over the paper he places a piece of silk, and passes it under the roller of a copper-plate press; when the characters and lines on the manuscript or drawing are reproduced, stamped in on the paper. These designs thus fixed on the plates are hard enough to allow of a greater number of impressions being taken without injury to them. The part of the invention, which consists in obtaining plates of metal cast from the matrix afforded by the drawing on the paper, is considered by the committee of the Society of Arts of Mulhausen, who were appointed to examine it, as of still greater importance than any other. By this engraving on paper, say the committee, may be obtained impressions fully equal to what can be had from wood engravings; by this means, therefore, works which require illustrations may be printed with great cheapness. In engraviags on wood, the design and the subsequent cutting are necessary, but by the papyrographic method, the design is the only expense; and it will produce without end as many engraved plates and impressions as may be required, at a cost one-half of that of the usual processes; and with a precision equal to that of the original drawing.—As M. de Manne conducted his experiments at Rouen, where there was no skilful metal founders, he laboured under great disadvantage in his attempts to bring his invention to perfection, but the specimens he sent to the committee were sufficient to convince them that his plan was capable of answering all that he stated. Some of the specimens sent to the committee presented the designs, and the printed copies from them in relief to the height of from two to three millimetres, obtained solely from the matrix traced on paper. The committee propose to extend the invention to the printing of woven fabrics and paper. M. de Manne sent some plates prepared for this object, but owing to the disadvantages under which he laboured, the plates were not so perfectly cast as they ought to have been, to produce the desired effect. The defect, however, he ascribes entirely to the unskilful manner in which the Rouen founders took the cast of his matrices: for not venturing to trust them with the paper moulds, he took casts of them in plaster; from which the metal plates were afterwards cast. It is to this circumstance that M. de Manne attributes the failure of his experiment, as it was difficult to take the cast in plaster from the paper so as to preserve the sharpness of the outline. He says he is certain of the success of his process as applied to the printing of papers and calicoes, but want of means with him, as with many other inventors, prevents him from taking out patents, or from carrying the invention into operation. The committee report that it seems to them highly probable that if the inventor was placed in more favourable circumstances, he would arrive at remarkable and very useful results. In conclusion they recommend the society to grant him a silver medal, though the invention is not of a nature within their usual subjects for prizes.—*Inventors' Advocate.*

BRICKS AND TILES MADE BY MACHINERY.

The French Academy of Sciences lately appointed a committee to examine a machine for making bricks, invented by M. Carville. The following is the substance of their report.—The committee proceeded to examine the action of the machinery in reference to its three principal functions,—of mixing the materials, of moulding the bricks, and afterwards of extracting them from the moulds. The mixing of the clay is performed in a vertical cylinder, by means of an iron axle, to which arms are fixed at different heights, which are furnished with knives. A rotary motion is given to the axle, by the power of a horse, applied to the end of a long lever. The materials are thrown in at the upper end of the cylinder, and when properly mixed, are passed into the moulds, through an opening in the side towards the bottom. Inclined boards, in the form of the sails of a wind-mill, are connected at the lower end of the vertical axle. The pressure resulting from the inclination of these boards constantly pressing against the clay during their rotatory motion, forces it out of the opening; a small vane, formed of iron plates, regulates and restricts the manner in which it issues out. An endless chain, composed of moulds of cast iron, joined to each other by hinges, passes under the base of the cylinder, and the moulds are thus filled with the prepared clay. A heavy roller, of cast iron, begins the compression; it is finished by drawing the loaded moulds through a compressor, composed of two plates of iron, the surfaces of which are not quite parallel. The removal of the bricks from the moulds takes place immediately after the compression, by means of a rammer acting from above. By causing the rammer, during the process, to move in the same direction as the chain of moulds, a continuous action is obtained, by means of very simple mechanism. The moment when the blow of the rammer should be given is very ingeniously determined, by joints fastened to the moulds. This motion, thus derived from the chain of moulds, and acting invariably with it, prevents the inconveniences that would result from the lengthening of the chain, by the inevitable wearing out of the hinges. The adhesion of the earth to the sides of the moulds, is avoided by their being immersed, for half a revolution of the cylinder, in water, with which a vessel placed under the machine is filled.—Two hoppers are introduced in the machinery, before and after the reservoir, where the earth is prepared. They spread in the requisite quantities the fine sand with which they are constantly supplied. One of them spreads the sand before the moulds are filled, upon plates of iron, connected together so as to form an endless chain, which serves as the bottoms for the moulds. The other hopper sprinkles the surface of the bricks before compression. Thus any adhesion of the substance continues to be avoided both with the roller with which the compression begins, with the iron work which completes it, and with the rammer which removes the clay from the mould. For greater precaution, and in order to obtain more regular surfaces, a slight stream of water continually moistens the pressing roller. The bricks are received on an endless chain of iron plates, after they are taken from the mould, by which they are conveyed to the kiln. The power of a single horse, by turning a wheel, prepares and moulds about 1,500 bricks in an hour.—The commissioners, on concluding their report, observed, that they had convinced themselves of the complete mixture of the substances forming the bricks, by breaking and inspecting several of them. They inspected the whole process, and so far as the result of the manufacture was concerned, they express themselves perfectly satisfied. As to the saving to be effected by it, they had no ground on which to arrive at a satisfactory conclusion, so as to confirm the statement of the inventor, who affirms, that for the cost of two frames he can mould a thousand bricks. From their inspection of the working of the engine, they were enabled to think that this statement is correct.—*Ibid.*

NAIL, PIN, AND RIVET MACHINERY.

William Southwood Stocker, of Birmingham, certain improvements in machinery applicable to making nails, pins, and rivets, Jan. 2. Claim first.—Mode of combining the forging tools in a moveable frame, and causing such tools to approach each other and forge a bar of iron that is properly held by a machine, either in making the stems of nails or bolts, or in pointing their ends. Claim second.—Mode of constructing the heading and cutting machine. Claim third.—Mode of applying moveable dies to the machine, for heading pins and rivets. Claim fourth.—The turning over by machinery and cutting a series of plates or strips of metal in making cut nails. A crank axle is mounted in a strong frame communicating by means of pulleys to the engine. Four iron bars are caused to slide backwards and forwards in a frame by a rod from the crank axle. Other sliding bars are placed so as to move in a position at right angles to these. Their ends are supplied with anti-friction rollers, that work against an inclined plane. By these bars the forging tools are moved to their proper places. A tube extends along the machine, one end of which very nearly approaches the forging tools. A red hot bar of iron is passed through the tube: motion is given to the axle, which, through the connecting rod, gives motion to the sliding bars and rollers, causing the forging tools to close together, and their action on the heated bar produces the shanks of bolts, nails, or rivets, of any shape or size. The heading machines are constructed by a cranked axle, working the heading die, which strikes the bolt as it lies in a proper cavity, and forms the head of the nail or rivet. Another machine is shown in which the working parts are the same, only instead of a fixed cavity for holding the shanks previous to the heading, dies are used, one of which is moveable and the other fixed, and are held together by a spring catch and lever. With reference to the last part of these improvements: a pair of shears are worked by the revolution of a crank axle. At the face of these shears a series of cylinders are placed angularly. Through the end of each a strip of metal of the required width passes. The whole of the cylinders are connected by pinions and a rack, so that on the cranked axle being made to revolve, a nail is cut from each strip of metal by a descending cutter. A sliding motion is then given to the rack, which causes the cylinders and pieces of metal to move round sufficiently at every stroke of the cutter, to preserve the angular or taper form of the nails or brads.—*Ibid.*

SUBMARINE PROPELLERS.

John Edward Carpenter, of Toft Monks, Norfolk, improvements in the application of machinery for assisting vessels in performing certain evolutionr upon the water, especially tacking, veering, propelling, steering, casting or winding, and backing astern, Dec. 12. Claim first.—The application os adaptation of submarine propellers, as hereafter described, in whatever situation such propellers may be placed. Claim second.—The peculiar form of the propellers, shown in the drawings annexed to this specification. These improvements may be divided into three parts:—First—The method in which the propelling apparatus is fixed, for propelling vessels at the greatest possible speed attainable, with reference to submarine rotary propellers on the quarter. Secondly—The method of applying the same apparatus, so as to turn vessels about without the assistance of wind or rudder. Thirdly—The method of applying the apparatus to vessels, with one propeller at the stern. The blades and screws forming the quarter propeller may be constructed either of metal or wood, their strength and superficies depending on the size of the vessel which they will have to propel. Spindles are constructed, which consist of moveable axles protruding through the vessel at both quarters, near the line of floatation, below the load-water line and above the keel, between the midship section and the stern frame. These spindles are enclosed by metallic cylinders, or other proper packing, having a cup and socket valve and stuffing-box at one, or both, ends, and are firmly secured to the timbers of the vessel. That part of the spindle which is within the vessel is to be connected to a steam-engine, or other first mover, by any convenient mechanical contrivance. The outer part is connected to the propelling shaft. The regulator consists of a rod furnished with a rack and pinion, with a pendant bearing attached to the propelling shaft at the bottom of the rod. Through this bearing the propeller shaft passes, by which means the propeller can be raised or lowered, as circumstances may require. The end or stern bearing is constructed of metal and bolted firmly into the transom of the vessel, so as to be capable of resisting the force of heavy seas against the propeller, and also of being easily detached. With reference to the second part of these improvements, a bevelled wheel is fitted upon the capstan, and this communicates the motive power to the propellers; there are two pinions which gear with the bevelled wheel. The axle of the pinions are connected with the spindles as above described. The propeller is confined in its position by a stay and other parts of the apparatus. The shaft rotates in a bearing, and can be raised or lowered by means of a topping lift. After the apparatus has been connected with the capstan, it is only necessary to turn that by power, and the head of the vessel will move round. The third part of this invention consists in the manner in which the rudder is divided, so as to admit the shaft of a single propeller to pass through it, and also in the form of the blades to be applied to such shaft. The length of each blade is more than twice its radius, and two of these blades are placed angularly upon the shaft, which is supported by a hinged bearing at its extremity, a strong iron connecting piece joining the rudder at its upper and lower divisions.—*Ibid.*

PLASTER CASTING.

Plaster of Paris is sulphate of lime, or gypsum, deprived of its water of crystallisation by heat. In this state it has such an affinity for water, and is capable of taking up so much, that when the powder is mixed with water till it becomes of the consistence of cream, it sets after a few seconds into a hard mass. In the manufacture of plaster casts, we must pay attention to several little niceties, in order to get rid of all the air bubbles. These arise from two causes, either from the adhesion of the air to the plaster, or from the plaster carrying down air with it, when added to the water. The first is to be remedied by using fresh burnt plaster, which is always adopted by the cunning stereotypers, for they state that if it simply stands a fortnight, the casts will not be so good. The workman cannot explain this, but the rationale was well known to Mr. Wyatt, our celebrated sculptor, who told me that he attributed it to the adhesion of the air; and that thus many delicate casts were injured. He places the common plaster in a saucepan over the fire, and heats it, when it heaves from the discharge of gas, and is then ready for use. Sufficient plaster should be placed in a basin, and water poured upon it till it is completely covered, and all bubbles cease to rise, when it must be thoroughly mixed by rubbing it together. The surface to which it is to be applied should be slightly brushed over with a very small quantity of salad oil. A little fluid plaster may then be poured on the cast, and with a hog's bristle painting brush thoroughly rubbed into all the fine parts, which will prevent the adhesion of any air bubbles in the plaster which might prevent a perfect impression. Another portion of plaster, sufficient to give the desired thickness is now to be added, and time must be given for the whole to set, when it should be removed from the mould, and gently heated to drive off excess of moisture.—*Smee's Elements of Electro Metallurgy.*

PRESERVATION AND STAINING OF WOOD.

M. Boucherie's process, which we have already noticed, proposes to render wood much more durable, to preserve its elasticity, to prevent it from undergoing variations in volume, to which it is liable by dryness and humidity, to diminish its combustibility, to increase its tenacity and hardness, and to give it varied and durable odours and colours. The mode is, to cut the tree at the bottom when it is growing luxuriantly and full of sap. The lower part is then immersed in a trough containing the liquid which it is intended shall penetrate the vessels of the tree. This will reach the highest leaves in a few days. It is not necessary that the tree should be supplied with all its branches and leaves: a few leaves at the summit will suffice. It is not, however, necessary to cut the tree: a niche at the bottom will answer the same purpose, by which the liquid may be introduced. 1. To increase the *hardness* of the wood, and to preserve it from decay, a solution of pyrolignite of iron is to be employed, a substance readily formed by digesting iron filings in pyroligneous acid. 2. To diminish the combustibility, M. Boucherie introduces chloride of lime, or the mother liquor of salt marshes; the wood is thus rendered more flexible. 3. The author also stains the most common natural and indigenous woods. With pyrolignite of iron, a brown colour is produced; with tannin, an inky colour is formed; Prussian blue and yellow tints are afforded by introducing these substances with prussiate of potash, acetate of lead, and chromate of potash. This paper has been very favourably reported on by Dumas, Arago, &c.

FIRE PROOF BUILDINGS.

Louis Lecomte, of Leicester Square, gentleman, for constructing fire-proof buildings. Jan. 9, 1841. This plan consists in the employment of iron frames to receive concrete matters for forming the walls. The basement story of the building is constructed according to the ordinary methods up to one foot or more above the ground; on the basement so constructed is to be erected the patent wall, formed of frames entirely of cast iron, in one or more pieces, or a combination of cast iron and wrought iron plates. These frames are to be set one on to the other until the required height is obtained, the necessary stability being obtained by means of steady pins at the corners of one frame fitting into holes made in the corners of the frame which is opposed to it. Suitable shaped frames are employed for the internal partition walls, and for doorways, window frames, &c. The flues of the chimneys are formed of iron or other metal pipes, placed in the thickness of the walls. When the required elevation is obtained, a concrete of any suitable materials is poured into the framing, and fills up the vacant space, giving firmness and solidity to the structure; a concrete of gravel and lime is preferred. To give steadiness, lead is to be introduced between the joinings of the iron work, in the manner well understood by workers in iron. The doors and window frames are to be fastened to the walls by any of the usual known methods. The main beams and cross beams of floors and roofs may be of cast iron, or formed of iron and wood; or they may be formed of one or more pieces of plate iron, bent up into an oval form, and straightened by an iron or wooden bar passing through them lengthwise, the upper edges of the metal being turned over to increase the strength. In the interval between the beams there are to be iron rods running in various directions, and supporting a metallic wire work, which forms the foundation of the ceiling. Similar wire work is to be employed in lieu of laths for all plaster surfaces. The claim is —1. The mode of constructing the walls of buildings by applying frames of iron filled with concrete. 2. The mode of constructing beams of bent plates of iron. 3. The mode of forming ceilings and other plaster surfaces by the application of wire work in place of laths.—*Mechanics' Magazine*.—[The last claim was adopted in the building of the Pantechnicon, near Belgrave-square. —Ed. C. E. and A. Journal.]

RAILWAY CONFERENCE.

On Tuesday, 19th ult., a general meeting of railway directors and managers was held by appointment at the large room in the Queen's Hotel, Birmingham, at which were present delegates from the following companies, namely:—Birmingham and Derby, Birmingham and Gloucester, Chester and Birkenhead, Eastern Counties, Great Western, Hull and Selby, Lancaster and Preston, Liverpool and Manchester, London and Croydon, London and Greenwich, London and Birmingham, London and Brighton, London and South-western, Manchester, Bolton, and Bury, Manchester and Leeds, Midland Counties, North Midland, North Union, York and North Midland.— George Carr Glyn, Esq., was called to the Chair, and a lengthened discussion took place upon the objects of the meeting. The following is a copy of the resolutions, which were unanimously adopted:—

1.—That in consequence of the public anxiety occasioned by the accidents which have taken place on various railways, the companies here represented, in order to profit by the combined experience of the principal lines, have deemed it expedient that a general conference should be held, for the purpose of taking into consideration the causes and circumstances of such accidents, and the means that may be available of more effectually guarding against their occurrence for the future.

2.—That this meeting acknowledges the grave responsibility which attaches to railway directors, and the obligation under which they lie, to adopt all judicious and practicable expedients for ensuring the general accommodation, comfort, and safety of the passengers entrusted to their charge. That under a strong impression of this responsibility they have assembled on this occasion, and have pursued their deliberations at the present conference.

3.—That this meeting, while it deeply regrets the accidents which have occurred, looks forward with confidence to the beneficial result of unremitting vigilance and habitual caution steadily enforced and established, as the great means of safety to railway conveyance, and accordingly would deprecate any sudden or hasty legislation on the subject; being convinced that the means referred to, aided by such improved arrangements and mechanical adaptations as a more matured experience may suggest, will amply accomplish the desired object.

4.—That the moral character and general fitness of enginemen and firemen, as well as of policemen and other servants, in the correct performance of whose duties the public safety is involved, are so essential to the security of railway travelling, that this meeting recommends to all railway companies the strictest examination into these points; and that it should be a rule more generally adopted amongst different managements, not to employ servants having worked on other lines, without authentic and satisfactory testimonials from their former employers.

5.—That in case of serious neglect of duty on the part of railway servants, it is desirable more frequently to put in force the penal provisions of Lord Seymour's Act, in order that the strictest discipline may be maintained; at the same time this meeting considers it due to men whose services are so arduous, to encourage the requisite discipline and obedience of orders, by adequate remuneration, and by suitable rewards for extraordinary exertions or long sustained good conduct.

6.—That the directors at this meeting assembled have taken into their serious consideration the expediency of placing on the engine a third man as conductor or captain, in addition to the engineman and fireman usually employed; and they are of opinion that such a measure, by distracting attention, dividing authority, and removing or diminishing the responsibility of the enginemen, would increase rather than lessen the risk of accidents to the trains.

7.—That this meeting considers it desirable that there should be a uniform system of regulations and signals recognised as applicable to all railways; and they recommend that the following rules and regulations, with this view, be submitted to the consideration of each railway company.

The following is the code of signals recommended:

Signals by Night.

The *white light* stationary, indicates that all is right; but if waved *up and down*, is a signal to stop; if waved *to and fro*, sideways, to proceed cautiously.

The *red light* is a signal always to stop.

By Day.

The *red flag* is the signal to stop.

The *blue flag* is to stop second class coach trains, luggage, or picking up trains, for the purpose of sending on wagons.

The *black flag* is used by plate layers to indicate that the road is undergoing repair, and that trains must pass slowly.

It is to be understood that *any* flag or lamp, of whatever colour, *violently waved*, is a signal to stop.

[We think it is a great pity that such a great assembly should have taken place to produce such a trifling result. Parturiunt montes, nascitur ridiculus mus. It does appear to us that the directors might have been better employed, or have brought out a more efficient code. The whole affair is quite in the British Association style.—Editor.]

ROYAL POLYTECHNIC INSTITUTION.

We promised ourselves and our readers, last month, a more extensive account of this valuable institution, which we shall now endeavour to give—although, probably, it will be a work of supererogation, as so many of our readers must be either contributors to it, or visitors. The building itself we have sufficiently described on a former occasion, when we gave a plan and engravings of it, so that it now only remains for us to notice some of the many attractions in the exhibition. Going into the Hall of Manufactures, we find a four-horse power double-cylinder condensing engine, by Humphrys, of Lambeth. Entering the gallery of the Great Hall, we meet with one of the first of a series of artistical exhibitions; here you may have your profile taken, go to another artist, and for a trifling fee he models your likeness, this you may have electrotyped, engraved on copper, or lithographed, all in the same establishment. The assemblage of models of planets, on a scale of an eighth of an inch to a mile, is an epitome of the wonders of creation well calculated to suggest serious meditation; the little globe on which we live is dwindled to the proportions of a child's taw, and yet, to place these planets in their due positions, would take a space of seven miles diameter. Long's engine-turning on glass presents old specimens of a standard favourite. Close along side are some of Crace's works in papier maché. In the case marked B are some truly valuable examples from the factory of Mr. Apsley Pellatt, of the progress we have made in the manufacture of glass. We wish we could particularize some of the well-executed ornaments from the Elgin marbles and other antiques. The chess table, painted on slate, in imitation of various marbles, is a very good proof of the skill of the artist, and of the value of the material as a ground for decoration. In case F are some of Mr. Reid's engines. In a side room is a great variety of vases and other works of art, and objects of utility, from the Royal Swedish Porphyry Works at Elfdal, in Sweden. There is only one objection we see to the general use of this stone, and that is the dearness of the articles, which, although they are of everlasting durability, tells upon the pocket. A little encouragement, however, and the proprietors will find means of reducing their prices. Here we may mention the many fine specimens of stained glass by several artists, and of flower painting by Madam Comolera. Now we have spoken of painting on glass, a reviving art, we must call attention to the specimens of wood carving exhibited, which will serve to show that we only want encouragement to revive this also—one by a boy of 9 (No. 438), is promising. Sir George Cayley, with the intention, probably, of competing with Cinderella's Crispin, has deposited, in case H, a pair of slippers, the uppers (we were going to write upper-leathers) composed of glass—these were doubtless the true Cinderella shoon. Elsewhere are some other good specimens of glass weaving. No. 531, &c., are 72 specimens of earths taken in boring a well 220 feet deep at Colebrook Cottage, Islington, showing the difference of the strata at every foot after the first hundred, which were principally blue clay. Osler's anemometer is an ingenious machine, but we should not think works favourably in its present position, as the registering apparatus must be interfered with by the elasticity of the floor, and the moving about of the company. In the lower part of the Great Hall are a number of engines and models, of which it is next to impossible, in our cramped space, to give any account. We must say the same of those relating to marine engineering. In the North-West Sky-light Room is a splendid mosaic table of Swedish porphyry, consisting of nearly 10,000 pieces, and of great weight; the price asked is, we believe, 3000 guineas. Going behind the Great Hall we get into a labyrinth of darkened passages, from which are views of a number of dioramic subjects, among which we must particularly call attention to the Typorama, or model of the Undercliff, in the Isle of Wight. In the West Balcony Room is the porcelain Table des Marechaux, painted by Isabey; five thousand guineas is asked for it, and it is said to have cost twelve thousand, but we fear it will be long before the raffle is filled. Another gorgeous and costly affair is the escriban or cabinet of Margaret of Parma, in the East Balcony Room. Dispersed about are many fine works of art by Mr. Longbottom, and eminent artists.

The best idea we can give of the Polytechnic Institution, is to call it a bazaar of science; you have a number of separate exhibitions and collections thrown into one, you witness the exercise of several arts, you have the use of two lecture rooms, and from the gallery a band converts the halls into a promenade concert, and this morning and evening:—and so with this epitome we shall leave the Polytechnic and its crowded halls to the occupation of our readers.

ENGINES ON BOARD THE "GORGON" AND "CYCLOPS" STEAM FRIGATES.

Fig. 1.

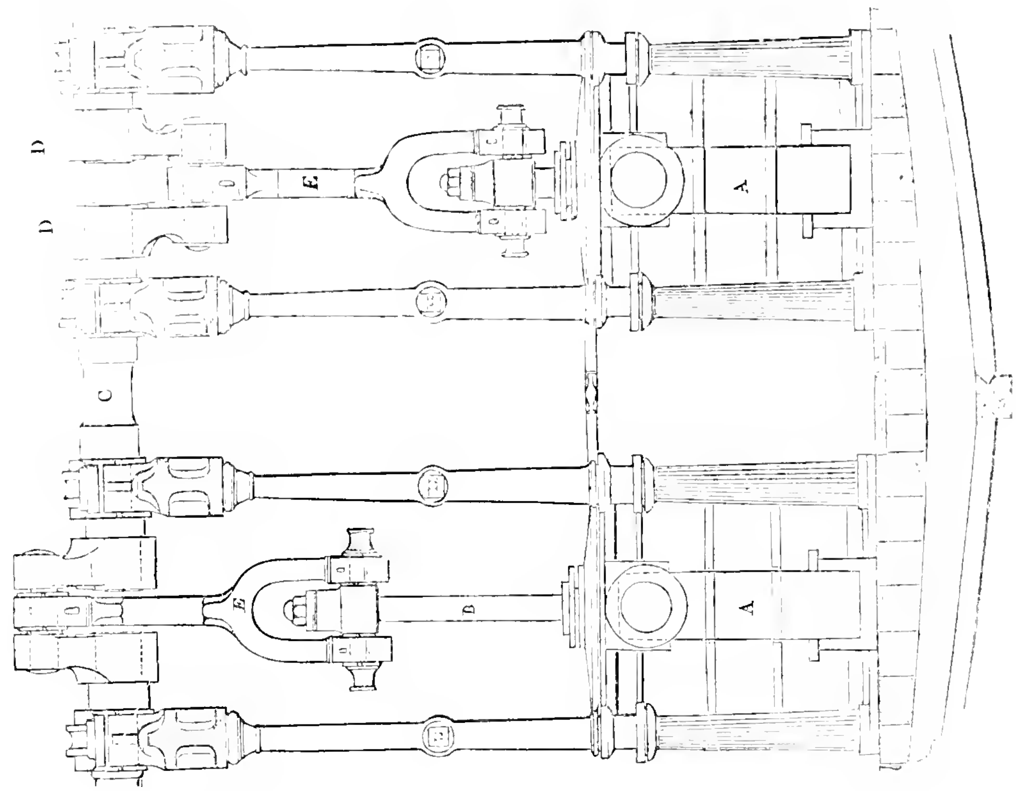

Fig. 2.

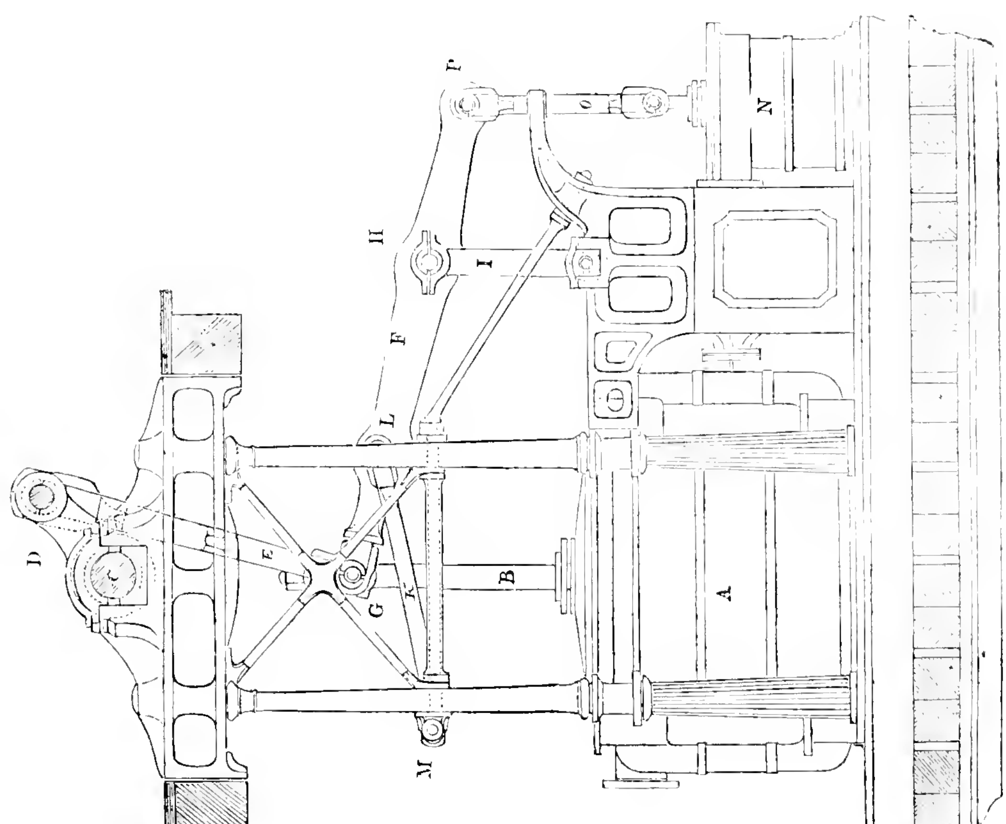

DESCRIPTION OF THE ENGINES ON BOARD THE "GORGON" AND "CYCLOPS" STEAM FRIGATES.

For the following description we are indebted to Mr. John Seaward's pamphlet, from which we have already quoted the two excellent papers "On Long and Short Stroke Engines," and "Long and Short Connecting Rods," published in our last volume; and for the engravings we are indebted to the *Mechanic's Magazine*.

The steam engines which have been supplied by Messrs. John and Samuel Seaward and Capel to the British steam frigates *Gorgon* and *Cyclops*, and to several other large Government steamers, are constructed upon a plan differing materially from those which have hitherto been mostly used in steam navigation; they have been denominated "The Gorgon Engines," from the fact of a pair on this plan having been first tried on board the steam frigate of that name.

These engines are constructed on the principle of what is called the "direct action," that is to say, the power of the engines is communicated from the piston by the piston rod, direct to the crank, without the intervention of those side levers or beams, cross heads, fork heads, and side rods, which are usually employed in the construction of marine engines. The engravings, one being a side view, and the other an end view, will give a tolerable idea of the arrangement of these engines:

A is the cylinder; B the piston rod; C the main shaft; D the crank; E the connecting rod, which connects the top of the piston rod to the pin of the crank.

The top of the piston rod is constrained to move up and down in a perfectly straight vertical line, by the aid of a peculiarly constructed parallel motion. The bar or lever F is jointed to the cap of the piston rod at G, and it also turns or oscillates on the joint or bearing H, which joint or bearing is supported by the rocking standard I; the bar or lever F is retained by a pair of rods K, which are jointed at one end L to the bar or lever F, and at the other end to the fixed centre M.

N is the air pump, which is worked by means of the pair of side rods O, which are attached to a prolongation P of the aforesaid bar or lever.

It will be observed that the distinctive features of these engines are, first, the line of shafts being placed directly over the centre of the cylinders; and, second, the power being communicated direct to the crank without the aid of beams, cross heads, side rods, &c., as before stated.

The line of shafts rests upon strong frames, which are supported by wrought iron columns, standing upon the top of the cylinders: so that the whole force of the engines is confined between the cylinders and the supporting frames and columns, and does not act against any part of the vessel.

It should be observed that many engines have been constructed, previous to the Gorgon engines, upon the principle of the "direct action," but the arrangements of all those engines have been widely different.

The advantages of the present system are very considerable, and consist of:—

1st. *A Great Saving of Space.*—A pair of Gorgon engines do not occupy much more than one half the space required for a pair of beam engines of the usual construction.

2nd. *A Great Saving of Weight.*—The weight of a pair of Gorgon engines is 25 per cent. less than that of a pair of beam engines.

3rd. *Greater Exemption from Accident.*—The simplicity of the arrangements, and the reduced number of moving parts, necessarily lessen the chance of accident, as also the wear and tear.

4th. *Greater Security for the Engine-men who work the Engine.*—There being no side levers or beams in movement, the men can move round the engines in every part with perfect safety; but they cannot do so with beam engines without much danger.

5th. *The Tremor and Vibration usually experienced in Steam Vessels are almost entirely prevented.*—The chief cause of the tremor and vibration observable in steam vessels, is the pumping action of the beams or side levers, which causes a great strain and effort throughout the whole vessel; but there is nothing of this in the Gorgon engines.

6th. *A more efficient and economical Application of the Motive Power*,—resulting from the absence of a large mass of moving matter, and of many joints and bearings, the latter of which especially, is in ordinary engines the cause of *much* loss of power.

The advantages above enumerated will, for the most part, be very obvious, on even a slight examination, by any impartial and competent judge; and of the great importance of the advantages themselves, no one will pretend to doubt for a moment. Indeed, as regards the successful application of this system, the matter is now placed beyond all dispute, as the trials of it, made in the *Gorgon*, *Cyclops*, and several other vessels, during the last three years, have been most satisfactory and conclusive.

REVIEWS.

Pambour on Locomotive Engines. London: John Weale, 1840.

(SECOND NOTICE.)—*(Continued from page 16.)*

In the 11th section it is shewn that on Railways with a wide gauge, like the Great Western, the locomotives have the advantage, at moderate velocities, such as 25 miles per hour, of conveying much greater loads, and consuming less fuel per ton per mile, than on railways with a narrow gauge.

The subject of Adhesion is but superficially treated in the 14th chapter. The adhesion of an engine is not correctly measured by the load *it has drawn*, but by the greatest load *it can possibly draw*, without the driving wheels slipping on the rails, and of this we have no determination; the author has contented himself with shewing, from data furnished by experience, that the adhesive force, when the rails are in good condition, is equal to *at least* $\frac{1}{5}$ of the adhering weight, and, when they are greasy and dirty by the effect of wet weather, it is, except in very extraordinary circumstances, *at least* $\frac{1}{27}$ of the adhering weight.

The limit of the adhesion of an engine might however be deduced from the friction which would result if the engine were dragged along on the rails with the wheels fixed.

Chapter XV. treats of the effects of the regulator, and in the 16th the effects of the lead of the slide are discussed at considerable length.

In the 17th chapter the author investigates in a very clear and scientific manner the influence of inclined planes on the velocity and load of locomotive engines, and deduces therefrom rules which may assist in deciding on the best line to be chosen for a railway between two given points. It is here most satisfactorily proved that the work done in conveying a given load from one point to another is less on a level road than on one consisting of alternate ascents and descents, and that the greater the inclination of the planes, the greater is the amount of work done.

The 18th chapter, on Curves, completes the theoretical considerations of locomotive engines on railways; but it is evident that the author has not given this subject an equal share of his attention, for it is not treated with that perspicuity and just application of science, which characterize most of his investigations. In the 2nd section, when treating of curves of which the resistance is corrected by the conical inclination of the tires of the wheels, he says, page 521,

"The calculation of these effects evidently depends on two things: the intensity of the centrifugal force produced by the motion of the wagons in the curve, and the intensity of the centripetal force produced at the same time by the inequality of the wheels of the wagons."

We are assured that, if M. de Pambour had given a little more attention to this point, he would have seen that the tendency of a cone to roll in the circumference of a circle is not due to any force, but simply to the adhesion of its surface to the planes on which it rolls, which prevents one part from slipping while another is rolling, on account of the friction that would ensue. This tendency does not, however, counteract the centrifugal force: it merely corrects the tendency which wheels of equal diameter would have to roll on in a straight line, and which would thus co-operate with the centrifugal force in causing the carriage to run off the rails. If the effect of the centrifugal force is counteracted by the conical form of the tires in traversing a curve, without the flanches of the outer wheels coming in contact with the rail, it must be in consequence of the centre of gravity of the carriage being raised by its lateral displacement.

The Appendix contains a great quantity of useful information concerning the expenses of haulage by locomotive engines on railways, with Extracts from the Report of the Directors of the Liverpool and Manchester Railway, from the opening of the railway, on the 16th September 1830, to the 30th June 1831.

Notwithstanding the exceptions we have taken to some few portions, the chief part of the work will be found highly instructive, and abounding with valuable data; and the practical tables interspersed throughout will be a great assistance in applying the various formulæ.

The Science of Vision, or Natural Perspective, containing the True Language of the Eye, &c. &c. Second Edition, 24 Plates. By ARTHUR PARSEY, M.B.A.A.S. London, 1840.

Most of our readers, we presume, have heard of that kind of discovery which goes by the name of "finding a mare's nest;" and such it appears to us is that discovery in the laws of optics and perspective on which Mr. Parsey so greatly prides himself; and of whose value he tries to convince us at first sight, by exhibiting a practical application of it in his own frontispiece. In one respect, indeed, that illustration has no novelty, for in nearly every work on perspective we are acquainted with, the subjects introduced as examples, are for the greater part either the most insipid or the ugliest things imaginable, nor does that piece of architecture,—which, by the by, was exhibited a season or two back at the Royal Academy, where it met with a good deal of quizzing,—form any exception to such general rule. It says so little for our discoverer's knowledge of, or taste in, architecture, that he would have acted more discreetly, had he contented himself with *Parseyfying* some building already provided to his hand; nor could he, perhaps, have selected a better subject to operate upon than the front of the Soanean Museum, that being a tolerably whimsical specimen of architecture in itself, and otherwise well fitted for the purpose, inasmuch as its height greatly exceeds its width, consequently it is much better suited to show the convergence of vertical lines, than Mr. P.'s own plump and squat structure.—At all events, as it is intended as a model sample of the new system of Perspective, or "New Language of the Eye,"—a language somewhat akin to Irving's Unknown Tongues,—it would not have been amiss had it been correctly drawn; so far from which being the case, there are hardly above two of the vertical lines that converge to the same point, but some of those that are nearest to the axis of vision are much more inclined than those which are farthest off! which produces the same effect as a drawing in which the cornice or upper horizontal lines of a building should be made to incline less than those of a string-course or lower cornice at half the distance or less, above the eye. It may be that this is an error merely of inadvertence, but then it is a most extraordinary instance of carelessness indeed, because Mr. Parsey must have been aware that his sample drawing would be likely to be rather rigourously scrutinized, and that any blunder in it would consequently be laid hold of as an objection to the system itself. Admitting for a moment his doctrine of the convergence of vertical lines to be correct, his notions of convergence must be exceedingly *eccentric*, for the upright lines of the little stumpy turret on the building vanish much more suddenly than any of the others, so as to give it, even when compared with the rest, the appearance of being a truncated pyramid. We do not know how drawings according to the *vulgar* and now to-be-exploded system of perspective, appear to Mr. Parsey's eyes, but most certainly the one he here favours us with, appears to ours a most preposterously distorted delineation, and totally contrary to nature.

Yes, we are so hopelessly obtuse that all Mr. Parsey's eloquence is quite thrown away upon us when he assures us "This effect of nature *launched incessantly upon the vision of mankind*, as well from *perpendicular* as from horizontal surfaces, has never been recognized by theorists, neither is it found in works of art. It has evidently been a sheer omission." "The necessity of adopting this principle for the future," he goes on to say, "in the visual sciences will require no urging so soon as this truth and its consequences shall dawn upon the unbiassed intelligence of the world."—Which last remark is exceeding well put in, for that dawn seems to be quite as far off as ever. Notwithstanding that so great a luminary as Parsey has risen upon the intellectual horizon, we are as much in the dark as before, or else obstinately shut our eyes and refuse to be enlightened by Parsey's sunbeams.

It certainly is most unaccountable that the very class of persons who are most interested in this notable discovery, and who must of all others be best qualified to appreciate its value, so far from gratefully bearing testimony to its importance—so far from availing themselves of it, are precisely those who set their faces against it, and protest against it with one accord, not indeed, loudly, but assuredly most significantly by refusing, one and all, to make any use of it. When we see one artist—one architectural painter or draftsman begin to adopt it,—when such people as Roberts, Nash, Haghe, &c., whose drawings are in all other respects so admirable, lay aside the old-fashioned, incorrect, vulgar system, and becoming enlightened begin to *parseyfy* their productions, then indeed our own obstinate prejudices may begin to thaw and melt away.

No doubt we are exceedingly dull: our comfort is that we are by no means singular in that respect; for not only have many others altogether scouted the "New Language of the Eye"—which they rudely set down as being All my Eye and Betty Martin,—but neither the Western, the Marylebone, the West London and the Westminster, Literary and Scientific Institutions, "from all of which societies," says Mr. P., "I received most satisfactory and complimentary testimonials," have done any thing as yet to promote and diffuse the new science. Their testimonials may be complimentary, yet if Mr. Parsey considers them *satisfactory*, all we can say is that he is the most reasonable and most easily satisfied person we ever met with. Were the case our own, we should set down the complimentary part of the business, as mere matter-of-course humbug, as being of just as much value as "Your very humble servant" at the end of a letter of refusal. If notwithstanding their professed admiration of the author's theory, people do not care to apply it practically, their testimony in its favour, however complimentarily expressed, must stand for just nothing at all.

With the Institute of Architects—whose testimonial in favour of his system would have greatly outweighed those of merely literary societies—Mr. Parsey was not quite so successful, being peremptorily repulsed, on offering to give "a full and gratuitous explanation" of it to that body. Not satisfied, however, with one repulse, he renewed his application about two years afterwards, when he met with no better success than on the former occasion; as he himself relates at length in his Introduction, where he has inserted the notes he received from the Secretary Mr. Donaldson, and animadverts upon the prejudice and inconsistency shown by the Institute in refusing him permission to demonstrate to them his theory. Yet although he evidently seems to have no suspicion of such being the case, the refusal on the part of the Institute, was probably prompted by kindness, —by unwillingness to let Mr. Parsey not so much explain his principles as expose himself; because the main point of all in his theory, namely, the convergence of vertical lines, must have been tolerably well known to most of the members, it having been made the subject of more than one article in Loudon's Architectural Magazine, where, in fact, it had occasioned some controversy. The Architects undoubtedly knew enough of it, to be aware that it would not at all hold water—as the saying is, and accordingly declined his offer; nor do we think that his frontispiece is likely to gain him any converts in that quarter. Mr. Parsey makes no secret of the repulses he has met with from others, for he speaks of "non-replies to letters addressed to influential scholars,"—we almost wonder he did not address himself at once either to the Premier or the Secretary for the Home Department;—yet although he quotes our friend Candidus, he does not attempt to controvert either what that writer or Kata Phusin have said, fatal as their objections appear to be to his theory, unless they can be set aside; whereas by allowing them to remain unanswered, Mr. Parsey leaves us to infer that he considers them unanswerable.

We have already given it as our opinion that the Frontispiece is not attractive,—otherwise than by its oddity; nor do we think that, its new fangled doctrine apart, the volume itself is calculated for any practical service. On the contrary, it appears to us that Parsey's new light serves only to mystify the subject more than ever—absolutely to bewilder it; and his processes of delineation to be most complex and tedious. To say the truth, there has always been a great deal more mystery made about Perspective, than there is any occasion for, that is, as far as practice alone is concerned, since for that merely a few simple elementary rules are required, and were they but properly explained and elucidated, they would be all-sufficient. The great point of all in teaching the practice of perspective is to convince the learner at the outset, not of its difficulty, but of its easiness, to explain the principles intelligibly, and not only intelligibly, but intelligently also, and to show how those simple elements suffice for all combinations, and for the most intricate subjects. But to come to Mr. Parsey's hobby, or rather his *cheval de guerre*, the Convergence of Perpendiculars—by which we are to understand Vertical lines, we will not be quite sure that Mr. Parsey clearly understands himself, or if he does he has most certainly an unlucky, Mrs. Malaprop way of explaining himself; for an instance clearly demonstrating the natural convergence of perpendiculars, he refers us to the effect produced by looking *up* from the bottom of a deep shaft, or *down* into a well! Good Mr. Parsey, this is playing upon people's credulity rather too openly, for you might just as well have told them not to look into a well nor to walk into one, but to go into the shaft of the Thames Tunnel, and fancy that instead of looking straight before them in a horizontal direction they were looking upwards. Such effects as looking upwards, whether to the roof of "a lofty cathedral" or a low room, cannot be represented except on a horizontal plane over the spectator's head, as in a painted ceiling, for it is only such prodigious artists as Billings who can show us at once the effect of looking up into the lantern in dome of St. Paul's, and down upon the pavement, at the same instant. Except in very particular cases, such as those of ceiling pieces, giving effects of *di sotto in su*, all pictures are supposed to be vertical planes, or planes perpendicular to the horizon, which we therefore view not by looking either *up* or *down*, but straightforward at, and in which no more can be properly represented than can be seen under such angle as will enable the eye to take in at one view the greatest diameter or dimension, whether it be that of height or breadth. And until Mr. Parsey undertook to enlighten the world, both we and all artists, have ever fancied that all lines *parallel* to the picture continued parallel to each other in representation, no matter whether horizontal ones or vertical. Horizontal lines, indeed, generally converge, but then it is because they are situated *obliquely* to the picture; but that vertical lines can be so situated is utterly impossible, for then they would no longer be *perpendicular to the horizon*—that is no longer *upright* lines, but *sloping* ones. Consequently Mr. Parsey's doctrine either goes much too far, or else, does not go far enough. He is either much too daring, or much too timid, and fearful of following up his own principles consistently. He has no objection to say A, but it goes against him to say B. Either he must now give up *in toto* his new law in regard to Perpendiculars, or extend it also to Horizontal lines *parallel* to the picture. There is no other alternative for him; and how so very keen-sighted a gentleman could possibly have make such a "sheer omission" in regard to the last is to us quite inexplicable; more particularly as he himself calls notice to his own oversight—to the unlucky flaw in his doctrine, by remarking that the same laws apply to and govern both Vertical and Horizontal lines, on the strength of which axiom he founds his doctrine in utter opposition to it, referring us to the visible vanishing or convergence of horizontal lines *inclined*, or situated *obliquely* to the picture, in order to convince us that lines perpendicular to the horizon, and therefore *parallel* to the picture plane, ought to converge similarly!! The fact is, Mr. Parsey has built up his fine theory on utter rottenness, and laid the foundation of his notable theory on a mere quicksand.

Here we were just going to lay down our pen, when the thought came across us that *Parseyism* or the new light in perspective, may easily be put to the test by any one, by merely applying it—as through "sheer omission," we suppose, Mr. P. himself has neglected to do—to an interior view of a building, for as the end facing the spectator would by the rules of *Parseyfication*, alias the convergence of perpendiculars, be narrower at top than at bottom, the consequence must be that the sides would *incline forward*. If after this, Parsey's is not allowed to be a complete Mare's Nest, we can only say that John Bull is more of a John Gull than we took him for, and that he deserves henceforth to resign his roast beef, and diet himself upon *moonshine*.

A Practical Detail of the Cotton Manufacture of the United States of America, and the State of the Cotton Manufacture of that country compared with that of Great Britain. By JAMES MONTGOMERY. Glasgow: John Niven, 1840.

Mr. Montgomery is known as the author of the Cotton Spinner's Manual, and the Theory and Practice of Cotton Spinning, both works of established and deserved reputation. The present volume is not less important either to the manufacturer, the mechanic, the economist, or the Englishman who regards the prosperity of his country as connected with its great staple article of export. In the United States we see the country which most threatens our supremacy—our main producer of the raw material, our victor in many foreign markets, and our still more dreaded rival as the introducer of factory slave labour. Under such circumstances, and with the threatening future staring us in the face, this volume before us comes with an equal interest to that which it would ensure from its own merits. Our satisfaction in perusing it has been great, but how to communicate by any extract an equal degree of interest to our readers has appeared to us a task of some difficulty, for it is not easy to detach such a portion of a work so connected as shall do justice to the subject, and at the same time it is, of course, out of our power to give any thing like a sketch which shall include the details of a subject so diversified. We must therefore content ourselves with noting down such remarks as we think may prove most interesting to our readers.

The plan of the Mills, says our author, is nearly the same in the different districts, none exceed five stories in height, except two at Dover (U.S.), which are six stories on one side and five on the other. The general height of the mills is three or four stories with an attic; but the mills recently built at Lowell are five stories high with a plain roof, from which he infers as probable that although the double roof has been the plan generally adopted, that it is likely to be abandoned, as it is the most expensive, and does not give so much room for machinery as the five stories and a plain roof. The mills are generally strong and durable. Instead of joists for supporting the floors, there are large beams about 14 inches by 12, extending quite across from side to side, having each end fastened to the side wall by a bolt and wall-plate: these beams are about five feet apart, and supported in the centre by wooden pillars, with a double floor above. The under floor consists of planks three inches thick; the upper floor of one inch board. Some have the planks dressed on the under side, others have them lathed and plastered; the floor being in all four inches thick, is very strong and lasting. The average thickness of the side walls may be from 20 to 24 inches, and they are generally built of bricks, there being very few stone walls, from the scarcity of freestone.

In England the factories have joists about three inches by ten; these are laid on their edges about 20 inches apart, with one inch flooring above, lathed and plastered beneath, or sheathed with thin boards. The joists are also supported in the centre by a beam about 11 inches by 6, running from end to end of the building; the pillars are of cast iron, and placed right under this beam, which does not rest on the pillar, but on a cast iron case which passes upon each side of the beam, and meets together above, by which means the uppermost floors are supported on columns of cast iron from the foundation; there is therefore no danger of such floors sinking in the centre. In the United States where the cross beams rest on the top of the pillars, while the pillars above rest again upon the beams, the floors in the upper stories sink down in the centre, in consequence of the shrinking of the timber, and the pressure of the ends of the pillars into the beams. Mr. Montgomery says, that he has seen some of these which had sunk down four or five inches in the course of four years.

The mills in England are from six to eight stories high, Stirling and Becktow's mill, Lower Moseley-street, Manchester, is nine stories. The general height of those in Scotland is six stories with a plain roof. In the United States there are few mills driven by high pressure steam engines; four in Newport, one in Providence, Rhode Island, and three in Newburyport, Massachusetts. The coals used whether anthracite or bituminous, cost from seven to eight dollars per ton (30*s.* to 34*s.*) In general the mills are moved by water; and in constructing them the water-wheels are necessarily put under cover, so as to be kept in an atmosphere, considerably above the freezing point in winter, otherwise the severity of the frost, which frequently descends to nearly 30 degrees below zero, would prevent them from operating a great part of the year; hence the water-wheels are generally placed in the basement story, which besides the wheels contains the mechanics' shop and cloth room, or sometimes it is filled in whole or in part with machinery. The English cotton factories generally have their picking or scutching rooms within the mill: but in the United States there are separate buildings erected for these purposes, generally standing like guardhouses about 20 or 30 feet from the main building, with the passages that connect them secured with iron doors, to prevent the communication of fire to the loose cotton in the picking house.

The method of communicating motion from the first moving power to the different departments in the English factories is by means of shafts and geared wheels; but in America it is done by large belts moving at a rapid speed; these are of the breadth of 9, 12, or 15 inches, according to the weight they have to drive, and pass through a space of from 2500 to 3600 feet per minute. A belt of 15 inches broad, moving at the rate of 3000 feet per minute, is considered capable of exerting a propelling force equal to 50 horses' power. All the most recent mills are belted, while many of the older ones have had the shafts and gears removed, and belts substituted in their stead; indeed belts are generally preferred even by those who have had sufficient experience of both. A belt of ordinary size would be between three and four hundred feet long, from twelve to fifteen inches broad, and would require from six to seven hundred pounds of good belt leather to make it. Such belts are always made from the centre of the back of the hide, to that they may stretch equally at both sides. Mr. Montgomery further remarks that however partial American manufacturers may be to this mode of conveying motion to the different departments, those who have been accustomed to the neat manner in which factories are geared in England must regard the above as heavy, clumsy, and inconvenient, as well as more expensive. As all these belts have to be enclosed, they occupy a considerable portion of the rooms they pass through; which, besides interrupting the view, gives less space for arranging the machinery. They are likewise very liable to stretch, and when too slack, they will slip on the drums; and owing to their breadth, it requires a considerable time to cut one joining and sew them up again. As to whether belts have more or less power than English gearing, Mr. Montgomery states his inability to decide satisfactorily; different opinions prevail in America, but there are two mills at Fall River, Rhode Island, which are said to decide the question in favour of the belts.

With regard to the arrangement of the machinery, diversities also prevail. In England the weaving is generally in the lower stories, and the carding and spinning above; but in the States, the weaving is contained in the upper stories, with the carding and spinning below.

Mr. Montgomery next goes on to describe the several classes of machinery used in the States, and to point out the differences from those of England, and here we shall endeavour as far as we can to follow him. The first class is the Willow, in connection with which he says that the American Picker is very injurious to the cotton, and likely to [illegible] The W[illegible] Mr. Montgomery [illegible] called Mason's Willow, which he says is decidedly the best and occupies little room. In the English factories the scutching and spreading Machines are generally two separate machines, but across the Atlantic they are combined into one called the lap spreader, in which they have only one, two, or most three beaters or scutchers, while in England they have generally four or five. There are, says Mr. Montgomery, three most essential processes in the cotton manufacture which, in the factories of the United States are not so well attended to as in those of England. First, the cotton is not so well mixed; second, it is not so well cleaned; and third, it is not so well carded. With regard to the first our author is of opinion that by far too little room is allowed for the picking houses in the United States. Upon carding it is observed that few mills in the States use simple carding, mostly all have breakers and finishers, even those that manufacture the coarsest goods. The average speed of the cylinders there is about 100 to 110 revolutions per minute, there being no carding engines, driven at so high a speed as those in England, or which make work equal to those of the latter country. Indeed the English manufacturers generally make superior work with single carding to what the Americans do with double carding. The work before us says that it is the practice with them to crowd the cotton on to the cylinder so rapidly, that, instead of being taken away from the feeding rollers in single filaments, it is dragged in by the slow motion of the revolving cards in large flakes, which are not allowed to remain long enough under the operation of the tops, to be sufficiently teased out, the doffing cylinder being also driven too fast in proportion to the speed of the main cylinder. In England the practice is directly the reverse: the cotton is led into and delivered from the cards by a very slow motion: that is the motion of the feeding rollers and doffing cylinder, are comparatively slow in proportion to the speed of the main cylinder. For example, a main cylinder 36 inches in diameter will revolve between 70 and 80 times for one of the feeding rollers; in America their motions are as 35 of the former to one of the latter. The proportions of the revolutions of the main cylinder and doffer are in England as 25 of the former to one of the latter; in America as 17 to 1. The mode of stripping the cards adopted in the States is also inferior, as also that of grinding the cards. The drawing process is stated not to be so well performed, and to take twice the amount of labour across the Atlantic. The spinning warps Throstle Spinning Frames are universally used, except in some factories where very fine goods are made. They appear to be worked at a higher speed there, and with advantage, power being cheaper; Gore's Spindle which failed in Glasgow being most successful in the States. In weaving by power Mr. Montgomery considers that the Americans in every respect equal and in some things surpass any thing he has seen either at Manchester or Glasgow, particularly in common power weaving. In fancy weaving however they have not made a beginning. The spooling machine is cited as superior to that used in England, being much more simple, and capable of being attended by girls of 11, instead of women of 30. The warping machine is much the same as here; the dressing machines are entirely different, said to be more simple, more easily attended and kept in order, requiring less power and oil. The Power Looms are generally of improved construction.

We have we trust in this sketch shown enough of the merits of this work, to give a favourable idea of it to our readers, so that we shall conclude by congratulating Mr. Montgomery on this interesting contribution to the literature of a subject so important.

The Railways of Great Britain and Ireland. By FRANCIS WHISHAW, C.E. London: Simpkin and Marshall, 1840.

As we mean to pay several visits to this work, we shall for the present content ourselves with a few extracts, illustrative of the peculiarities of various lines, having in the meanwhile already said enough in our last notice to recommend it to the attention of our readers. Taking up the Aylesbury as the first subject, we find

This railway is laid to the English standard gauge, viz. 4 feet 8½ inches. Although the land taken is wide enough for a double way, being about 17 yards, there is at present only one pair of rails laid down from end to end. It is one of the rare instances of a railway being constructed entirely without river, road, or other bridges, which is owing to its peculiar locality; but there are five level road-crossings, and three of these are highways, which are furnished with folding gates, each 9 feet long, shutting both across the railway and roads, according as they are required.

The station at Aylesbury is conveniently laid out: a triple way, connected, at a convenient distance from the offices, with the main line, runs into a railway-dock 33 feet wide at its entrance, and 12 feet at its connexion with the [illegible] station, the [illegible] space of which is 4 feet 10 [illegible] the height of the quay, which has [illegible] batter of 2¾ inches, is 3 feet 4 inches; the quay on either side is about 10 feet in width. There is a carriage-dock 10 feet 8 inches in length and 8 feet 10 inches wide, furnished at its entrance with a proper turn-table, and abutting on the yard, conveniently situate for the arrival of common-road vehicles: the arrival door for passengers is at the booking-office, on the left side of the railway as you approach Aylesbury; the departure-gate is on the right side: for the whole length of the station there is a siding for carriages when not in use.

The booking-office and general waiting-room are in one; there is, however, a separate room for ladies. This is, upon the whole, one of the best-arranged stations for a short line of railway that we have any where met with.

On the Ballochney,

There is a self-acting plane of 1200 yards in length on that portion of the line next the Monkland Railway; the lower part being a single way, the middle part double, and the upper part formed with three rails. The ascending train consists usually of four loaded wagons, and the descending train of six or seven empty wagons; the time occupied in the ascent is 3·50 minutes; the rope used is about 4½ inches circumference; the sheaves are of 14 inches diameter, and are placed at intervals of 21 feet.

With regard to the Birmingham and Gloucester, Mr. Whishaw says,

The Lickey Incline of 1 in 37 extends for 2 miles 3·35 chains, and is, we understand, to be entirely worked by locomotive engines.

If this is satisfactorily effected, it will throw a new and useful light on the laying out of railways, and will save a vast original outlay in future works. We have long considered that the present system of making the sixteen feet gradient the *maximum*, is far from desirable. The advantages in working a railway thus graduated are not equivalent to the immense original outlay necessarily incurred by tunnels and overwhelming earthworks.

BRIDGES.—The whole number of bridges on this line is one hundred and sixty-two, besides one hundred and twenty-seven culverts. They are built of brick, of stone, of stone and iron, and some of wood. The span of arches over the railway is 23 feet; and the arches under the railway vary in span from 16 feet to 18 feet. The occupation-arches under the railway are each of 12 feet span.

There is a particular description of lattice-work wooden bridge used on this railway, which, we understand, was introduced from America by Mr. Hughes, the resident engineer; one of these we observed over a cutting near Bredon, which is about 117 feet in span, 17½ feet wide in the clear, about the same height, and 200 feet in extreme length.

The roadway planking is supported by transverse joists about 6 feet below the top rail of framing. These joists are placed about 3 feet from centre to centre, and have a bearing on each side on the middle rail, or band, which runs from one abutment to the other. Besides this band, there are two superior and two inferior bands, running the whole length of the lattice-work. Each end of the framing has a bearing on cross sleepers bedded in the solid ground in proportion to the span, and is let into a pedestal at each end. Beneath the level of the roadway, the lattice-work framing on each side is connected together with cross ties and braces, both of wood.

In order to give this bridge a horizontal appearance, the longitudinal timbers should have a slight camber. One of these structures, on our view of this railway, appeared to have sunk considerably in the middle.

The largest bridge is that which carries the railway over the river Avon, near Eckington. It consists of three cast-iron segmental arches, each of 73 feet span, and supported upon two lines of iron columns resting on iron caissons filled with masonry. The ribs and other castings of which this bridge is composed are not so sightly as they might have been; and the iron railing is of too studied a design for such a work. The whole length of this bridge is about 270 feet, and the clear width 23 feet. The total cost is stated to have been 10,000*l*.

It is a peculiar feature of this line, that although the rails are not laid throughout on longitudinal sleepers, there is an entire absence of stone blocks. This plan is gaining ground every day; and on some lines we have known sleepers substituted to a great extent for stone blocks, which had been originally introduced at great cost.

Of the travelling on the Brandling Junction our author seems to be by no means an admirer, for he says,

In consequence of opening this portion of the line at too early a period, the travelling over it was of the most extraordinary description we have experienced on any railway in the kingdom; for, besides the snail's pace at which the train proceeded, the motion of the carriages was precisely similar to that of a boat in a somewhat troubled sea.

It is an error, which most railway Companies have fallen into, to open their lines, or portions, before the embankments have sufficiently subsided to allow, if not of a safe, at any rate of an easy passage for the heavy trains made to pass over them. Some of the consequences of such hasty proceedings are to entail a large additional outlay on the proprietors, to bring discredit on the particular railway, and to give the now happily few enemies to the railway-system just cause for complaint.

A foot board on the carriages of the same line is more favourably noticed. The number of wagons seems large enough.

The second-class bodies, which are 14 feet 7 inches long, and 6 feet 2 inches wide, have also three compartments each, calculated to hold ten passengers. A footboard of wood, lined with plate-iron, runs along the whole length of the carriage on each side, and is of great convenience to the guards, who may thus safely walk along the side of the whole train when in motion.

There are nine goods-trucks, mounted each on Hawke's wheels.

There are upwards of 400 wagons at work on this line, built chiefly by Mr. Burnup, of Newcastle; but we were informed that the required number would be about 1500. The net weight of each wagon is about 44 cwt., and of size sufficient for 53 cwt. of coal. The wheels are of cast iron, 3 feet in diameter, and were generally furnished by Messrs. Hawkes and Co., of Gateshead. The cost of keeping a wagon in repair is estimated in this county at about 4*l.* per annum. The wagons are coated with tar—a practice which it would be very advisable for other railway companies to adopt.

With these few notes we must for the present leave Mr. Whishaw's work, observing that it contains a store of matter, from which we hope in our subsequent notices to extract, again impressing upon our readers the value of the present as a work of reference.

Gandy and Baud's Windsor Castle. Part II. London: Williams, 1841.

When Messrs. Gandy and Baud devoted themselves to the illustration of this national monument, they seem to have done so with a full determination to produce a work worthy the subject—a task which in this and the preceding number they have successfully carried out. The first of these fine plates presents us with a North West View of the Norman Gateway Towers and Queen Elizabeth's Building, a portion of the edifice in which two very dissimilar styles are placed in juxtaposition. This plate will we have no doubt be as great a favourite with the public as with the profession, for it unites great picturesqueness of effect with accuracy of delineation. Another work of the same class is the plate representing George the Fourth's Gateway and the York and Lancaster Towers, showing in the distance the Devil's Tower and the Great Round Tower. The elevation of Henry VII.'s and Queen Elizabeth's Gallery shows a range of building constructed under the several reigns of Henry 7th, Queen Elizabeth, Charles 2nd, Queen Anne, George 3rd and 4th, and William 4th, and made into one harmonious pile under the direction of Sir Jeffry Wyatville. Other plates in the work present a number of the details of the building, of great value to the student.

The promise held out by the publisher and conductors has been satisfactorily realized, so that we can have no hesitation in performing our duty of recommending most strongly this work to the patronage of the connoisseur, of the architect, of the student, and the public.

Excursions Daguerriennes. Part V. Paris.

We recommend this work to our readers. It comes out in numbers containing well executed engravings of scenes and buildings sketched by the Daguerréotype. In this publication the admirable capabilities of photography for architectural delineation is fully shown, and we have no doubt will prove extremely interesting. In this number are the Maison Carrée at Nismes, the Trajan column at Rome, the Church of Basil the Great at Moscow, and a view of the Mola at Naples.

A New Supplement to Euclid's Elements of Geometry. By the Author of a New Introduction to the Mathematics. London: Whittaker, 1840.

This is an ingenious work, by a well known author, propounding some new views, which will doubtless prove interesting to our mathematical readers.

Quarterly Railroad Journal, for January. Simpkin, Marshall & Co.

If no more railway bills pass, railway publications seem by no means afflicted with a similar sterility, for here we have before us a new contemporary. The *Quarterly Journal* contains several interesting papers on railway economy, emanating from one long experienced on the subject. Being devoted to the advocacy of the engineers against directors, it will doubtless be acceptable to many of our readers. We shall perhaps have occasion next month to advert to some of the views put forward, which will afford the best proof of the interest we take in this publication.

The Law and Practice of Letters Patent for Inventions: Statutes, Practical Forms, and Digest of Reported Cases. By Thomas Webster, Esq., of Lincoln's Inn, Special Pleader. London: Crofts and Blenkarn, 1841.

It is probably unfortunate for the author of this work that the nature of the subject upon which he treats is such as to prevent us from making extracts from it, such as would enable our readers to form an independent judgment upon it. They will perhaps however feel equal confidence when, without such testimonials, we refer them to Mr. Webster's book, as one which for clearness and completeness is much to be admired, whether as regards its application to this particular subject, or considered merely by a legal standard. The arrangement of the work is excellent, and the manner in which the information is epitomized not less so. Any one by a careful perusal of it, will be easily enabled to understand the rationale of a subject so important.

The Doctrine of Proportion clearly Developed, &c., or the Fifth Book of Euclid Simplified. By Oliver Byrne, &c. London: Williams, 1841.

"Censure on the works of others," says the author before us, "should be avoided as much as possible, because it shows the want of knowledge; those who know least, censure most: to correct a copy is easier than to produce an original; for men acquire criticism before ability, and it is mostly from those who possess no judgment that the most sweeping judgment comes." This is immediately followed by a general attack on Newton, Legendre, Simpson, Brewster, Professors Young and Leslie, Keith, Bonnycastle, Austin, Da Cunha, &c.

This is a very pretty brick from the work of Mr. Byrne, his book abounding with similar looseness and inconsistency. We will not quarrel with Mr. Byrne's definition of criticism, for he evidently does not know what it is, but at once dismiss him by observing that his book leaves the subject just where he found it, and that had he simply announced it as an edition of the Fifth Book with symbolical, arithmetical and algebraical expositions, we should have had less occasion for complaint at the nonfulfilment of his high sounding promises.

LITERARY NOTICES.

The fourth volume of the *Papers of the Corps of Royal Engineers* has been sent to us, but we have only time now to say that it appears to excel the character of its predecessors.

Another work published by Mr. Weale, *The Reports, Specifications and Estimates of Public Works in the United States of America,* must also be passed over for the present. It is a work of that magnitude and value that we should be doing injustice to it to attempt any cursory delineation of its contents.

ON THE COMBUSTION OF COAL.

Sir—With your permission I beg to offer some remarks on the review of my treatise "on the Combustion of Coal," inserted in the last number of your useful Miscellany. Commenting on a passage in my work, the reviewer observes, "is this a proof of the great value of coal as a heat-giving body? certainly not: it is the contrary; rather an evidence of the great quantity of heat expended in evolving the gas, which is no advantage, but very much the reverse." In my treatise I have strongly insisted on this point, as put by the reviewer, namely, the heat expended in evolving the gas, comparing it with the heat expended in converting ice into water, and water into steam. I fear however, the reviewer has overlooked the object I had in view, which was, not to shew, "the great value of coal gas as a heat-giving body," but as proof of the enormous quantity of it which coal contains, and the importance of turning it to account in the furnace.

The reviewer charges me with having made use of an improper term, and observes, that the expressions "bitumen, and bituminous portion" ought to be rejected, and, "gases and gaseous or volatile portion" substituted in their place. That the terms "bitumen," and "bituminous portion" are strictly speaking, not correct, is true, because, as Dr. Ure observes, "Coal contains no ready-formed bitumen, but merely its elements, carbon, hydrogen and oxygen." I beg however to observe, that the terms, "gases," and "gaseous portion" would not explain my meaning, for this reason, that the portion of the coal, which in common parlance is called "bituminous," is in a solid or fixed state while in the coal, and to which state I was then referring; though, subsequently, it is volatilizable and assumes the form of gas. I know, indeed, no other term by which these bituminous constituents, *while in the fixed state in coal*, and before they are volatilized, can be designated.

The reviewer observes, "these quotations [taken from page 26,] suffice to shew that the gases which result from the application of heat to coal, are considered by the author to be produced by *simple distillation* of the bitumen contained in the coal, which suffers thereby no alteration in its chemical composition; whereas, the truth is, that they result from the chemical decomposition of the bitumen, &c."

I beg to explain my meaning, by saying that I intended to convey the idea that the application of heat to coal expels the bituminous and volatizable part by a distillatory process, and in corroboration of this opinion I find Dr. Ure says, "the first operation which coal undergoes on being heated in a common furnace, is, *distillation*."

I accompany the present with Dr. Ure's letter, from which I have made the above quotations.

And am, your obedient servant,

C. W. WILLIAMS.

Remarks by Andrew Ure, M.D., F.R.S., on Mr. Williams's Treatise on the Combustion of Coal.

To C. W. WILLIAMS, Esq.

HAVING now carefully perused your treatise "On the Combustion of Coals and the Prevention of Smoke, Chemically and Practically considered," I cannot help congratulating you on the profound manner in which you have studied the phenomena of a furnace—phenomena which, like those of the freezing and boiling of water, had been for ages exhibited to the eyes of the philosopher and the engineer, without receiving from the one a scientific analysis, or leading the other to any radical improvement. You have fully demonstrated the defectiveness and fallacy of the ideas generally entertained concerning the operation of fuel in furnaces, and the errors, consequently, committed in their construction. Nothing places in a clearer light the heedlessness of mankind to the most instructive lessons than their neglecting to perceive the difficulty of duly intermingling air with inflammable vapours, for the purpose of their combustion, as exhibited in the every day occurrence of the flame of a tallow candle, or common oil lamp; for, though this flame be in contact, externally, with a current of air created by itself, yet a large portion of the tallow and oil passes off unconsumed, with a great loss of the light and heat which they are capable of producing. Your quotations and remarks upon this subject must convince every unprejudiced mind of the justness of your views as to the imperfect combustion of the inflammable gases given out by coals on the furnace grate.

By experiments with Dr. Wollaston's Differential Barometer, made in several factories, where both high and low pressure steam was employed, I found, that the aërial products of combustion from the boiler furnaces flew off with a velocity of fully 36 feet per second;* a rate so rapid as to preclude the possibility of the hydrogenated gases from the ignited coals becoming so duly blended with the atmospheric oxygen as to be burned. It is well known, that elastic fluids of different densities, such as air and carburetted hydrogen, intermingle *very slowly*; but, when the air becomes conbonated, as it does in passing through the grate, and, consequently, heavier, it will not incorporate at all with the lighter combustible gases above it, in the short interval of the aërial transit through the furnace and flues. Thus there can be no more combustion amidst these gases and vapours than in the axis of a tallow candle flame.

Your atomic representations are quite correct, and will please all those who delight in tracing the workings of nature into her formerly mysterious and inaccessible sanctuary.

You will remember that when, about ten months ago, you laid before me the first draught of the specification of your patent furnace, with what delight I hailed your invention as the harbinger of a brighter day for steam navigation, where economy of fuel has become the *sine quâ non* in regard to long voyages. I rejoice that, with the ample means placed at your command, you have since prosecuted the subject, through all its ambiguities, to a clear and conclusive demonstration of the efficacy of your plan for calling forth from pit-coal all its dormant fire, and diffusing it most efficaciously over the surfaces of boilers and along the flues. I am more particularly pleased with your analysis of the combustion of the gases and vapours given out by hydrogenous coal, commonly, though incorrectly, called bituminous, for it contains no ready-formed bitumen, but merely its elements, carbon, hydrogen, and oxygen.

Having been much engaged, during the two preceding years, in experimental researches upon the calorific powers of different species of fuel, † I became aware that the hydrogenous constituents of coal underwent a most imperfect combustion, and found I had been misled for some time to the false conclusion, that the caking Newcastle coals afforded less heat than the non-hydrogenous anthracite of Wales. When I improved my method of burning the gaseous products first disengaged from coals, I obtained a greater quantity of heat from the so-called bituminous species; a result quite in accordance with long established chemical data. The immortal Lavoisier and Laplace ascertained, that one pound of hydrogen, when burned in their celebrated calorimeter, melted 295·6 lb. of ice, while one pound of charcoal melted only 95·6 lb., quantities very nearly in the ratio of 3 to 1; Despretz gives the ratio of 315 to 104; thus proving beyond a doubt, that hydrogen can disengage, in its combustion, three times more heat than the same weight of charcoal. It deserves to be remarked, that this ratio is exactly the inverse of that in which hydrogen and carbon unite with oxygen; for 1 part of hydrogen, by weight, combines with 8 of oxygen to form water; and 3 parts of carbon combine with 8 of oxygen to form carbonic acid gas, which is the product of the complete combustion of charcoal. From these and similar researches, chemists have been led to conclude, that the heat afforded by different bodies in the act of their combustion is proportional to the quantity of oxygen which they consume; a conclusion which accords, also, with the principle, that the intensity of heat is proportional to the intensity of chemical action, as measured by the proportion of oxygen which enters into combination.

For the first accurate analysis of pit-coals, we are indebted to Mr. Thomas Richardson of Newcastle,* who published, a few years ago, in the eleventh volume of Erdmann's Journal für Chemie, the results of an excellent series of researches on coals, made in Professor Liebig's laboratory. He used the fused chromate of lead to oxygenate the carbon and hydrogen of the coals, with Liebig's new apparatus; and his results deserve entire confidence. In the earlier analyses of coals, made by Dr. Thomson, myself, and others, the peroxide of copper, which was employed to oxygenate the combustible matter, always left some of the carbon unconsumed, and thus occasioned unavoidable errors.

1. Rich caking coal, from Garesfield, near Newcastle, of sp. grav. 1·280, was found to contain as follows:

Carbon	87·952
Hydrogen	5·239
Azote and oxygen	5·416
Ashes	1·393
	100·

2. Caking coal, of excellent quality, from South Hetton, in the county of Durham, of sp. grav. 1·274, afforded,

Carbon	83·274
Hydrogen	5·171
Azote and oxygen	9·036
Ashes	2·519
	100·

3. The parrot coal of Edinburgh afforded,

Carbon	67·597
Hydrogen	5·405
Azote and oxygen	12,432
Ashes	14·566
	100·

100 parts of these several kinds of coal take for perfect combustion (subtracting the oxygen contained in the coal) as follows:

1st. 266·7	parts of oxygen: giving out heat as the number	122·56
2nd. 250·2	,, ,, ,,	114·98
3rd. 217·6	,, ,, ,,	100·00

The quantity of heat is here presumed to be proportional to the quantity of oxygen consumed. M. Regnault published, in Erdmann's Journal, vol. xiii., p. 69, the following statement of his analysis of coals, which is regarded by Professor Löwig as very correct:*

Newcastle coal, of sp. grav. 1·280, affording a much inflated coke, (quite akin to the Garesfield coal, if not the same,) was found to consist of carbon, 87·95; hydrogen, 5·24; azote and oxygen, 5·41.

A Lancashire coal, of sp. grav. 1·317, which afforded an inflated coke, was found composed of carbon, 83·75; hydrogen, 5·66; azote and oxygen, 8·04. The quantity of azote is not given separately by either Mr. Richardson or M. Regnault; but it is known to be inconsiderable. The deficit to 100 in his analyses represents the amount of ashes per cent. Mr. R. says: "With the present means of analysis at our disposal, it is impossible to determine the true amount," (of azote,) "but the coal cannot contain more than two per cent." In the Edinburgh coal he found, by an experiment made on purpose to determine this point, 0·38 per cent. of azote. This uncertainty introduces a proportional ambiguity into the calculation of the quantity of heat evolved, from the quantity of atmospherical oxygen consumed. The less the proportion of azote, in the above analysis, the greater will be that of the oxygen directly combined with the coals, and the less atmospherical oxygen, of course, will be consumed, which is the only source of the heat disengaged.

Since it is the proportion of hydrogen in coal that determines the proportion of volatile products, a tolerable approximation upon this point is afforded by the proportional loss of weight which different coals suffer from ignition in retorts or covered crucibles. I found that 100 parts of the Felling-main coal used by some of the London Gas Companies, when strongly ignited in a covered crucible, well-luted, lost 37·5 per cent., leaving 62·5 of a porous coke. The Llangennock coals from Caermarthenshire, of sp. grav. 1·337, lose by ignition only 15·5, and leave 84·5 of a rather dense coke, which contains 3 of ashes. In furnaces of the common construction about London this coal affords much heat with little smoke, and is, therefore, greatly in request, and fetches a high price. 100 parts of the Tanfield Moor coal, of sp. grav. 1·269,

† An account of these experiments was laid before the meeting of the British Association, at Birmingham, and printed in the *Athenæum* of September 14, 1839.

* Experimental Inquiry into the Modes of Warming and Ventilating Apartments, in reference to the Health of their Inmates. By Andrew Ure, M.D., F.R.S. Read before the Royal Society, 16th June, 1836.

* An account of these experiments has been since presented, by Mr. Richardson, to the Natural History Society of Newcastle-upon-Tyne, and is printed in their Transactions, vol. ii., p. 401, and in the London and Edinburgh Philos. Magazine, vol. xiii., p. 121, for August, 1838.

† Chemie der Organischen Verbindungen, vol. ii., p. 88.

preferred by blacksmiths for their forge on account of its calorific strength and freedom from sulphur, give off in ignition 32·5 parts, and leave 67·5 of a bulky, compact coke.

Every coal which contains much hydrogen, and, therefore, loses much weight by ignition in retorts, necessarily produces much smoke, with a great waste of heat in our common steam boiler furnaces, for reasons which you have so well developed in your treatise. "When a carburetted hydrogen," says Liebig, "is kindled, and just as much oxygen admitted to it as will consume its hydrogen, the carbon does not burn at all, but is deposited (or separated) in the form of soot; if the quantity of oxygen is not sufficient to burn even all the hydrogen, carburets of hydrogen are produced poorer in hydrogen than the original carburetted hydrogen."* The above gas and smithy coals which, from their richness in hydrogen, are capable of affording the greatest proportion of heat by thorough combustion, afford often a much smaller quantity than the Llangennock, because the carburetted hydrogen which they so abundantly evolve is not supplied with a *due* quantity of oxygen, and hence much of their carbon goes off in smoke, and their sub-carburetted hydrogen gas in an invisible form. These results are quite accordant with my experiments on these coals with my calorimeter. At first, from certain defects in the apparatus, whereby the coals were imperfectly burned and a good deal of smoke was disengaged, I found that the best coals imported into London, such as Lambton's Wallsend, Hetton Do. and Pole's Main, afforded a smaller proportion of heat than the Llangennock, or even anthracite; but, when I diminished these defects, I obtained much more heat from the Tanfield Moor coal than from the Llangennock, and more from this than from the anthracite. In fact, a coal which, like the Newcastle caking coal, contains 5·239 of hydrogen, is capable of giving out in complete combustion as much heat as if it contained an extra $10\frac{1}{2}$ per cent. of carbon; but, instead of this additional heat, it affords in common furnaces much less heat than the Llangennock, though this is much poorer in the most calorific constituent, viz., the hydrogen.

It is a remarkable fact, that an inflammable constituent of pit-coal, which is always present, and often invisibly combined with it to the amount of 5 per cent. or more, has never been noticed in any of the ultimate analyses hitherto published. I have examined a great variety of coals from different parts of the world, and I have seldom found less than 2 per cent. of sulphur in them. Now, this is a circumstance of great consequence to many manufacturers, and most essentially to iron-masters. Some of my results upon this subject were published in the number of the Athenæum above quoted. Sulphur in its calorific power ranks low, being, according to Dr. Dalton, one-half of carbon. If we assume its consumption of oxygen in combustion as the measure of its heating power, it will stand to carbon in the relation of 3 to 8; for 3 parts of carbon consume 8 of oxygen to form carbonic acid, while 8 of sulphur consume 8 of oxygen when they are burned into sulphurous acid. The blacksmith knows well what havoc a sulphurous coal makes among his iron in the forge, rendering it entirely *rotten*. The same operation takes place upon the rivets and plates of steam-boilers, when the sulphur of the coals is merely volatilized, without being mingled with sufficient air to burn it.

The first operation which coals undergo on being heaved into a common furnace, is distillation, attended with a great absorption of heat, and may be compared to the distillation of sulphur in the process of refining it, for which purpose much external heat is requited. But, if the fumes of sulphur or the coals be, after accension, intermingled with the due quantity of atmospherical oxygen, they will, on the contrary, generate internally from the beginning their respective calorific effects.

At the outset of my chemical career I suffered in a painful and dangerous way from the refrigeration produced by throwing some pit-coal into a hot furnace. I was extracting oxygen, for common class experiments, from nitre ignited in a large iron bottle, when, having replenished the fire with coal, the gas became condensed in the bottle so much as to occasion a regurgitation of water into it from the gasometer basin, which water, being instantly converted into high-pressure steam, drove out a quantity of red-hot nitre upon my shoulder and arm, so as to burn not only my clothes, but a very considerable portion of my skin. In an experimental furnace, so treated, the heat is greatly damped as long as the hydrogenated vapours and gases are being generated; and it becomes again effective only when the coals have become nearly charred. Were there a contrivance like your patent invention introduced into the furnace for diffusing atmospherical oxygen through the said vapours and gases, no vexatious refrigeration could ensue from feeding the fire prudently, with common pit-coal; and the external orifice through which this smoke-burning air was admitted, might be closed whenever the fire became clear.

In the case of great steam-boiler furnaces, for which your patent is especially intended, since these are fed at short intervals, your plan of distributing atmospheric air, in a regulated quantity, by numerous jets, through the body of the gasiform matter, is peculiarly happy, and enable you to extract the whole heat which the combustible is capable of affording. The method also which you have contrived for distributing the air under the surface of the grate will ensure due combustion of the coked coals lying there, without admitting a refrigerating blast to the fire. And, finally, your mode of supplying atmospherical oxygen will prevent the possibility of the carbon of the coals escaping in the state of carbonic oxide gas, whereby, at present, much heat is lost in our great furnaces.

ANDREW URE.

LECOUNT'S HISTORY OF THE LONDON AND BIRMINGHAM RAILWAY.

SIR—In your last number you have unintentionally done me an injury, which I have no doubt you will redress by admitting this letter. I allude to your stating that my history of the London and Birmingham Railway is a reprint from Mr. Roscoe's. I beg to say this is not the case beyond the 32nd page; the remainder of my work is what it proposes to be, a history of the railway in question, which Mr. Roscoe's is not beyond page 32—after that point I had nothing whatever to do with it, principally on the account that it was professing what was not to be performed. My name being connected with it is a perfect hoax upon the public; I never saw a proof sheet after page 32; and I may add that what I furnished for that work, although done under a written agreement, has never got me a sight of sixpence of the publisher's money. Beyond the point named it may be just as correctly called my history of the Cock Lane ghost, as my history of the Birmingham railway; I had nothing whatever to do with it except as above explained

Your obedient servant,
P. LECOUNT.

Wellington Road, Birmingham,
January 7, 1841.

[We should regret extremely that any unintentional error of ours should be the means of injuring Lieut. Lecount, for whose public services we entertain great respect, perhaps his letter will be deemed a sufficient explanation. —ED. C. E. & A. JOURNAL.]

Fig. 1.

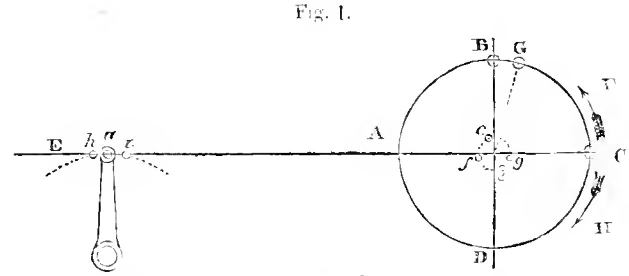

Fig 2.

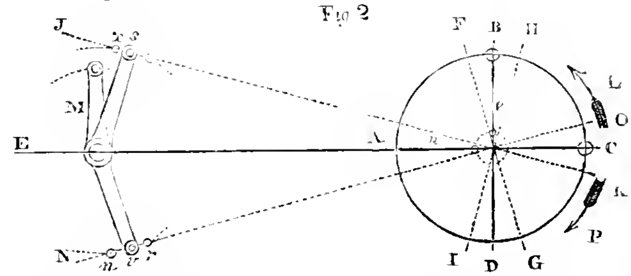

[We very much regret that, through the inadvertence of our wood engraver, several letters of reference were omitted in Mr. Pearce's diagrams given in last month's Journal; we have therefore thought it our duty to re-insert them, together with the following communications.]

SIR—I beg to call your attention to my communication on Eccentrics for working the slide valves of Locomotive Engines, which you were pleased to insert in the last number of your widely circulated Journal.

On reading the explanation of the engravings, I find that the greater part of the letters of reference are not inserted in the figures; this omission, I think you will perceive, renders the most important point of the subject unintelligible, and I have, therefore, taken the liberty to apprise you of the same, hoping that you will be induced to correct the deficiency by the insertion of the figures complete in your next number. I also beg to point out the two following typographical omissions. In the 5th line of the 6th paragraph, instead of "Suppose it to be, &c." it ought to have been "Suppose *the crank* to be, &c.," and in the 11th line of the last paragraph, instead of "caused to be, &c." it ought to have been "caused *not* to be, &c."

I remain, Sir,
Your obliged servant,
JOHN C. PEARCE.

Leeds,
Jan. 13*th*, 1841.

Sir—I have subscribed to your periodical from its commencement, and received from it much pleasure and useful information. I have been still more gratified of late with the increase of space devoted to my favourite study, mechanics, and it is to a paper of this nature in your January number, that I wish at present to direct your attention. A correspondent of the name of John Charles Pearce describes, at considerable length, a contrivance for reversing a steam-engine with one eccentric as an invention of his own, although it has long been quite common in this country. I may mention, as an example, a high-pressure engine of about 20 horse power, built for some experiments with a canal boat on the Forth and Clyde Canal, and afterwards altered as a pumping-engine for a dry dock at Grangemouth, in which the identical contrivance was applied successfully.

I am,
Your constant reader,
An Apprentice.

Glasgow,
11th Jan. 1841.

Sir—If I am trespassing too much on your columns by thus a second time requesting the favour of a place therein, I beg you will suppress, curtail, or defer, as you think best, the following remarks which I am induced to send you after the perusal of a communication from Mr. John Charles Pearce, inserted in your number for the present month.

Mr. J. C. Pearce is correct in his observation as to the possibility of working Locomotive Engines by two fixed eccentrics, but he overlooks an objection to this system which, with your permission, I will take the liberty to point out: previous however to entering upon the objection, it will be proper to explain a few conditions, which are inseparable from this system of two fixed eccentrics and in one of which, originates the above mentioned objection.

No. 1. The eccentric must precede the crank in its action, when the engine is going forward, otherwise no *lead* can be given without a complication of levers: a slight objection was made to this, inasmuch that for going forward, the eccentric rod must work the upper pin of the double lever of the valve motion, and must be held in gear, so that should any thing get wrong in the hand motion, the eccentric rod would fall out of gear, and would thus reverse the engine.

No. 2. The crank being placed in a horizontal position, so that the piston may be at one end of the cylinder, the eccentric must be placed exactly perpendicular to Mr. J. C. Pearce's line C E. which is a straight line drawn through the centre of the crank shaft, and the lever spindle of the valve motion.

No. 3. The *amount* of *lead* depends upon the length of the eccentric rod. The shorter this rod is the greater will be the *lead*.

No. 4. The *lead* being determined by the length of this rod must remain invariable unless you move the eccentric on the axle, in which case you increase the *amount* of the *lead* one way, *but you diminish it for the reverse motion.*

This last circumstance has been deemed objectionable, because with varying loads and speed, it is desirable to have the power of augmenting or diminishing the *amount* of the *lead*.

Several engines are at work on the Paris and St. Germain railway fitted each with two fixed eccentrics, upon the principle laid down by Mr. J. C. Pearce, and for which a patent was obtained in Paris, I believe in 1838. They work well, but in consequence of the above mentioned inconveniences are being fitted with four eccentrics.

I have had several opportunities of comparing the duty done by these engines with that of others having four eccentrics, and at work on the same line, and have found very little difference in their results. I have reason to believe that the determination to alter them, originated more than from any other cause, in the desire of the Company to assimilate all their engines, by adopting one uniform system of eccentric motion; it is proper here to observe that the eccentric rods of these engines were originally made too long, and did not give sufficient *lead* to the valves, that in consequence thereof, the eccentrics were advanced a little on the shaft, so as to give the required *lead* for going forward, and the engines were *thus rendered slow the back way.*

The same Company fitted a pair of fixed eccentrics to another engine, paying proper attention to the length of the eccentric rods in order to obtain the required *lead* both ways; the eccentric rods were in this instance so short, as to work with a disagreeable motion, because the suspension pin of the hand lever motion, which in consequence of the shortness of the eccentric rods was attached to them, comparatively nearer than usual to the eccentric, occasioned an up and down motion of the fork upon the pin of the lever of the valve motion, which made it requisite to make the parallel clutch of the fork much deeper than usual, to prevent it from flying out of gear; this might, it is true, have been easily remedied, but the Company not being willing to make any further outlay in experiments, and desirous to have their engine, replaced the whole affair by four eccentrics.

The most serious objection made to the two fixed eccentrics, in my opinion, rests on the impossibility of varying the *lead of the valves both ways.*

The original plan adopted of two moveable eccentrics is a very good one, because if any thing gets out of order with the motion, you can always work home by hand. The main objections are, their expence, and the difficulty of getting them sufficiently strong.

The four eccentrics act perfectly well, but render the valve motion so very crowded, as to be frequently inconvenient.

A very ingenious method has been proposed and executed by Messrs. Hawthorn, brothers, of Newcastle-upon-Tyne, for replacing the eccentrics altogether, by a motion taken from the body of the connecting rods: the *lead* has been very cleverly determined by these gentlemen: the same objection however exist as to the difficulty of varying the *lead*, which could only be removed by complicating the motion. I have seen an engine of this description at work and giving satisfaction.

I remain, Sir, your very humble servant,
H. E.

London, January 16, 1841.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Jan. 11.—J. B. Papworth, Esq., in the Chair.

A paper was read by Mr. E. I'Anson, Jun., Fellow, comparing the Campanili of the lower ages in Italy, with those of the Norman period in England. The matter of Mr. I'Anson's discourse went to illustrate that highly interesting subject, the spread of the Romanesque style of architecture, and the modifications it underwent in its progress.

Jan. 25.—H. E. Kendall, Esq., in the Chair.

A paper was read on the Construction of the Reservoirs from which Venice is supplied with fresh water, by C. Parker, Fellow. This city being dependant on the clouds for a supply of this most necessary element, means are provided for collecting the rain water in immense tanks, which it enters by filtration through beds of sand, the means by which natural reservoirs are fitted, and their contents purified, being in fact imitated by art. The mode of constructing and puddling these tanks was described in detail, and illustrated by plans and sections.

An Artesian well lately constructed at the Surrey County Lunatic Asylum, was described by Mr. S. Lapedge, Associate, and a section exhibited of the strata through which the borer has passed, to the depth of 347 feet. The water rises from a bed of dark sand to within 30 feet of the surface, and a well 190 feet deep forms a reservoir, which constantly affords a supply sufficient for the purposes of the establishment.

A drawing was presented and a discussion read of a timber bridge erected at Hulne Park, by Mr. Barnfather, architect. It is an arch of 100 feet span and 5 feet rise, constructed of balks of timber raised to a curve by means of iron wedges, and remarkable for the simplicity and economy of construction. This principle was introducted from America about 25 years ago.

The Secretary for foreign correspondence, Mr. Donaldson, read a communication from Baron Gasparin, President of the Comité Historique des Arts et Monumens, at Paris, accompanying a donation of the bulletins (or reports) of the committee.

SOCIETY OF ARTS FOR SCOTLAND.

Dec. 14, 1840.—Dr. Fyfe, President, in the Chair.

Mr. Galbraith read a paper *on Trigonometrical Levelling, and on the effects of a supposed local attraction at the Calton Hill, Edinburgh.* In the first part of the paper he detailed a number of observations which he had made for the purpose of determining the amount of atmospherical refraction, and described a formula for its computation considerably simpler than that in use. In the second part of his paper he detailed a series of observations for the purpose of determining the latitude of the observatory of Edinburgh, to which he had been led by a known discrepancy between the latitude determined by Professor Henderson, from observations made by the mural circle, and the latitude found from the observations made on Kelly Law, in Fife, by help of the Ordnance zenith sector. It having occurred to him that the rising of the country to the southward of the Calton Hill, and the slope northward to the Firth of Forth, may cause a local disturbance of the plumb line, he resolved on deducing the latitude of the Observatory from observations made on Inchkeith, in the middle of the Firth, where the local attractions may be expected to be balanced. The determination of the latitude of Inchkeith Light-house agreed within half a second with that found by the Ordnance surveyors, but differed by *seven seconds* from that deduced by transference from the Observatory. On this account the author conceived that the probability of the existence of a local attraction at the Calton Hill was strengthened. The paper was ordered to be printed.

Mr. Alexander exhibited *a working model of the Electric Telegraph*, having premised that the model was intended merely to illustrate elementary principles. This instrument contained a separate wire for each distinct signal: the exhibition of it gave rise to an interesting conversation, in which a number of the members took part. Mr. Ponton adverted to the modification which he had exhibited two years ago to the society, in which a sufficient number of signals were obtained by the use of three wires only; he also mentioned that during the exhibition in the Assembly rooms, he had openly talked of a method of reducing the number of wires to two, by introducing the element *time*, a simplification which has since been wrought out and patented by Professor Wheatstone.

Mr. James Robertson, late in the service of the Shah of Persia, read a paper *on the method of manufacturing Bricks in Persia*; in which a lucid and very interesting description was given of those peculiarities in the construction of the brick-kilns which are consequent on the scarcity of fuel, and the peculiarity of what fuel can be obtained. Mr. Robertson was requested to allow his paper to appear in the transactions.

Jan. 11. 1841.—The President in the Chair.

Mr. Gavin Kay exhibited *a model of a boat on skates*, which he proposed as an apparatus for saving the lives of persons who have fallen through the ice. The exhibition of this model led to an animated conversation concerning the general subject, in the course of which Dr. Hunter, Mr. Sang, and Mr. Glover, expressed opinions decidedly hostile to any cumbrous apparatus; Mr. Sang and Mr. Glover particularly insisted on the propriety of having a few men drilled to manœuvring on the frequented lochs; and the society, after thanking Mr. Kay for his communication, requested Mr. Glover to draw up a paper embodying the opinions which seemed to have prevailed, and particularly the lucid views which he himself had given.

Mr. Rose read a description of *an instrument for indicating the amount of inclined disturbances during the shocks of an Earthquake*. In introducing the subject, Mr. Rose stated that since this communication had been billeted, the very same instrument had been exhibited to the Royal Society (Edinburgh), and that, in consequence, he had thought of withdrawing the notice. Having been dissuaded from this intention, he felt it necessary to offer some explanation. The explanation was to the effect that Mr. Mylne, having been requested, along with a committee of the British Association, to devise instruments for registering the disturbances caused by earthquakes, had consulted him, and having received a description and sketch, had employed Mr. Jamieson, assistant to Mr. Lees, to construct one. This instrument Mr. Mylne had exhibited along with others to the Royal Society, without taking any notice of Mr. Rose. The instrument contained a pendulum suspended by a ball-and-socket joint, the lower extremity of the pendulum carrying a piece of chalk, which might trace, upon a blackened spherical surface, a line to indicate the amount and direction of the inclination. Mr. Rose explained that some slight friction is needed, in order to prevent the free swinging of the pendulum, and he added that very little information could be expected from instruments of this class, since, in localities where the shocks are slight, the indicators may be deficient in delicacy, while, on the occasion of severe shocks, the instrument and observers may be involved in the common ruin. Sir John Robison pointed out a difficulty which might occur in interpreting the readings of the instrument, and suggested a hollow but very flat cup containing mercury; in the sides of the cup were to be drilled a multitude of small holes, which, in the event of any disturbance, might receive and retain part of the mercury. After some conversation among the members, thanks were voted to Mr. Rose.

Mr. Thomas Davidson exhibited a simple but important *improvement in the camera for taking portraits*. This improvement consisted in placing a stop between the lens and the image, so as to cut off the worst portions of the refracted light. He also described a method proposed for the purpose of taking views by reflection. His method was to employ a perfectly spherical reflector, having a stop placed around the centre of curvature; by this means all parts of the image are obtained of equal distinctness. Sir John Robison, Dr. Hunter, and Mr. Bryson made some remarks, and Mr. Sang pointed out that the curvature of the image in this arrangement would be a source of great inconvenience. These communications were remitted to a committee.

MEETINGS OF SOCIETIES IN FEBRUARY.

At Eight o'clock in the Evening.

Architectural Society, Tuesday	9	23		

STEAM NAVIGATION.

THE VOYAGE OF THE NEMESIS.

(From the Colombo Observer, Oct. 12.)

In this splendid vessel, commanded by Captain W. H. Hall, we have the pleasing task of welcoming to our shores the first iron steamer that ever rounded the Cape of Good Hope. She is the largest of her class built, being 168 feet long, 29 feet beam, and 650 tons burden. The engines are 120 horse power, by Messrs. Foster and Co., of Liverpool, and, of course, upon the best construction. Twenty days' coal can, on any emergency, be stowed in her. She carries two medium 32 pound pivot guns, one after the other forward, and 10 swivels, and is manned by 50 seamen. When launched she drew only 2½ feet water, and may still be lightened, if necessary, to 4½ feet. Being nearly flat-bottomed, and fitted with iron hawse holes for cables in the tern, she can be run on shore and easily got off again by anchors, which contrivances will enable her, in many cases, to land troops without the assistance of boats. Though thus round-bottomed, two wooden false keels, of six feet in depth, can be let down through her bottom, one after another, forward. These, together with a lee-board invented by Captain Hall on the voyage, prevent her, in a considerable degree, from going to leeward. The rudder has a corresponding construction, the true rudder going to the depth of the sternpost, and a false rudder being attached by a pivot to the former, so that it can be triced up or let down to the same depth as the false keels. The floats are easily unshipped, and under canvass, with the wind free, she can go 9 or 10 knots an hour. The vessel is divided by water-tight divisions into five compartments, so that though even both stem and stern were stove in, she would still float. Her accommodations and arrangements of small arms are splendid, and large coal-holes being placed, both between the officers' quarters and the sailors' berths and the engine-room, the heat of the fires is not at all felt. The Nemesis left Portsmouth with secret orders on the 28th of March, and reached Madeira in seven days, where she took in coals, then proceeded down the coast of Africa, steaming or sailing according to circumstances, but she experienced principally adverse winds and currents. At Prince's Island, a Portuguese settlement, she took in 70 tons of wood, which, with the remaining coals, lasted till she came into the latitude of St. Helena, when she proceeded under canvass, in order to make the best of her way to Table Bay thus facing the Southern Ocean at the very worst season of the year.

She arrived at Table Bay on the 1st of July. The Governor and suite having gone on board, she slipped from her anchorage and steamed round the bay, trying the different range of her guns. Having taken in about 200 tons of coals and water, she left Table Bay on the 11th of July, and whilst rounding the Cape, as was to be expected at that most unfavourable season, experienced several gales of wind. One of these, in particular, was most tremendous, but, to the agreeable surprise of those on board, the steamer proved to be an admirable sea-boat, rising over the immense waves with the greatest buoyancy, and shipping little or no water. She, however, received so much damage in these gales, that Captain Hall put into English river, Delagoa Bay, to repair and refit. This occupied three weeks, but was done most effectually by those on board, as she carries first-rate artificers and ample means at their disposal.

From Delagoa Bay the Nemesis proceeded to Mozambique, thence she continued her voyage towards India, calling at Johanna. She then went direct through the Maldive islands to Ceylon, sighted Colombo on Monday morning, the 7th, and reached Point de Galle the same afternoon.

The Nemesis will have to wait a few days at Point de Galle until the arrival of commissariat and other stores from Colombo, when it is supposed she will proceed to Singapore, and ultimately to China.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 28TH DECEMBER, TO 28TH JANUARY, 1841.

Six Months allowed for Enrolment.

John Buchannan, of Glasgow, Coach Builder, for "*improvements in wheel carriages for common roads or railways*."—Sealed December 28.

William Bridges Adams, of Porchester Terrace, Gent., for "*improvements in the construction of wheel carriages, and of appendages thereto*."—December 28.

John Wells, of Vale Place, Hammersmith, Gent., for "*certain improvements in the manufacture of coke*."—December 30.

William Henry Kempton, of the City Road, Gent., for "*improvements in cylinders to be used for printing calicoes and other fabrics*."—Dec. 30.

Henry Adcock, of Winstanley, Civil Engineer, for "*improvements in the means or apparatus for condensing, concentrating, and evaporating aeriform and other fluids*."—December 30.

William Heusman, of Woburn, Machinist, for "*improvements in ploughs*."—December 31.

Joseph Parkes, of Birmingham, Button Manufacturer, for "*improvements in the manufacture of covered buttons*."—December 31.

William Newton, of Chancery Lane, Civil Engineer, for "*improvements in the rigging of ships, and other navigable vessels*." Communicated by a foreigner.—December 31.

Francis Burdett Whitaker, of Royton, Lancaster, Cotton Spinner, for "*improvements in the machinery or apparatus for drawing cotton and other fibrous substances, which improvements are also applicable to warping and dressing yarns of the same*."—December 31.

Joseph Stubs, of Warrington, File Manufacturer, for "*improvements in the construction of screw wrenches and spanners, for screwing and unscrewing nuts and bolts*." Communicated by a foreigner.—December 31.

Thomas Robert Sewell, of Carrington, Nottingham, Lace Manufacturer, for "*improvements in obtaining carbonic acid from certain mineral substances*."—December 31.

William Henry Kempton, of Pentonville, Gent., for "*improvements in lamps*."—December 31.

John Grylls, of Portsea, for "*improvements in machinery used for raising and lowering weights*."—December 31.

Joseph Haley, of Manchester, Engineer, for "*an improved lifting jack, for raising or removing heavy bodies, which is also applicable to the packing or compressing of woods or other substances*."—December 31.

Louis Holbeck, of Hammersmith, Gent., for "*improvements in obtaining or producing oil*." Communicated by a foreigner.—December 31.

Henry Scott, of Brownlow Street, Bedford Row, Surgeon, for "*improvements in the manufacture of ink or writing fluids*."—December 31.

Charles Goughtly, of Gravel Lane, Southwark, Gent., for "*a new apparatus for obtaining motive power.*"—January 4.

George Child, of Lower Thames Street, Merchant, for "*improvements in the manufacture of bricks and tiles, part of which improvements are applicable to compressing peat and other materials.*" Communicated by a foreigner.—January 4.

John Swindells, of Manchester, Manufacturing Chemist, for "*improvements in the manufacture of artificial stone, cement, stucco, and other similar compositions.*"—January 6.

William Newton, of Chancery Lane, Civil Engineer, for "*certain improvements in looms for weaving.*" Communicated by a foreigner.—January 9.

John Rock Day, of Great Queen Street, Lincoln's Inn Fields, Sadlers' Ironmonger, for "*improvements in the construction of collars for horses and other draft animals.*"—January 6.

Henry Gunter, of Cullum Street, Fenchurch Street, Merchant, for "*improvements in preserving animal and vegetable substances.*"—January 6.

Henry Bessemer, of Perceval Street, Clerkenwell, for "*a new mode of checking the speed of or stopping railroad carriages under certain circumstances.*"—January 6.

William Thompson, of Upper North Place, Gray's Inn Road, Brush Maker, for "*improvements in the construction and mounting of various kinds of brushes and brooms.*"—January 8.

William Lacey, of Birmingham, Agent, for "*certain combinations of vitrified and metallic substances applicable to the manufacture of ornaments, and the decoration and improvements of articles of domestic utility and of household furniture, also applicable to church windows and shop lights.*"—January 11.

Matthew Uzielli, of King William Street, Merchant, for "*improvements in impregnating and preserving wood and timber for various useful purposes.*" Communicated by a foreigner.—January 11.

William Newton, of Chancery Lane, Civil Engineer, for "*improved machinery for cleaning wheat and other grain or seeds from smut and other injurious matters.*" Communicated by a foreigner.—January 11.

John Barwise, of Saint Martin's Lane, Chronometer Maker, and Alexander Bain, of 35, Wigmore Street, Cavendish Square, Machinist, for their invention of "*improvements in the application of moving power to clocks and time pieces.*"—January 11.

Thomas Harris, of Chiffnal, Salop, for "*an improved horse-shoe.*"—January 11.

Joseph Hall, of Cambridge, Grocer and Draper, for "*a seed and dust disperser, applicable to the freeing of corn and other plants from insects.*"—January 14.

Walter Hancock, of Stratford-le-Bow, Essex, for "*an improved means of preventing accidents on railways.*"—January 14.

Pierre Armand Le Comte de Fontainemoreau, of Skinner Place, Size Lane, for "*an improved machinery for carding and spinning wools and hairs, which he titles "Filo Finisher.*" Communicated by a foreigner.—January 14.

Melcher Gakner Todd, of the island of Saint Lucia, for "*a certain improved form of apparatus for the distilling and rectification of spirits.*"—January 14.

John Loach, of Birmingham, Brass Founder, for "*improvements in castors applicable to cabinet furniture and other purposes.*"—January 14.

William King Westley, of Leeds, Flax Merchant, for "*improvements in carding, combing, straightening, cleansing, and preparing for spinning hemp, flax and other fibrous substances.*"—January 14.

William Kenworthy, of Blackburn, Spinner, and James Bullough, of the same place, Overlooker, for "*improvements in machinery, or apparatus for weaving.*"—January 14.

Charles Cameron, Esquire, of Mount Vernon, Edinburgh, for "*improvements in engines, to be actuated by steam and other elastic fluids.*"—January 14.

Samuel Hall, of Basford, Nottingham, Civil Engineer, for "*improvement in the combustion of fuel and smoke.*"—January 14.

Alexander Jones, of King Street, London, Engineer, for "*improvements in the manufacture of copper tubes and vessels.*"—January 14.

Edward Foard, of Queen's Head Lane, Islington, Machinist, for "*an improved method, or improved methods, of supplying fuel to the fire-places or grates of steam-engine boilers, brewers' coppers, and other furnaces, as well also to the fire-places employed in domestic purposes, and generally to the supplying fuel to furnaces or fire-places, in such a manner as to consume the smoke generally produced in such furnaces or fire-places.*"—January 16.

John Ames, of Plymouth, Painter, for "*a new and improved method of making paint from materials not before used for that purpose.*"—January 16.

James Smith, of Deanston Works, Kilmadock, Perth, Cotton Spinner, for "*certain improvements in the preparing, spinning, and weaving of cotton, silk, wool, and other fibrous substances, and in measuring and folding woven fabrics, and in the machines and instruments for these purposes.*"—January 19.

Thomas Robinson, of Wilmington Square, Middlesex, Esquire, for "*improvements in drying woollen and other fabrics.*"—January 19.

Thomas Vaux, of Frederic Street, Gray's Inn Lane, Worsted Manufacturer, for "*improvements in horse-shoes.*"—January 19.

Caleb Bedells, of Leicester, Manufacturer, Christopher Nickell, of York Road, Lambeth, Gentleman, and Archibald Turner, Foreman to the said Caleb Bedells, for "*improvements in the manufacture of braids and plats.*" Partly communicated by a foreigner.—January 19.

John Barber, of Manchester, Engraver, for "*improvements in machinery, for the purpose of tracing or etching designs or patterns on cylindrical surfaces.*"—January 19.

Frederick Steiner, of Hyndburn Cottage, Lancaster, Turkey Red Dyer, for "*improvements in looms for weaving and cutting asunder double-piled cloths, and a machine for winding weft to be used therein.*" Communicated by a foreigner.—January 19.

John Cox, of Georgie Mills, Edinburgh, Tanner, for "*improvements in apparatus for assisting or enabling persons to swim or float, or progress in water.*"—January 19.

Charles Berwick Curtis, of Acton, Esquire, for "*methods to be used on railways for the purpose of obviating collisions between successive trains.*"—January 19.

Angier March Perkins, of Great Coram Street, Engineer, for "*improvements in apparatus for heating by the circulation of hot water, and for the construction of pipes and tubes for such and other purposes.*"—January 21.

John Melville, of Upper Harley Street, Esquire, for "*improvements in propelling vessels.*"—January 21.

William Hill Darker, senior, and William Hill Darker, junior, both of Lambeth, Engineers, and William Wood, of Wilton, Carpet Manufacturer, for "*improvements in looms for weaving.*"—January 21.

John Bradford Furnival, of Street Ashton, Warwick, Farmer, for "*improvements in the construction and application of air-vessels.*"—January 21.

William Cooper, of Layham, Suffolk, Iron Founder, for "*an improved method of constructing thrashing-machines and other agricultural instruments.*"—January 21; two months.

Isham Baggs, of Cheltenham, Gentleman, for "*improvements in printing.*"—January 23; six months.

Peter Fairbairn, of Leeds, Engineer, and William Suthill, of Newcastle-upon-Tyne, Flax Spinner, for "*improvements in drawing flax, hemp, wool, silk, and other fibrous substances.*"—January 26.

Edward Henshall, of Huddersfield, Carpet Manufacturer and Merchant, for "*improvements in making, manufacturing, or producing carpets or hearth-rugs.*"—January 26; four months.

Nathaniel Lloyd, of Manchester, and Henry Robotham, of the same place, Calico Printer, for "*improvements in thickening and preparing colours for printing calicoes and other substances.*"—January 26; six months.

Nathan Waddington, of Hulme, Lancaster, Engineer, for "*improvements in the construction of steam-boilers, and furnaces for heating the same.*"—January 26.

Cornelius Alfred Jacquin, of Huggin Lane, for "*improvements in the manufacture of covered buttons, and in preparing of metal surfaces for such manufacture, and other purposes.*"—January 26.

John Bradford Furnival, of Street Ashton, Farmer, for "*improvements in evaporating fluids, applicable to the manufacture of salt, and to other purposes where evaporation of fluids is required.*" Communicated by a foreigner.—January 26.

Richard Jenkyn, of Hoyle, Cornwall, Machinist, for "*improvements in valves for hydraulic-machines.*"—January 26.

William Gall, of Beresford Terrace, Walworth, Gentleman, for "*improvements in the construction of locomotive engines, and of the carriages used on railways, applicable in part to carriages used on common roads.*" Communicated by a foreigner.—January 28.

William Currie Harrison, of Newland Street, Eaton Square, Pimlico, Engineer, for "*an improved turning-table for railway purposes.*"—January 28.

Joseph Pryor, of Wendron, Cornwall, Builder, for "*an improved thrashing-machine.*"—January 28.

TO CORRESPONDENTS.

The drawing of a "Wood Bridge over the River Calder," will appear next month.

J. Cook *on the Curvature of the Arches of the Holy Trinity at Florence, will appear in the next Journal.*

We feel obliged to C. H. W. *for his communications; we will avail ourselves of them at an early opportunity; he will perceive that we have already taken advantage of one of them.*

We shall be happy to hear again from our Dublin correspondent.

H *in reply to* Eder *was received too late; it shall appear next month.*

We must apologize to several correspondents who have written to us for information, for not answering them; if they were aware of the numerous communications that are addressed to us, they would not be surprised at not hearing from us. If we are in possession of the information, without the necessity of going to others for it, we shall at all times feel much pleasure in answering their inquiries.

Books received too late for notice this month:—Trotter's Manual of Logarithms and Practical Mathematics; Architectural Precedents with Specifications and Working Drawings; Alderson on the Steam Engine; The Derby Arboretum.

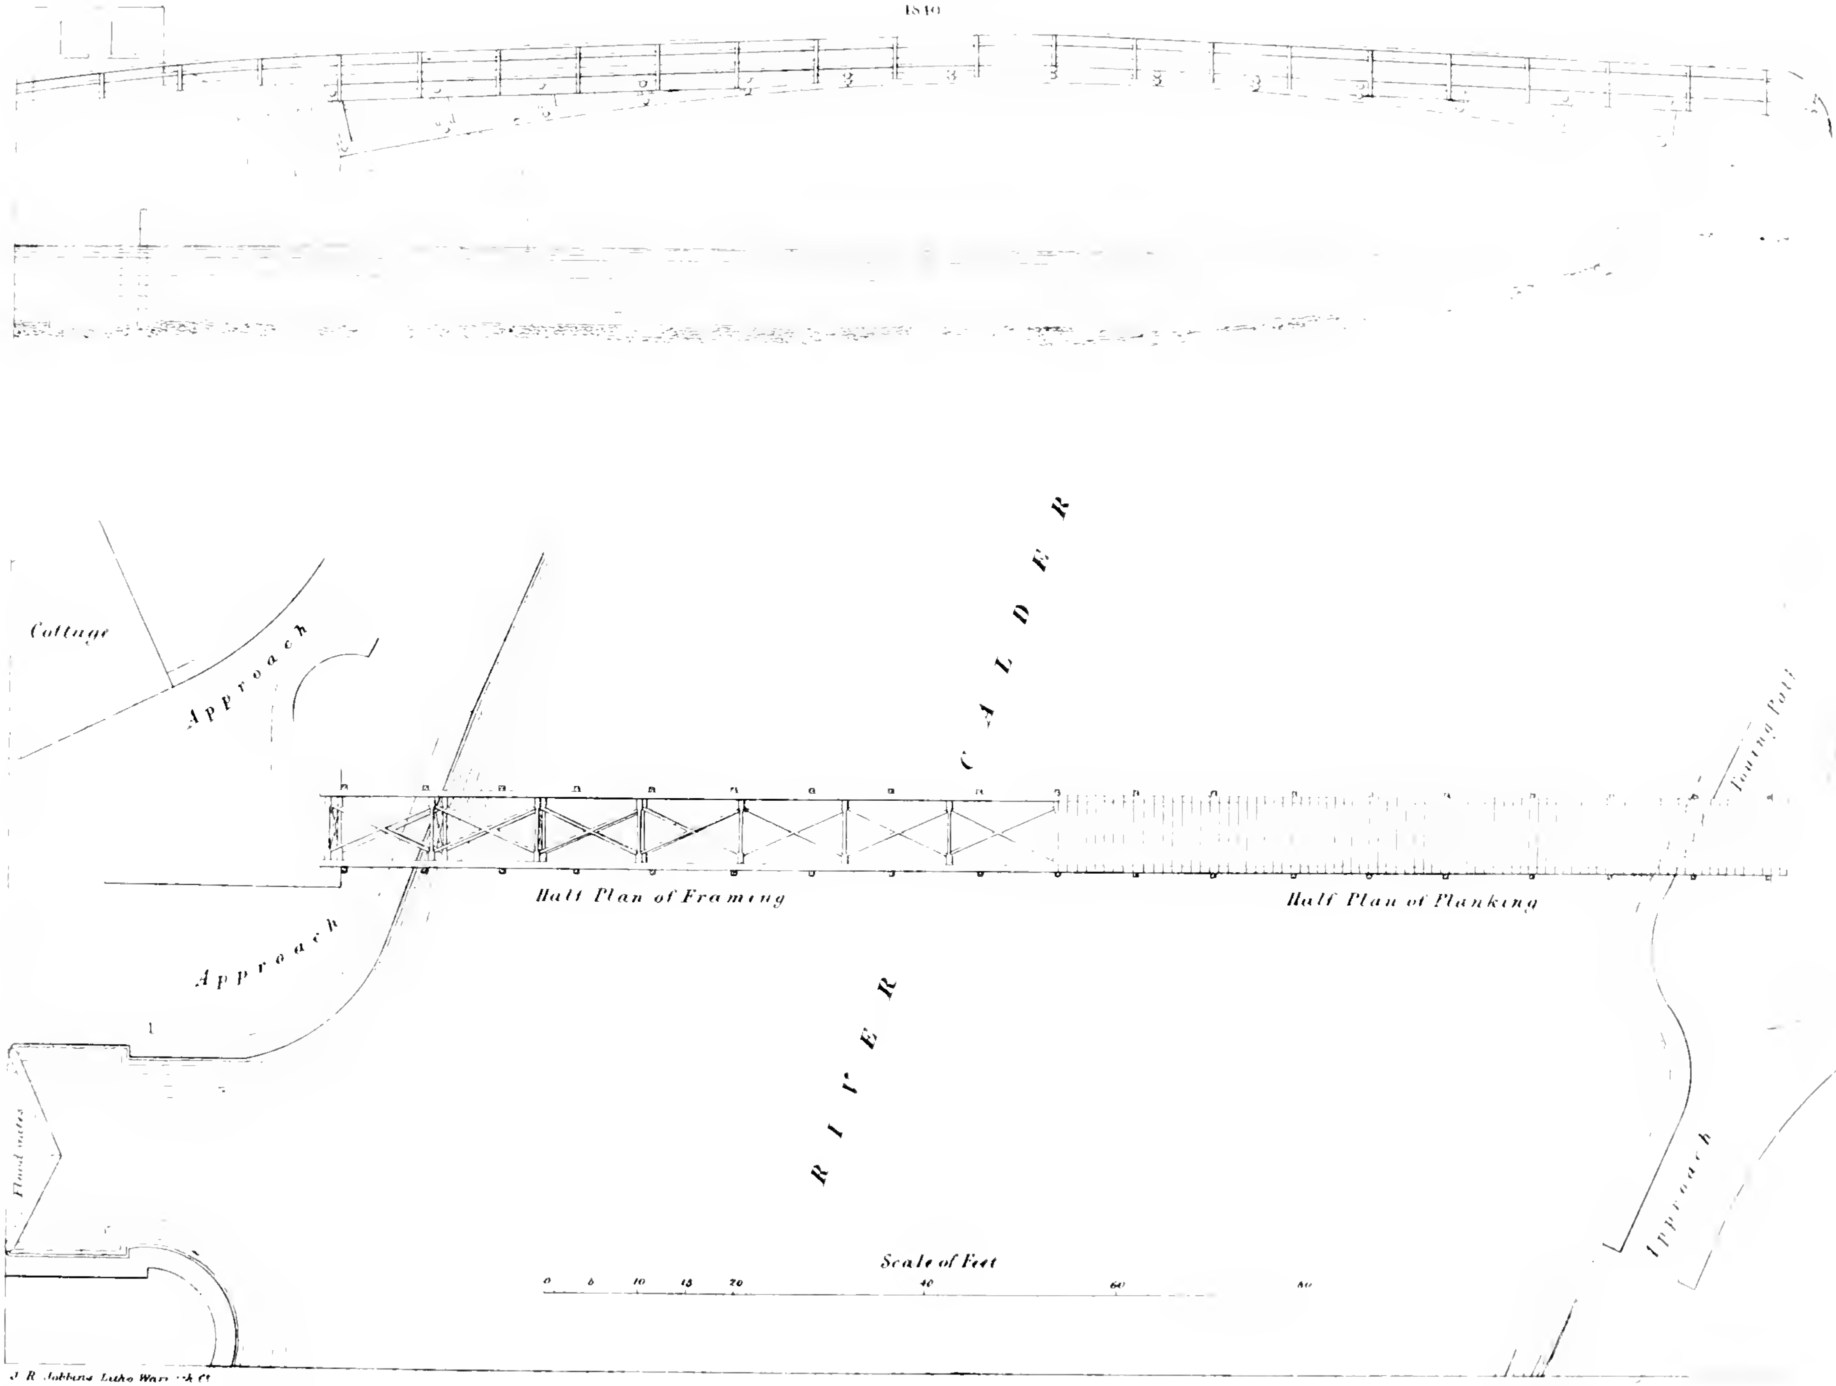
Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No. 11, Parliament Street, Westminster.*

Books for review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume.

By William Bull Civil Engineer.

1840



WOOD BRIDGE OVER THE RIVER CALDER, NEAR COOPER BRIDGE, YORKSHIRE.

For the use of the Hauling Horses on the Calder and Hebble Navigation. 1840.

(With an Engraving, Plate 3.)

William Bull, Engineer.

The span of this bridge is 150 feet, the versed sine of the arch 8 feet, and the width of the roadway 8 feet. The abutments are composed of solid masses of ashlar and rubble masonry. The arch consists of two ribs of fir timber with cross and diagonal framing pieces, as shown in the plan. The roadway is formed of 3 inch deal planks, over which is laid a coat of pitch, tar, and gravel mixed, and laid on hot to about one inch in thickness. The ribs are formed of two thicknesses of timber in pieces of about 21 feet long each, and laid on each other so as to break joint at each cross brace, where they are properly secured together by vertical and horizontal (cross) wrought iron bolts. The cross bolts having cast iron washers of about ten inches diameter at each end, and the vertical bolts, which are in pairs, are connected by two short straps of flat iron at the top and bottom of the ribs, the straps passing across the joints of the wood. The scantlings of the ribs are as follows: at the crown of the arch 2 ft. 2 in. by 9 in., at the abutments 3 ft. by 9 in. in two equal parts of 18 inches deep each, connected by vertical struts 13 inches by 6 inches, having the upright connecting bolts, one on each side of the struts.

The cost of the abutments, including the approaches at each side, which are made so that the horses can pass, first under, and then over, the bridge, so as to obviate the necessity of casting loose the hauling lines, was about £500, and of the arch about £170, making a total cost of about £1070.

The appearance of this bridge is extremely light and elegant, while the strength and stiffness is far more than adequate to the purpose for which it is intended.

The whole of the woodwork has gone under the Kyanizing process after it was framed, and is, besides, either tarred or painted.

THE DERBY ARBORETUM.

Fig. 1.—One of the Pavilions forming the Terminations to the cross Walk. Style of James I.

[It affords us much pleasure to be able to give the following description by Mr. Loudon of the Derby Arboretum, which was opened during last summer; it is the munificent gift of a private individual, whose patriotic example we sincerely hope will be followed by many other individuals. Mr. Strutt not only gave the land, but also engaged Mr. Loudon, one of the first Landscape Architects of the day, to lay out the grounds, and render them suitable to the purposes intended, which Mr. Loudon has done to the admiration and satisfaction of all parties.]

The situation is in the outskirts of the town; the extent about 11 acres; the form long, narrow, and irregular, as shown by the plan, fig. 2; the surface is flat, apparently level, but with a very gentle inclination from the north-east to the south-west; and the soil is loamy, on a gravelly or loamy subsoil. The situation is open, but not much exposed to high winds; water is to be found at the usual depth to which wells are dug, and there is one small pond which is never dry at any period of the year. Every part of the ground admits of drainage; but all the drains must terminate at the south-east corner, where alone the water can escape. The soil is particularly well adapted for the growth of trees, as is evident from the belt which surrounds great part of the grounds, and which was planted some years ago by Mr. Strutt. The most important feature in this piece of ground, with reference to its adaptation for a garden of recreation, is, that there is no distant prospect, or view beyond the grounds, worthy of being taken into consideration in laying them out; or at least none that may not, in a very few years, be shut out by the buildings of the town, which are increasing fast on every side.

The instructions given to me by Mr. Strutt respecting laying out this public garden were, that it was intended to be a place of recreation for the inhabitants of Derby and the neighbourhood, and for all other persons who chose to come and see it; that it should be open two days in the week, and that one of these days should be Sunday, during proper hours; and that on other days a small sum should be required from persons entering the garden; or yearly admissions should be granted for certain moderate sums. That the gardens should be so laid out and arranged as not to be expensive to keep up; that a flower garden and cottage, with the plantations already existing, should, if possible, be preserved; that a tool-house covered with ivy should also be preserved; that two lodges with gates, at the two extremities, should be built; and that each lodge should have a room, to be considered as a public room, into which strangers might go and sit down, taking their own refreshments with them, without any charge being made by the occupant of the lodge, unless some assistance, such as hot water, plates, knives and forks, &c., were required, in which case a small voluntary gratuity might be given. That there should be proper yards and conveniences at each lodge for the use of the public, apart from those to be exclusively used by the occupant of the lodge. That there should be open spaces in two or more parts of the garden, in which large tents might be pitched, a band of music placed, dancing carried on, &c. That certain vases and pedestals now in the flower-garden, and also certain others in Mr. Strutt's garden in Derby, should be retained or introduced; and, finally, that some directions should be left for the management of the garden.

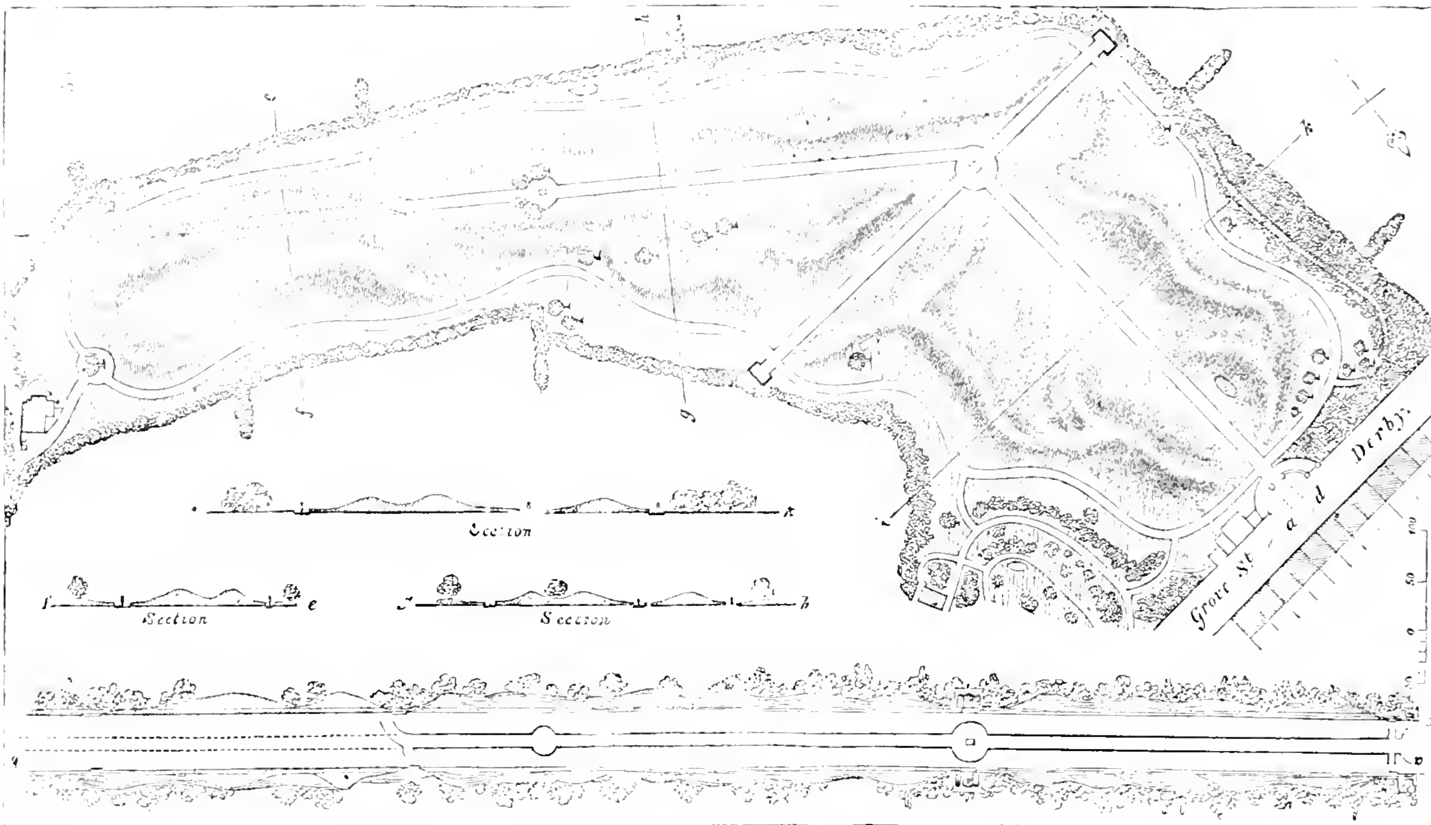
REASONS FOR THE MAIN FEATURES OF THE PLAN.

In endeavouring to accommodate the design submitted to Mr. Strutt to his instructions and to the situation, the first point determined on was, that the whole interest of the garden should be contained within itself. The mode of doing this was next to be considered; when it appeared that a general botanic garden would be too expensive, both to create and to keep up; that a mere composition of trees and shrubs with turf, in the manner of a common pleasure-ground, would become insipid after being seen two or three times; and, in short, that the most suitable kind of public garden, for all the circumstances included in the above data, was an arboretum, or collection of trees and shrubs, foreign and indigenous, which would endure the open air in the climate of Derby, with the names placed to each. Such a collection will have all the ordinary beauties of a pleasure-ground viewed as a whole; and yet, from no tree or shrub occurring twice in the whole collection, and from the name of every tree and shrub being placed against it, an inducement is held out for those who walk in the garden to take an interest in the name and history of each species, its uses in this country or in other countries, its appearance at different seasons of the year, and the various associations connected with it.

A similar interest might, no doubt, have been created by a collection of herbaceous plants; but this collection, to be effective in such a space of ground, must have amounted to at least 5000 species; and to form such a collection, and keep it up, would have been much more expensive than forming the most complete collection of trees and shrubs that can at present be made in Britain. It is further to be observed respecting a collection of herbaceous plants, that it would have presented no beauty or interest whatever during the winter season; whereas, among trees and shrubs, there are all the evergreen kinds, which are more beautiful in winter than in summer; while the deciduous kinds, at that season, show an endless variety in the ramification of their branches and spray, the colour of their bark, and the colour and form of their buds. Add also, that trees and shrubs, and especially evergreens, give shelter and encouragement to singing birds, to which herbaceous plants offer little or no shelter or food.

There are yet other arguments in favour of trees and shrubs for a garden of recreation, which are worth notice. Herbaceous plants are low, small, and to have any effect must be numerous; while, to acquire their names, and look into their beauties, persons walking in the gar-

Fig. 2—Plan of the Arboretum.



den must stand still, and stoop down, which, when repeated several times, would soon, instead of a recreation, become very fatiguing. Now trees and shrubs are large objects, and there is scarcely one of them the beauty of which may not be seen and enjoyed by the spectator while he is walking past it, and without standing still at all. A herbaceous plant is chiefly interesting for its flowers, and the form of its foliage, in which in general there is little change of colour; but, to these two sources of interest, trees and shrubs add the opening buds in spring, the colour of the expanded foliage immediately after it has burst from the bud, the fine green tinged with some other colour which the first leaves assume when they are fully expanded, and which continues more or less till the middle of June; the intensely deep green of summer, which continues till the end of July; the first changes of autumn to red or yellow, which commence in August; and the dying off of all the different shades of red, crimson, yellow, orange, brown, and purple, which continues taking place till Christmas; while some deciduous trees, such as the beech and hornbeam, the common oak in certain soils kept moist, and the *Quércus Taúzin* in all soils and situations, retain their leaves, after they have become brown, till the following May. There are also, in deciduous trees, the colour and bloom of the young shoots of the current year; the different colour which the bark of these shoots in many cases assumes the year following (*Sálix decípiens*, for example); and the colour and texture of the older shoots, and of the branches and trunk. In addition to these sources of interest, there is a very great beauty in trees, which, from the improper planting of artificial plantations, is often overlooked, or rather concealed; and that is, the ramification of the main surface roots at the point where they join the trunk. In general, trees are planted so deep that this ramification never appears above the surface, and the trunk of the tree seems fixed in the ground like a post which had been driven into it; an appearance as contrary to truth and nature, and also to the health of the tree, as the shaft of a column without a base or a capital would, if employed in a building, be to architectural taste. To prevent this monstrous and unnatural appearance from occurring in the Derby Arboretum, I have directed all the trees to be planted on little hills, the width of the base being three times the height of the hill, so that the junction of the main roots with the base of the trunk will appear above ground.

Much more might be said to justify the preference which I have given to an arboretum over every other kind of arrangement for the Derby Garden, but I consider any farther remarks on the subject unnecessary.

A glance at the plan, fig. 2, will show that I have provided as great an extent of gravel walk as he space would admit of; the total length, including the walk round the flower-garden, exceeding a mile. There is a straight broad walk in the centre, as a main feature from the principal entrance; an intersecting broad straight walk to form a centre to the garden, and to constitute a point of radiation to all the other walks; and there is a winding walk surrounding the whole. As a straight walk without a terminating object is felt to be deficient in meaning, a statue on a pedestal is proposed for the radiating centre in fig. 2; a pedestal, with a vase, urn, or other object, for the second circle in the straight walk, fig. 2; while the pavilions, (fig. 1,) form terminating objects to the broad cross walk.

As a terminal object gives meaning to a straight walk leading to it, so it is only by creating artificial obstructions that meaning can be given to a winding walk over a flat surface. These obstructions may either be inequalities in the ground, or the occurrence of trees or shrubs in the line which the walk would otherwise have taken, so as to force it to bend out of that line. Both these resources have been employed in laying down the direction of the surrounding walk, though its deviation from a straight line has chiefly been made in conformity with the varying position of the trees in the belt already existing. This belt, and also the trees in the flower-garden, and in other parts of the plan, which were there previously to commencing operations, and which are left conformably to Mr. Strutt's instructions, are shown in the plan fig. 2. The point of junction of one walk with another is always noticeable in an artistical point of view, and affords an excuse for putting down sculptural or other ornamental objects at these points; we have therefore placed Mr. Strutt's pedestals and vases in positions where, if they are kept properly supplied during summer with pots of flowers (the pot being placed in the inside of the vase so as not to be seen), they will form very ornamental objects; and, the names of the flowers being written conspicuously on a card, and tied round the narrow part of each vase, and the kinds of flowers changed at least once a week, they will be instructive as well as ornamental. The kinds of plants should be such as have conspicuous red or orange flowers, in order to contrast harmoniously with the masses of green foliage and grass with which they are surrounded.

All the walks are drained by semicylindrical tiles laid on flat tiles in

Fig. 3.—Interior View of the main Entrance to the Derby Arboretum. Style Elizabethan.

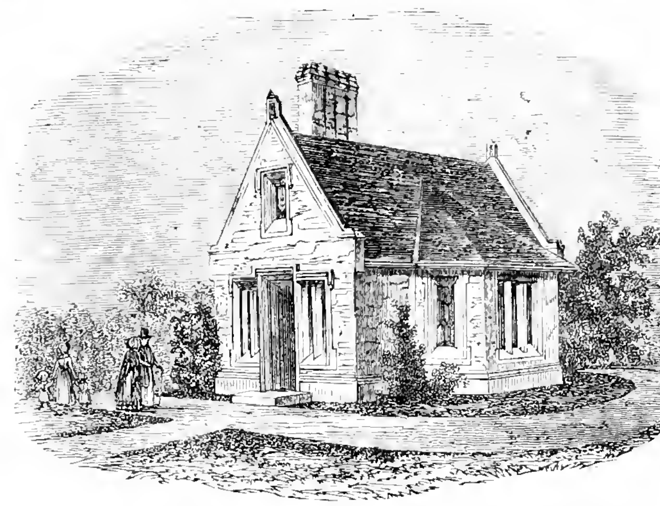


Fig. 4.—East Lodge of the Derby Arboretum, showing the public Room. Tudor Style, time of Henry VII.

a line along the centre of the walk, and by cross drains from this line to the edges of the walk, communicating with gratings fixed in stone at regular distances. There is nearly a mile of drains, and there are 150 cast iron gratings. The upper coating of gravel is of a good colour, brownish yellow; and, as when kept in proper order by rolling it binds very hard and smooth, the walks will be of the most dry, comfortable, durable, and agreeable description.

In order to disguise the boundaries of the ground, and to conceal the persons walking in the side walks from those in the centre walks, I have raised undulating mounds of soil, varying in height from 7 feet to 10 feet, in the directions indicated by the shadows in fig. 2; and these, even without the aid of the trees and shrubs which are planted on them, effectually answer the ends proposed. Certain spaces on the lawn throughout the garden are left perfectly smooth and level, on which tents may be fixed, or parties may dance, &c. I should have made certain hollows and winding hollow valleys, as well as the hills and winding ridges; but the retentive nature of the soil, the difficulty, or rather the absolute want, of drainage for such hollows, as well as the very limited space, and the necessity of having a broad, straight, nearly level walk down the centre, rendered this impracticable.

In moving the ground, care has been taken to preserve some of the old surface soil to form the new surface; and this new surface has also been drained where necessary, and every where rendered perfectly smooth and even, by raking and rolling, before sowing the grass seeds.

The seats have been designed and placed, chiefly by Mr. Strutt himself, reference being had to the following rules:—To make choice of situations under the shade of trees already existing in the belts, or of situations where some kind of view or feature is obtained; to place some in gravelled recesses along the sides of the walks, and others on the turf; some open to the sun for winter use; but the most part looking to the east, west, or north, for summer use. Those seats which are placed in recesses ought to be 1 foot back from the edge of the walk, in order that the feet of persons sitting on them may not be in the way of passers by; and the gravelled recess should extend 6 inches beyond the seat behind and at each end, for the sake of distinctness, and to prevent any difficulty in weeding the gravel or mowing the grass. No seat should be put down, along the walks, in such a situation as to allow persons approaching it to see the back of the seat before they see the front of it; and, hence, the seats should generally be placed in the concavities of the turns of walks rather than in the convexities of bends. No seat to be put down where there is not either a considerable space directly in front, or at an angle of 45°, or some other equal and large angle on each side. No seat to be put down where there will be any temptation to the persons sitting on it to strain the eye looking to the extreme right or left. None to be put down where more than one point of the boundary of the garden can be seen from the seat. None to be put down on the tops of the mounds, by which a person sitting would, at least before the trees and shrubs grow up, get a panoramic view of the entire garden, and thus defeat the main object of the mounds, and of the winding direction of the side walks. No seat to be put down, nor any device contrived, by which both the lodges can be seen at once from the same point of view; or even where one of the lodges and one of the pavilions can be seen from the same seat. Seats which are placed on the lawn always to be backed by some of the trees or shrubs there, so that no person may ever come close up to a seat from behind; or, if seats are placed in the open lawn without trees or shrubs near them on either side, then such seats must be made double, with a common back in the centre, or they may be benches without backs, or single seats, such as chairs or stools. All fixed seats, whether on the lawn or on gravel, to have foot-boards for the sake of aged persons and invalids. Round the central circle the seats should have stone backs, and a more architectural character than in any other part of the garden.

The flower-garden with its covered seat, the cottage in it with its public tea-room, and the ivied tool-house formerly attached to Mr. Strutt's kitchen-garden, are preserved; and also a a large weeping ash with seats beneath, the branches of which have been trained into a regular form by iron rings

In order to design the entrance lodges and gates, and the central statue, I called in the aid of Mr. E. B. Lamb, M.I.B.A., whose designs for the lodges and gates are shown in fig. 3, 4, and 5, and the ground plans of which are in accordance with Mr. Strutt's instructions in regard to public rooms, yards, and other accommodations. It may be added that the design of the garden will not be complete without an obelisk, or some such object, in the centre of the radiating circle in fig. 1; but this part of the plan is left to be completed by the committee of management.

As my instructions were to preserve as much as possible the belt and the trees in the interior of the ground already existing, I considered it most convenient to adopt the surrounding walk as a line of demarcation between the collection or arboretum in the interior of the grounds, and the miscellaneous assemblage in their circumference. Had the belt not existed, I should have extended the arboretum over the ground occupied by it, and thus have obtained room for a greater number of species, and a larger space for each individual tree and shrub. As things are, I have extended the belt in those places where it was wanting, and added to its interest by evergreen undergrowths, such as rhododendron, kalmia, laurustinus, box, holly, and mahonia; by low trees, such as arbor vitæ, red cedar, and cypress; and by large trees, such as cedar of Lebanon, silver fir, hemlock spruce, and evergreen oak. I have also introduced a collection of 100 different kinds of roses, all named; and placed the genera *U'lmus*, *Quércus*, *Pópulus*, and *Sàlix* in the new part of the belt, in order to give more room in the interior.

All the ground not covered by trees or shrubs I have directed to be laid down in grass to be kept closely mown; but round each tree and shrub forming the collection I have preserved a circular space, varying from 3 feet to 5 feet in diameter, which (with the hill in the centre, comprising one-third of the width of the circle, and on which the plant is placed) is not sown with grass, but is always to be kept clear of weeds. The use of this circle and little hill is to prevent the grass from injuring the roots of the trees while young, and to admit of the larger roots showing themselves above the surface, where they ramify from the stem, as before mentioned. It has been found since the garden was completed that these little hills have served as an effectual preservative of the plants; because, notwithstanding the many thousands of persons that visited the garden during the three days of the

Fig. 5.—East Lodge of the Derby Arboretum, showing the Entrance Gates. Tudor Style, time of Henry VII.

ceremony of the opening, not a single plant was injured. Some few of the shrubs which require peat soil, such as the heaths, have had that soil prepared for them; and the genera *Cistus* and Heliánthemum, which are apt to damp off on a wet surface, are planted on a raised mass of dry rubbish, covered with stones. All the climbing plants have upright iron rods, with expanded umbrella-like tops, placed beside them; the lower end of the iron rod being leaded into a block of stone, and the stone set in mortar on brickwork, so that the upper surface of the stone appears 1 inch higher than the surrounding surface. This appearance of the stone above the surface is not only more architectural and artistical, but better adapted for the preservation of the iron at the point of its junction with the stone, than if the stone were buried in the soil.

With respect to the annual expense of keeping up the garden, it will be evident to those who have seen it, or who understand this description, that it will chiefly consist in mowing the grass in the summer season. As the extent of grassy surface to be mown will be reduced by the space occupied by the walks, and by the circles of earth on which there is no grass (on which the trees and shrubs stand, or which those in the belt cover entirely), to about six acres, one man will be sufficient to mow and sweep up this extent of lawn during the whole summer; the daily space to mow being about half an acre, and the grass mown to be distributed over the naked circles on which the trees and shrubs stand. All the other work which will require to be done in the garden during summer, such as weeding the walks, rolling them, weeding the circles on which the trees and shrubs stand, picking off insects from the plants, watering the ground with lime water where worm-casts appear, wiping the seats every morning so as to remove the excrement of birds, or whatever leaves or other matters may drop from the branches of the trees over them, &c. &c., may be accomplished by a second labourer. The head gardener or curator may manage the flower-garden and the vases of flowers at the junctions of the walks, and see that the company who walk in the garden do not injure the plants, &c.

During the winter season, or from December 1, to May 1, more than one labourer in addition to the head gardener will be unnecessary. The second labourer may at that season, therefore, be allowed to retain his house, and seek for labour elsewhere; and the saving thus made, it is presumed, would be a contribution towards the purchase, from some of the Derby nurserymen or florists, of all the flowers or other plants that may become necessary to fill the vases from May till October. Unless some arrangement of this sort be made, it will be impossible to do justice to the plan of exhibiting plants in the vases; because the flower-garden, if made a source of supply, would be injured in appearance; and to have a reserve garden, with a green-house or pit, would involve much more expense than hiring the plants from a nurseryman, and would be far from attaining the object in view so effectually. On the supposition that there were fifty vases, there would then be fifty different kinds of named flowers or green-house plants in them every day during the summer; and supposing that these kinds were changed once a week, and the same kind not repeated more than once in the same season, there would then have been upwards of 500 different kinds of handsome plants, with their names attached, exhibited to the public in the course of a single year. To give an idea of what these plants might be, I shall suppose them to consist of 200 showy hardy and tender annuals, 100 dwarf dahlias, 100 choice herbaceous plants, 100 geraniums, 100 Australian plants, 50 heaths, and 50 miscellaneous green-house plants, including fuchsias, cacti, aloes, &c. One great use of these plants is, by their bright red, yellow, orange, or white colours, to relieve the eye, and form a contrast to the green of the foliage and grass with which they are surrounded on every side. A similar contrast will be obtained by the colours of the dresses and countenances of persons walking in the Arboretum.

The plan of the Arboretum was made in May, 1839; and, being approved of by Mr. Strutt, as soon as the crop of hay was removed from the ground, in the July following, the work was commenced by Mr. Tomlinson, a contractor for ground work, who laid out the walks, made the drains, and raised the general masses of the mounds. The mounds were afterwards moulded into suitable shapes, and connected by concave sides and lateral ridges with the surrounding surface, under the direction of my assistant, Mr. Rauch, who also superintended the planting of all the trees and shrubs, and all the other details connected with the ground, till the completion of the whole in September, 1840. The trees and shrubs were supplied chiefly by Messrs. Whitley and Osborn, but partly also by Mr. Masters of Canterbury; and the miscellaneous collection of roses was furnished by Mr. Rivers of Sawbridgeworth; the mistletoe was supplied by Mr. Godsall of Hereford; and some species, which could not be procured in the nurseries, were obtained from the Horticultural Society's Garden. The lodges and pavilions were designed by Mr. Lamb, as already mentioned: the north, or main, lodge in the Elizabethan style; the east lodge in the Tudor style, and in that variety of this style which was prevalent in the time of Henry VII.; and the pavilions in the style of James I. They were all built by Mr. Thompson of Derby; and the gates to the north, or principal, lodge were cast from Mr. Lamb's designs by Messrs. Marshall, Barber, and Co., of Derby.

ARCHITECTURAL COMPETITION.

Sir—The spirited manner in which you acted respecting the proceedings of the Gresham Committee in their attempt to extort the sum of one pound from architects desirous of competing for the Royal Exchange, and for which you received a vote of thanks from the Manchester Architectural Society, in which I (being a member) heartily concurred, has induced me to forward you the enclosed advertisement, which appeared in the Times newspaper, in compliance with which I wrote to the Vicar for the necessary particulars, and received in answer the accompanying note, by which it appears that the Vicar and Churchwardens are following the notable example of the Gresham Committee. Surely if the demand of twenty shillings for the necessary instructions was an extortionate act of the Gresham Committee, how much more so is the same demand in this case, where even the successful competitor is only to receive his commission upon £1,000, instead of the much larger sum at stake in the case of the Royal Exchange.

I leave you to comment upon this subject (should you think it worth notice in your valuable Journal), in any way you deem proper, but I think you will agree with me that the practice of charging architects *anything*, be the sum either large or small, for the instructions necessary in the preparation of competition designs, is very impolitic and reprehensible, and one that ought to be most strongly protested against by the profession.

The loss of time and expense architects must necessarily incur one would imagine quite sufficient for the most exacting Committee, without having new burdens continually heaped upon them.

I am, Sir,

An occasional Competitor.

February 8, 1841.

The following is the advertisement and letter referred to by our correspondent:—"Architects desirous of submitting plans for the new pewing of the church of Fordingbridge, Hants, may apply to the Vicar and Churchwardens of Fordingbridge, until the 16th day of January next."

"The Vicar and Churchwardens in reply to A. B.'s letter, beg to inform him that the plans for repewing the Church of Fordingbridge, must be sent in by the 26th of February, and be in strict accordance with the instructions of the Church Building Society, but the estimate must not exceed £1,000.

"A lithographic ground plan is now ready to be forwarded on the remittance of a Post-office order for £1.

"A motto must be inscribed on the plan, and also a sealed letter enclosing the name of the candidate."

Fordingbridge, Jan. 20, 1841.

EPISODES OF PLAN.

"*Tædet quotidianarum harum formarum.*"

That there should be any thing at all novel in our manner of treating the subject we have chosen,—that the same idea should not have presented itself to others, and have been frequently adopted and carried out in publications bearing upon the particular branch of architectural study towards which this series will, we trust be found to contribute something fresh,—that such should be the case causes us no small surprise. Yet that we have not been anticipated in our present task by any one else, we may venture to affirm with tolerable confidence, since in none of the architectural works, either English or Foreign, we have seen—and our acquaintance with them is tolerably extensive—have we ever met with any studies of the kind we here purpose bringing forward. Nay the subject itself, as regards *Plan* generally, is almost invariably passed over without the slightest remark of any kind, as if either it were altogether unimportant in respect to design, contrivance, and effect: or as if the merits and defects, the advantages or disadvantages arising out of it were so exceedingly obvious to every one as to render it quite unnecessary to call attention to circumstances of that kind. In regard to Plans it is thought quite sufficient to give the mere explanatory *references* to them, without any thing farther even in the way of descriptive remark: much less are they ever accompanied by any thing like critical examination and comment. The Vitruvius Britannicus and similar works are so far altogether dumb books to the student, leaving him entirely to his own discernment and application, without even so much as putting him in the way of properly and profitably exercising them.

For this neglect of what deserves quite as much attention as almost any thing else in architecture, the only excuse that can be alleged—and a most unsatisfactory and provoking excuse it is—is that the plans themselves are so exceedingly common-place and insipid as scarcely to afford any matter at all for remark. We can learn from them the number and dimensions of the rooms, and beyond that there is very rarely any thing whatever in a plan that claims particular notice: for scarcely ever do we meet with a single piquant and *effectful* Episode. As seldom, too, do we find aught very original or particularly happy in the general combination—in what may be called the *laying out* of a building, generally. Instead of perceiving diligent study in this respect, we far more frequently detect—or rather, are struck by defects that seem to have originated in sheer negligence and inattention, they being such as could hardly ever have been suffered to pass, had the drawings been duly revised and reconsidered for the purpose of ascertaining whether they were susceptible of improvement. Laugier's remarks as to the extreme importance and value of Plan, are so excellent that they ought to be written in letters of gold, and hung up in every school of architecture,—certainly to be noticed in every elementary course of the study; and yet the advice they contain is either unknown or disregarded, which circumstance is rather a discouraging one to ourselves, inasmuch as it indicates what little attention is paid to, or interest is taken in what we have here selected as our subject.

Another writer, Milizia, reproaches architects with the monotonousness of their plans, and with scarcely ever deviating from the most "quotidian forms." With here and there a solitary exception, as he remarks, all our rooms—the most sumptuous as well as the most ordinary ones—are rectangular both in plan and profile; that is, are spaces enclosed only by four walls, and covered by a flat ceiling; consequently variety is reduced to little more than that which can be obtained by means of size and proportion, in regard to which there can be comparatively little difference in any suite of principal apartments in a house. For diversity of character, therefore, rooms are, in general, made to depend solely upon fitting-up, decoration, and furniture—matters which, as usually managed, are hardly considered to belong to the architect's province at all. In regard to what is strictly understood by the architecture of a room, variety of design seldom extends beyond what may be called mere *pattern;* the general forms being in every case the same, let them differ as they may in regard to detail. We are far from denying that considerable difference of character is attainable even according to the usual practice; but then it is obvious that such difference might be increased in geometrical ratio, by adopting forms that would lead to an infinity of combinations.

The system hitherto pursued in laying out—not ordinary houses, but mansions where we might expect to meet with all the graces of interior architecture, is calculated to produce only the minimum of effect; and what little effect it admits of is generally misplaced, being bestowed not on the apartments themselves, but merely on the approach to them. Far more frequently than not, such parts as entrance halls and staircases are both more spacious and more striking—both more architectural and more picturesque than any others; and in comparison with them, the rooms to which they lead, seem quite commonplace—not to say insignificant.* The consequence is, a most unfortunate anti-climax. That the first coup d'œil on entering should be a favourable one, and impressive in itself, we readily grant; still what is so shown should be treated as only preparatory—as something intended to excite curiosity, and not as a magnificent promise followed by nonperformance and disappointment. There ought at least to be something of equal value kept in reserve, so as, at any rate to keep up a balance, if no more; whereas the contrary mode may not inaptly be described as a sort of bathos in architectural composition,—as the reverse of a *crescendo* effect,—as a most disagreeable and provoking, because disappointing, hysteron-proteron.

Before proceeding further, it may be as well fairly to meet, knock down, and put *hors de combat* at once those objections which, we foresee, are likely to be brought against the system we ourselves advocate, unless we can show that so far from having overlooked, we have considered, and are prepared to meet them. In the first place it may be urged with some degree of plausibility that if the kind of monotony and sameness which, together with Milizia, we hold to be a defect, were really felt to be such, and on the other hand, the picturesqueness and variety arising out of circumstances of plan and section, were positive merits, pains would be taken to secure the latter, and avoid the former. To this we reply; the constant repetition of the same hackneyed, commonplace forms is looked upon as matter of course: people in general are quite reconciled to it, because they neither look for, nor have any idea of what may be produced by a different mode of treatment. Besides which, the defect is rather negative than positive: a room is not faulty because it is "*quotidian*" in form, and there is nothing particular in it as to design, or that distinguishes it from a thousand others; the fault complained of is, that by confining ourselves to a single idea, as it were, we completely forfeit all those varied effects of which we might avail ourselves. Nor can it be said that the architectural picturesqueness arising out of plan, and general arrangement, is not worth the study it demands, because we have ever found that where it has been produced, it has always struck every one, and made a far greater impression upon them, than mere decoration, however costly. Granting that nothing whatever is gained by it in point of convenience, comfort, or accommodation,—and that a room of the most ordinary shape may be fitted up and furnished quite as splendidly as one which is striking on account of its architectural design;—what then? if any argument against our view of the case is to be derived from that, it may be extended so as to be applied with equal propriety against beauty of proportions in a room, for neither does that conduce to convenience or comfort, nor does the want of it prevent display being made in decoration and furniture.

It will be said, however, that such unusual—or as they will be called very *out-of-the-way* forms as are some of those we intend to bring forward in the course of the present Essay, would be found expensive in execution—perhaps be attended with loss of space, and would hardly admit of being applied without sacrificing other parts of the plan. That they would be more expensive is not disputed: therefore where economy is to be consulted quite as much—if not more than effect, they are of course out of the question; yet on that account they are no more open to censure or cavilling, than porticoes and many other things in architecture, which being of no positive—at least of no urgent utility, may be dispensed with where their cost becomes a serious consideration. It may further be frankly conceded on our part, that to introduce into a plan such features as our Episodes, would demand much more study and contrivance than is required when all that is to be done is to divide it into a given number of squares or parallelograms for the different rooms. To those who complacently satisfy themselves with doing that, and who consider any thing further no better than superfluous *trouble*, no ideas but those of "quotidian" routine are likely to present themselves, let the opportunity for introducing others be as favourable as it may. Hence, we rarely meet with any novelty—or aught striking, in regard to the plan, except in peculiar and obstinate cases, where, owing to local difficulties or other circumstances, the architect has been obliged to humour them, and has thereby been actually compelled to deviate from the ordinary track, and adopt by way of expedient what he would neither have done nor thought of doing, through choice.† Without premeditation, and being brought

* We were lately consulted as to a plan for a very extensive mansion about to be erected, where, on immediately entering the house the visitor sees before him a grand architectural vista of about 300 feet in length,—a most imposing display, no doubt, but produced at the cost of all the rest, for all the rooms would appear little better than cabinets in comparison with it. We accordingly suggested that it would be an improvement, to make a moderate sized entrance vestibule, and reserve the other part as a grand gallery coming at the termination of the suite of reception and drawing rooms.

† It may very fairly be questioned whether the interior of Windsor Castle

in for the [illegible] unusual forms and arrangements are not at all likely to present themselves:—yet a single idea of the kind once adopted readily suggests a second and a third: for the combinations thus to be produced are so illimitable, that the chief perplexity is to decide which of them deserve the preference.

Occasionally, indeed, one meets with plans intended to display novelty and ingenuity, but then so far from being calculated to prepossess in favour of their forms and arrangements, they are seldom better than mere architectural *capriccios*, compounded of extravagant and absurd whims,—merely oddities, in which but little regard is paid either to effect or convenience, consequently they chiefly serve to bring every thing of the kind into discredit, and to confirm the prejudice in favour of common-place routine. Novelty alone will not suffice: there must also be something that will preserve its freshness and will continue to charm when the interest occasioned by novelty shall have worn away.

We are aware there are some who affect to despise any thing like contrivance or scenic effect in architecture, as beneath the dignity of the art—as partaking of stage trickery—as liable to be paltry. They insist upon simplicity, and nothing but simplicity, as if picturesqueness and complexity were never to be admitted, but banished altogether as faults. "Intricate forms, in works of architecture," Professor Hosking tells us, "whether *internally* or externally, will be found unpleasing:" and undoubtedly he is right, if he means no more than to censure that degree of intricacy which becomes confusion—a perplexed architectural jumble that wearies the eye by presenting no one distinct picture, instead of presenting a series of them—all varied, yet all agreeable in themselves and skilfully combined. Most certainly it is not easy to draw a precise line between what is an allowable species of intricacy, and what becomes a faulty excess of it. Yet if no positive rules can be laid down in regard to that quality in architecture, neither can it be done in regard to simplicity, which is apt to be carried so far that it becomes nothing better than poverty, baldness, monotony and insipidity. This is a misfortune which must be patiently submitted to; though, for our own part, we question its being one at all; since there would be small merit in going right, if it were impossible to go astray; nor would, we apprehend, the dignity of art be consulted by reducing art to such a system of exact rules for every possible occasion and contingency, that it might be learnt by rote. Of mechanical rote and routine there is by far too much in architecture already. It is true routine must be learnt and gone through: yet that is no reason wherefore we should confine ourselves to it without endeavouring to get a step beyond it. Rules are excellent leading-strings for beginners, yet little better than shackles to the more advanced artist.

(To be continued.)

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXIV.

> "I must have liberty
> Withal, as large a charter as the winds,
> To blow on whom I please."

I. The terms in which they are sometimes spoken of, might lead those who had never seen them, to imagine that our London Squares possessed a high degree of positive architectural beauty, or at least were strikingly picturesque: neither of which is by any means the case. To apply, as has been done before now, the epithet "magnificent" to them, might almost pass for malicious, sneering irony, did we not know that if not bestowed, out of serious conviction, it is at least intended to be understood in earnest;—and such prodigality of praise, most certainly costs the dealers in "flummery" description nothing, it being just as easy to write the word "magnificent" as any other. The sober truth is, our Squares are very agreeable places of residence, and the houses in them are generally of a superior kind to others in their neighbourhood; they are more pleasantly situated, enjoy more light and air, and also a comparative degree of quietness. But as to architectural effect of any kind, that must not be looked for, there being no more in the elevations which form such *places* than in the sides of the streets of private houses, which lead into them. Here and there, it is true, there may be a front which possesses greater pretensions than its neighbours: but the same may occur in any other range of houses. Our Squares have an air of opulence and comfort, that is not to be mistaken: but they are quite in architectural undress, certainly not in gala costume,—in superfine broad-cloth, if you will, yet as plain and homely in cut, as if it were drugget. Now we do not say that this is wrong,—on the contrary, we hold such unpretending plainness to be more respectable than tawdry vulgar finery: all we wish is to call things by the right names, and not to talk of "magnificence" where it exists no more than in the garb of a Quaker. Let us leave to such persons as George Robins the humbugging practice of *dignifying* ordinary things by superfine words, unless we choose to be at the trouble of inventing other commendatory epithets to supersede the present hackneyed ones; for at present, those of "magnificent," "grand," "elegant," &c., are so bandied about on every paltry occasion that they have lost all force and meaning, and are in no better repute than the term "respectable." In honest truth, if we look at them with an architectural eye, the character of our Squares is only insipidity. They present neither the charm of piquant variety and contrast, nor that of unity of design. They are nothing more than four ranges of buildings surrounding an open space with a garden in its centre; consequently the *totality* of the design—supposing there to be any design at all—is lost, because the correspondence existing between those separate elevations is hardly distinguishable to the eye. Belgrave Square forms no exception, for even there, owing to the size of the area or *place* itself, the houses—which, by the by, are far from being in the most dignified style, or very best taste—appear low by comparison with it. The elevations produce no collective effect:—the four make no greater architectural impression than a single one of them would do in the same situation; while, on the other hand, if each is considered by itself as a single separate façade, it is very unsatisfactory, because there also we find proportion disregarded, and all grandeur nullified by the multiplicity of small parts.

II. Except what is called the Circus in Piccadilly, and in Oxford-street; and what is called the Polygon in Somer's Town, we have no instances of *places* that are round or polygonal in their plans,—none that are either hexagonal or octagonal, notwithstanding that those forms are well adapted for such purpose in themselves, and would create some variety in our street scenery. Upon a large scale the elliptic shape would be found applicable, and in such case the street might run through it in the direction of its transverse axis. An oval *place* of the exact dimensions of the Flavian Amphitheatre or Colosseum, viz. one whose axes should be 615 and 510 feet respectively, with a garden in the centre, of the size of the arena, would convey a better idea of the vastness of that monument, than Lincoln's Inn Fields do of the Great Pyramid. But to produce its full effect, no such place, be it an ellipse, circus, crescent, or polygon of any kind, should have its circumference broken by being pierced with streets running into it; for it ought to be entered through arches or gateways, over which the elevation should be continued. The Circus in Oxford-street, is no circus at all, but presents merely four segmental slices of one, separated from each other by exceedingly wide streets.

III. It may very fairly be suspected that the new Professor of Architecture at the Royal Academy is not at all likely to gain much credit by the remarks he threw out the other evening, in disparagement of Gothic Architecture. Most assuredly they did not betoken those enlarged and comprehensive views of art which ought to qualify one who fills so important and influential a post, and whose opinions will of course be received with implicit deference by many, and without further questioning or examination. On the contrary they were hardly worthy of a village pedagogue, much less of a Professor of the art. To adopt them, would be to retrograde instead of advancing,—to return to the now exploded prejudices against the Gothic style, which led such writers as Evelyn to condemn it as "a monkish and gloomy" mode of building, wherein no sort of harmony or correctness of proportions is observed! If the Professor be right, all we have been doing for the last forty or fifty years in regard to the study of Gothic architecture, has been worse than useless—positively naught and mischievous, seeing that the sooner we now unlearn it and retrace our steps, the better. It is a pity the Professor was not placed *in cathedra* a few years sooner, for in that case, we should probably have been spared the mortification of seeing the style denounced by him adopted for the new Houses of Parliament. It is further to be regretted that he did not think proper to explain himself by pointing out in detail the defects of the Gothic style *per se*, and what it is that renders it wholly inapplicable—at least unworthy of being applied, at the present day. By not doing so, he has afforded ill-natured people, the opportunity of saying that it was not in his power to support his opinion by aught of argument; consequently, that though it comes from a

---

would have had so many picturesque circumstances in its plan as at present, had its architect been employed to erect an entirely new structure, instead of altering and enlarging the old one. We doubt it; in that case, we should have had such unusual forms and combinations—such piquant *Episodes of Plan*, as the Library formed out of Queen Elizabeth's Gallery, the Waterloo Chamber, and the Breakfast Room at the angle of the two branches of the Grand Corridor.

Professor, it is no more than a bare opinion—a sweeping sentence of bigotted taste, put forth with authority, and seeking rather to silence contradiction than to convince. Fortunately such bigotry is perfectly harmless—likelier by far to excite ridicule, and laughter at the learned Professor's expense, than to prove mischievous by putting us out of conceit with Gothic architecture, and reviving the exploded half-witted prejudices against it. It is odd the Professor should not have seen this, and felt that if he touched upon the subject at all, it became him to do so boldly, that being the only effectual and proper course. At present, it looks as if he was fearful of saying too much,—that is, supposing him capable of vindicating his dogmas of taste. Vague assertion, even though it may proceed from a Professor, is but vague assertion after all; nor would it matter a single straw of itself, were it not that many receive it without further inquiry as an authorative *ipse dixit*, against which there is no appeal:—not however, that such is likely to be the case in the present instance, for we believe that the majority of the Professor's auditors were disposed to contradict him point blank. Mr. Grellier, who fancies "one man's Gothic is quite as good as another's," and one or two others may probably rejoice at finding the taste for Gothic architecture reprobated *ex cathedrâ* at the Royal Academy; but should the matter come to the ears of Mr. Welby Pugin, he will perhaps take up his cudgels again, and flourish them so stoutly as to make the poor Professor cry out "*peccavi.*" Now had the Professor manfully thrown down the gauntlet to Pugin, by formally controverting all that the latter has urged in favour of the Gothic style, it would have been doing something—would have been consistent and to the point. But what avails it to let off a puny little fizgig of a squib against Gothic architecture, instead of battering down the rampart of prejudices by which it is now defended? It is like attempting to knock down a citadel with a popgun.

IV. I frankly confess I do not at all comprehend Mr. Rooke's *sublimities*, nor can I make out what is the standard of Architectural Beauty to which he would refer us. However it is to be hoped that all are not so dull as myself, and will therefore be able to understand and turn to account what seems to have been dictated by the Great Sphynx herself. All that I can gather from his long rigmarole of words is, that Mr. Rooke not only admires, but actually venerates Gothic Architecture, and is therefore not likely to venerate such decriers of it as the present Professor of Architecture, and Mr. Grellier. Let Rooke then take the Professor to task, for it is certain that if he can neither convince nor convert him, he will fairly bamboozle him,—unless the Professor be Œdipus himself.

V. It is to be regretted that we have scarcely any documents at all to assist in studying or forming an acquaintance with the modern architecture of Spain and Portugal. In general, I suspect, it is but in very indifferent taste; nevertheless there must be something worth notice, if only as specimens of the national style. The Spanish and Portuguese architects, however, appear never to have published any of their designs, nor has that task been undertaken for them by foreigners—by any of those artists who have of late years afforded as tasteful studies of Italian and Sicilian architecture. Without going further, there must surely be enough at Madrid alone, to furnish materials for such a work as Gauthier's on Genoa, or Grandjean and Famin's Architecture Toscane.

THE ARCHITECTURE OF LIVERPOOL.

Sir—Having once undertaken to reply to the criticisms of your correspondent Eder on the above subject, I hope, since he has proceeded with his remarks, that you will again favour me with a portion of your space for the continuation of my rejoinder. I wish it may be understood that I pursue this system of counter-criticism from no love of controversy, but with a view to setting the architectural merits of the buildings noticed in their true light, so far as my poor ability may extend. It appears to me that your correspondent often overlooks the leading defects of the buildings he criticises, and expends his severity on their minor, though, perhaps, to the generality of observers, more obvious faults; and on the other hand, sometimes withholds all praise where much is really deserved. In speaking of the Royal Bank Buildings, he exclaims against the extravagant use of ornament in certain parts, but says nothing of its uniform coarseness of design, and utter want of meaning and character. He condemns the height of the basement and balustrade in the street front, but seems not to have observed, and a most singular oversight it is for an architectural student, that the front of the Bank itself facing the court, is composed of a Grecian Doric, and Ionic order, one above the other, and with so ærostyle an amount of intercolumniation, that I could not forbear laughing outright on my first encounter of its mirth-provoking visage; but reflecting that some £30,000 had been expended in producing all this tawdry deformity, I acknowledged to myself that, like Bottom's comedy, this was "very tragical mirth." The Venetian windows on the ground floor of the street front, consist of a little bit of Grecian Doric entablature with two columns and antæ, set on a sill which, with its burden, overhangs the wall beneath it, like that of an ordinary brick house. But enough of this most "original" edifice. Let us follow Eder to the Town Hall. He says it is "highly creditable for the day when it was executed," and in truth, nothing nearly so good has been executed in Liverpool since; it was originally designed by Wood, of Bath, though it has received later additions, (of the past generation,) which have in one or two respects improved it; still the original merit is his. When Eder condemned, with some justice, the carvings between the capitals, which, however, by no means obtrude themselves on the eye so as to become serious blemishes, he might, I think, as a set-off, have noticed the graceful well-conceived figure of Britannia by the late Charles Rossi, R.A., surmounting a cupola, which, though not adhering in its columnar arrangement to the strict rules of Grecian propriety, so often quoted and expatiated on by those who are utterly incapable of making any practical application of their principles, has the merit—and possibly, with deference be it said, the preferable one, in a structure in the Italian mode, and of its moderate dimensions—of a varied, picturesque outline, with perhaps some intricacy of form, but certainly much originality of design. It is, in fact, one of the most pleasing and characteristic features out of many which rear themselves above the ordinary buildings of the town. As regards the Railway station, we shall not materially differ, though I must observe that the capitals of the Corinthian columns are notoriously bad, whether the fault of the design or execution I know not; and that this ugly screen hides one of the best trussed roofs of a large span with which I am acquainted.

I cannot, nor I imagine could most persons, accede to the opinion that St. Luke's Church is a most successful attempt in the Gothic, or rather, the pointed style. The exterior is certainly fine in execution, of an excellent material, and often beautiful in detail; but as a whole, I confess I cannot admire it as some others do. Firstly it wants a clerestory, which gives an appearance of disproportionate height to the tower, and a want of importance and character to the body; and in the next place, the tower itself is far too much of a parallelogram, in which defect I think this church shares with its name-sake of Chelsea, arising, in both cases, from the use of octagonal turrets in lieu of buttresses, of which practice, as applied to a western tower, I have never seen an instance in which the effect was good. I do not extend this opinion to the central towers of cross churches, or Lincoln Cathedral would at once refute me: perhaps the western towers of the same edifice may be quoted against me: but be it remembered, that in this instance a screen wall extends north and south, and gives that air of stability to these towers which they would otherwise want. I must acknowledge they were never entirely satisfactory to me, even as they are. The fine colour of the stone and height of the tower, make this church a fine study for effects of ærial perspective: especially when the pinnacles and turrets of the body and chancel appear in front of the more distant tower, in hazy weather; but while, in this respect, as well as a beautiful specimen of detail, and a fine piece of masonry, I admit the merits of this church to the full, I am of opinion that Mr. Gandy, to whom the design is ascribed, has failed to produce a striking example of the style. The want of a clerestory mars the effect of the interior, and the ceiling of the nave is quite out of character with those of the aisles. A rich wood roof was, it is said, designed for this church, but misdirected economy substituted one of lath and plaster. I can refer Eder to a modern church tower within three miles of Liverpool, which, though on a smaller scale and of an inferior material to this of St. Luke's, is equally good in detail, and in proportion and effect much superior. I allude to that lately added to the parish church of Walton, in which the architect, Mr. Broadbent of this town, has proved that he feels and has imbibed the true spirit of the style in which he worked.

Your correspondent next notices the North and South Wales Bank, in which he says the architect has encountered and overcome "enormous difficulties." Now really I must be permitted to say that I think the difficulties had the best of the battle. The ground is contracted for the accommodation required, and to mend the matter, the architect employs pilasters and columns 3 ft. 6 in. in diameter, and of a proportionate projection, which, with the space required for their bases, must reduce the ground some 2 feet and more in width; and, except the space allowed near the entrance for a most inconvenient winding-stair on one side, and a similar space, but how occupied I know not, on the other, must contract it about 5 feet in length. Again, the building is required to be very lofty in proportion to its extent, and we find an order without an attic employed, although the longest side of the edifice presents nearly a square in elevation, and the shorter about a square and two-thirds in height. Further, the ground is irregular in form; and a pediment being placed over the narrow side, the obtuse angle on the one side, and the acute on the other, become most painfully obvious; while the wall within the columns, being kept at right angles to the long side, and therefore not parallel to its own line of front, quickly calls attention to the irregularity of the plan. The site is about 56 feet by 33, and the interpilastered spaces are two diameters or seven feet; the order, which nearly follows the proportion of the Jupiter Stator example, is raised on a plinth about four feet in height, which latter is pierced for the basement windows; there are three tiers of openings in the height of the order, and the whole exhibits the proportions indicated by the annexed sketches.

Fig. 1.—Front Elevation.

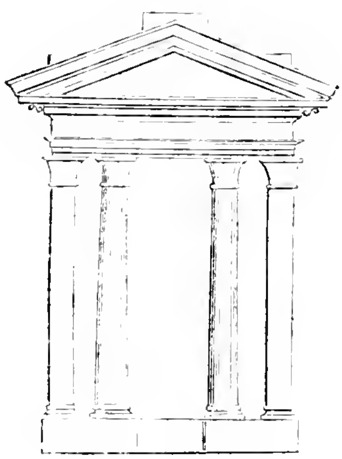

Fig. 2.—Side Elevation.

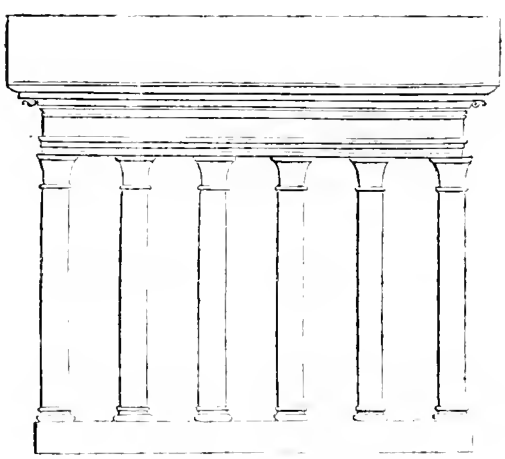

The effect in perspective may be conceived, and I ask whether excellence of detail could atone for such an outrage on architectural propriety and taste as a temple-form structure like this, with three stories in an order. This is an example of the effects of modern competition: where the successful architect, having had his design adopted in consequence, it is said, of his private interest in the committee of management, has not only the advantage, as was understood at the time, of examining those of his competitors, during the six weeks which elapsed between the decision of the committee and the return of the designs to their respective authors, but is permitted to expend about twice the amount to which they were, in the first instance, limited, and this for the purpose of producing a building which is a perfect burlesque on all correct proportion. The execution is creditable to the contractor, but in consequence of having a very poor plaster cast to work from, the capitals are not at all like those of the example professed to be followed. The Union Bank follows its Welsh neighbour in Eder's list. I readily admit the beauty of the Ionic columns, in which a leafy termination has been adopted for the flutes, somewhat in the manner of those in the columns of the monument of Lysicrates. The capitals of the antæ are also original and tasteful, and the bases of both, in which an inverted ovolo is used in place of the upper torus, are improvements on the common attic one; a similar base has been used by Mr. Foulston in the Plymouth theatre. Beyond these details I can discover nothing in this design at all commendable, nor bearing the least trace of the taste which seems to have dictated them. The pediment is filled entirely by the convolutions of an immense motto riband which Eder calls "bold;" would not impudent be a more applicable term? The honeysuckle in the frieze is stiff and ungraceful in the extreme, as are the carvings of foliage and tendrils which occupy part of the panel within the columns. Let any one spend an hour in looking over Stuart's Athens, or Inwood's Erechtheum, and then, walking to this bank, say how much of Grecian character any of these details exhibit. The ponderous truss which stops the cornice at the end next the adjoining building, has a most cast-iron air, as have also the windows of both floors, and the square sham balustrade above them. The lower windows have pediments above a frieze, which is separated from the architrave only by projecting about ¼ of an inch beyond it; while the architrave itself has its moulding sunk on its inner margin, which may occasionally have a good effect in buildings of rustic or unornate character, but seems much at variance with the degree of enrichment which is affected in other parts of this building. The dressings of the small square windows above these I consider equally objectionable, for in them the *fillet* of the architrave alone is broken into knees on every side, while the moulding itself follows the line of the opening. This has a very paltry, poor effect. The pedestals which divide the balustrades into lengths are panelled, and the panels filled with flowers which bear a closer resemblance to tin tartlet moulds with a knob in the middle, than anything else I can think of. The carvings under the portico represent, I suppose, the ladies of the three kingdoms just after the round tea-table has been removed; with a background exhibiting a steam-carriage in full cry along a viaduct which appears to have no end, like the Irishman's rope, beneath which ships are to be seen afloat in something like scale armour. This piece of sculpture forms part of an amusing history. The panel of which it now occupies the centre, was originally filled with foliage and scroll work of similar character to that which now occupies its ends; and the "illustration" of the principle of union was intrusted to two feathered bipeds, who surmounted the pediment, and lugged, each with one foot, at the ends of a cord which encircled what was meant for a bundle of sticks, but bore more resemblance to part of a reeded column. These notable fowls were said to be of the liver or cormorant species; but were much more like, in their proportions and plumage, to the ancient effigy of the supposed fabulous dodo. Short was their reign in their exalted station: the Bank directors not, I suppose, feeling flattered by the constant grins and broad jests of the group of idle corn porters whom the novelty attracted to the opposite corner, and the less obstreperous mirth of the more polished passengers, deposed these eminent sea-birds, and substituted an acroterial honeysuckle closely conforming to the metallic rigidity of character exhibited by its brethren in the frieze, the foliage in the centre of the panel was cut away, the ladies above-mentioned soon made their debût, and no doubt will enjoy a more permanent occupation than their less fortunate predecessors. In closing my remarks on this building, I must observe that, though the stone of which it is built is excellent, and the execution likewise particularly good, the general effect is far from agreeable, there being an angularity and hardness in the details, and a general harshness of outline, which convey an impression of repulsive coldness, and cause an entire want of that attractive lively air which many buildings possess, without at all detracting from that substantiality of expression which should characterize a place of business, and most of all, a Bank. In closing my subject for the present, I can assure Eder, that as regards the Branch Bank of England, I had rather have the credit of designing its street front than the whole of the three joint stock banks he has noticed.

I should have observed, with regard to the Union Bank, that it lays claim to being a complete example of Greek character. I have no hesitation in saying, that beyond the columns and antæ there is not the least ground for such pretensions; but on the contrary, that in common with other buildings affecting Grecian details in this town—with the exception of the pretty little model of the temple of Jupiter Panhellenius, which stands above what was once a most picturesque stone quarry, but has since been spoiled into St. James's Cemetery—it is a glaring example of the inapplicability of that style to ordinary modern uses, showing how completely its unity and simplicity of character are destroyed when more than one height of openings is required, and how impossible it is, by pretending to preserve the details in mouldings, and (save the mark!) in ornament, to overcome the difference of expression which this and other equally wide departures from ancient practice produce in the whole. Moreover, the frequent fractures which mar the entablatures of our Anglo-Grecian buildings should teach us how unfit the common building-stones of this country are for the long bearings and great superincumbent weights which the use of this style imposes on us, but for which the Greek marbles were so eminently adapted. The assumption which some have endeavoured to maintain, that the architects of Greece confined themselves to horizontal composition on account of the superior grandeur of effect which could be so produced, is sufficiently refuted by our own magnificent cathedrals; and I am myself convinced that, had the principle of the arch been known to them, and the almost illimitable power which the architect, by its means, obtains over his materials, none would more fully have availed themselves of its aid than these great masters in science and art. I am aware that I am liable to the charge of reviving truisms; but there are architects who seek to conceal their own dullness under an affectation of enthusiastic admiration of the style of ancient Greece; who abandon and pretend to despise the use of the arch in their designs, because it was unknown to, and consequently unused by, the Greeks, and thus produce buildings which can never be otherwise than unsubstantial and insecure, because constructed of materials unfit for the practice of the style which they affect to follow. I remarked in speaking of the Custom House, that fractures were visible in the stone-work, which I could only attribute to a settlement in the foundations. I have since been confirmed in this opinion, by observing seven or eight similar fractures, particularly in the south and south-western parts of the building, some of a most serious and threatening aspect; thus this extensive and costly pile will, probably ere long, require, like its prototype in London, a repair almost as expensive as its first erection. But to return to the banks. Having disposed of the principal joint stock banking-houses, Eder attacks, without mercy, the building in which the branch business of the Bank of England is conducted. Of the interior of this bank I know but little, and any apparent want of convenience may be perhaps sufficiently accounted for by the fact of its having been originally a private dwelling-house. With respect to the exterior, however, I can assure you and your readers, Mr. Editor, that it is one of the most pleasing street fronts which the town contains. It is of Italian character, exhibiting a Corinthian pilastral order of five intercolumns on a solid basement, with two stories in the height of the order, and an attic above it. The wall between the pilasters and the attic piers, as well as that of the basement is rusticated throughout. The ground floor windows have no other decoration than their moulded cills, and the centre opening, which till very lately was occupied by the door, has the only pediment in the façade, supported on bold trusses. The cills of the one pair windows are lighter and more decorative in character than those of the ground floor, beside being supported by trusses of varied detail and pleasing design, from which festoons of fruit and flowers descend towards the heads of the ground floor openings. The attic is perhaps too high for the order it surmounts, but not more so than is the case in many well known buildings; Greenwich Hospital for example; and the narrowness of the street, and the projection of the cornice almost neutralize this defect. The festoons are well designed and executed, and harmonize with the decorative character of the Corinthian order employed, as does also, in my opinion, the rusticated surface of the intermediate masonry. I do not know the date of this house, nor the name of its designer, but should think it must date some 80 years back; at all events it does credit to his taste, and I am certain that most persons making any pretensions to architectural taste would agree with me that it is much to be preferred before any of the modern banks which have been noticed by Eder. The removal of the door from its proper place in the centre, to the meagre Roman Doric porch beyond the line of front, has injured the unity of the composition, and the subsequent scraping of the stonework has given it all the rawness of a newly finished building, without its sharpness of detail. In closing my remarks on this bank I cannot but express my astonishment at, and pity for, the *taste* which could find so much to admire in the tortured and unnatural decorations of the Union Bank, in the misproportion and coarseness of the Welsh, and consign the Branch Bank to such unqualified reprobation.

The markets next engage the attention of your correspondent. He commends the fish market as well adapted to its purpose, which may be the case now, but certainly was not until the fish-fags rose en masse, and with sundry threats of violence to the architect, demanded and obtained the admission of light in the side walls. St. John's market is capable of fine effects of light certainly, in consequence of its great extent, which on plan is about the same as York Minster, but other merit I cannot discover in it, and the construction of the roof is of the most ordinary and journeyman-like description. In referring to St. James's cemetery I was reminded of the circular structure in which Gibson's beautiful statue of Huskisson is immolated. Independently of the absurdity of setting an eight foot statue in a place not twice that height in diameter, the thing is in itself most ungraceful. I am perhaps forestalling Eder, but he must excuse me. Adopting the details of the Tivoli example of the Corinthian order, the architect appears to have aimed at a mean between the proportions of the temple to which it belongs, and the well known monument of Lysicrates. The result is, that the proportions are neither those of horizontal composition like the temple of Tivoli, nor of vertical, like those of the little monument named. Perhaps habit has given these two ancient examples almost the authority of rule as to the proportions of circular buildings in the classic styles. At all events the medium here attempted is a complete failure, and Bramante's little temple of St. Peter in Montorio, might have given the architect a hint that a varied outline might be preferable to a severe one in so small a building. The terminal which crowns the cupola is far from redeeming the other defects of the design. The enormity of burying so fine a work of art as Gibson's statue in a coop like this, is the more to be regretted, as another by the same eminent sculptor which was intended to occupy the centre of the long room in the Custom-house, has, with the vessel which contained it, gone to the bottom of the sea, somewhere near the mouth of the Tiber. The cemetery in which this (I really scarce know what to call it, for it is neither a mausoleum nor a monument), statue-box stands as one of the lions of Liverpool, and as a matter of course *must* be admired by every body, but really those who do so must prefer seeing animals in a reclaimed rather than a natural state, for it is a very tame lion. I could say more on this subject, but shall refrain for the present; for should Eder, like other "strangers," launch out in admiration thereof, I should prefer giving my opinion in the form of a reply to his.

I am, Sir,
Yours, &c.,
H.

Liverpool,
Jan 22nd, 1841.

ON THE STYLE OF CAMPBELL AS COMPARED WITH THAT OF INIGO JONES.

In pursuing a criticism upon the genius of the Palladian school, the excuse rests chiefly on the influence its pupils have had upon the growth of classic beauty, and on the exertions they have made to rescue the treasures of antiquity from the dust: and though, in looking amidst the ranks of Palladio's followers, we see art for a second time as it were cradled, void alike of vigour or of finish, we cannot but feel pleasure in peeping at its once infant condition, especially as we contrast it with its more advanced state: nor can we feel otherwise than sanguine, as we catch through this in fair perspective its promise of hastening maturity.

Up to the 16th century architecture was less definite in outline, less studied in symmetry;—you were awed by the mass, or were charmed by the intricacy of its parts;—you were arrested, it is true, but then the whole was after all only an agreeable perplexity. It was reserved for Jones and his followers to turn the stream of taste and to transplant the graces of Italy. But the followers of Jones had not very much of their master's sentiment. They seem to have followed the fashion of the time, as much as the sentiment of Palladio. Hence we find Hawkesmore and Vanburgh easily catching the precise feeling of Grecian rule, to the prejudice of the Italian.

Campbell however as a follower of Jones, and as a Palladian architect, seems more deserving of attention, though whether he features the original, or only staggers after him is a question.—In his mansions, (so many of which grace our land) the sentiment of Palladio and the style of Jones seem both affected. Still you are conscious at the first glance of a stiffness in the design. You feel if an importent part is to arrest that it becomes very often unpleasantly independent of the remainder; or if a change of features are successively to please, that you are not led to them by approaches sufficiently easy. The eye is not courted, it is forced.—Sudden changes too often occur from the horizontal to the vertical, in that part where altitude is the aim; and very often in the front a sudden depression of the sides, disuniting to a certain extent the centre from the rest, and destroying in a measure the harmony of relations by a want of unity. It seems as if the artist occasionally lept into his parts; as if notwithstanding his apparent study of every subordinate feature in the Pallatial style, and of the principles of Italian arrangement, the stiffness of the copy must remain, rather than the freedom of the original. It is true that you are looking at the design of a Palladian architect; that there are dispositions of the void and enriched, of the depressed and the elevated; that there are the same segmental and triangular windows in mutual relief; that balustrades crown the void, and that turrets, cupolas, columns, figures, &c. prevent you dwelling on the breadth: but then you see too much of a studied arrangement. You can almost detect the labours of the artist; you can almost discern the process by which the features of his design are apportioned; you see the architect as much as his edifice. When he introduces ornament he makes you to revel very often in a part where the eye should not remain, or he encloses a free figure in some stiff panel and destroys its expression. The decoration is not such that the part would look bare without it, or that the proportion would become affected if it was not there. You see not as in Jones the ornament as identified *with* the mass, but only as a part of it. You detect too much of the hand which placed it there, and too little of its relation to surrounding objects.

Contrasting him with Jones whom he imitates, or with Palladio whom he affects, we at once see that his very study makes him miss the careless beauties of the former, whilst his caution prevents him soaring into the grand simplicity and rich excellence of the latter.

Campbell thus although of the Palladian school is only of such in its leading characteristics. That quick perception of grace and of beauty ever necessary to relieve the huge superficies is not his. His sensibilities seem dull upon the lesser auxiliaries, so useful to design. He is not grand in his comprehension, and yet at the same time minute in his care; or if he does descend to minuteness, he does not change from the greater to the less, from the grand to the inferior with the care of a genius, but creeps into his parts with the fear of a copyist. Finally, he seems to have wanted more quickness of apprehension, more fertility of thought, and more liveliness of fancy, to have in any way equalled his originals.

FREDERICK EAST.

February 10, 1841.

ST. LUKE'S CHURCH, CHEETHAM HILL.

SIR—Being a constant reader of your most valuable Journal, and knowing the great number of communications which must be forwarded to you for perusal, I appreciate the difficulty of the task you have to perform in selecting those which may best serve the two professions, the interests of which you so strenuously and successfully advocate. By way of apology for this communication, the following reasons may be deemed sufficient.

1st. I consider the design and execution of the edifice alluded to to be of such high excellence, that it is only doing a bare act of justice to the architect to whose genius we are indebted for this beautiful work of art, and also to the admirers of modern ecclesiastical architecture, to give a greater publicity to it than it has yet received, and

2ndly. Not having observed anything more than a casual notice of this edifice in your publication, I think a few descriptive remarks, even from an incompetent person, if given in sincerity, and with an eye to the advantage and improvement of the profession, would not be misapplied.

The church under consideration is advantageously situated in the township of Cheetham, on the main road from Manchester to Bury. The funds were raised by subscription, some of the principal residents in the neighbourhood being most liberal in their donations; it is erected from the design of J. W. Atkinson, Esq., architect, who has adopted the Gothic style most happily blending the late ornamental with the early perpendicular style. It is very simple in plan, the body of the church being divided by two rows of piers and arches into nave and aisles; there is a steeple at the west end, and an altar recess at the east, behind which is a large vestry. There are galleries in the aisles and at the west end. The roof of the nave is carried much higher than that of the aisles, so as to admit of clerestory windows.

The steeple consists of a tower and spire. The former has octagon turrets with buttresses at the angles, terminated with crocketted pinnacles. The lower compartment has a well proportioned and deeply recessed doorway, over which is a lofty perpendicular window, and at the sides are windows similar in style. The spandrils over the large window are filled with perpendicular tracery, in the centre of which is the clock. The belfry has two narrow windows on each side, and is crowned with a bold cornice and perforated battlement. The spire is crocketted at the angles, and beautifully connected with the tower by perforated flying buttresses springing from the pinnacles at the angles of the tower; it is finished with a belt and crocketted finial, surmounted by a cross, the emblem of Christianity.

The aisles are divided by buttresses and crocketted pinnacles into six compartments, each decorated with a lofty window: the clerestory has two windows to every one in the aisles, also divided by smaller buttresses and crocketted pinnacles. The nave terminates at the east end with octagon buttresses, and a lofty *side* window to light the altar recess. The east end is simple but original, having *no large east window*, but three well proportioned niches in its place. The ends of the aisles are finished with windows similar to those in the side, and buttresses at the angles.

The whole of the external detail, window dressings, cornices, &c., are good, plain, and effective, and it seems to have been the aim of the architect to obtain a good outline rather than any small frittered ornament, which is only gained at a great expense and trouble, to be lost sight of when viewed at a little distance.

On entering the churchyard from Manchester, the spectator has a S.W. view of the church, the tower standing boldly forward, and the pinnacles and flying buttresses which connect it with the spire giving a diversity of shadow which is most beautiful. The beauty of this view is somewhat lessened by the three large windows in the tower, which crowd it too much, and having only the octagon buttresses at each angle, they seem inadequate to support the weight of the belfry and spire; it is also a pity that the spire was not higher, as it does not harmonize with the beautiful proportion of the tower. At the east end you see the effect of the three niches, which are substituted for the great window.

From the tower you enter a vestibule under the gallery, which is divided from the body of the church by an ornamental glass screen. In the centre of the vestibule and opposite to the entrance door, is a handsome stone font, and on the right and left are doors which communicate with the gallery stairs as well as the body of the church. The altar is beautifully ornamented with perpendicular panels and niches, with richly ornamented canopies; it is lighted by side windows, which have a good effect. It is composed of two compartments, divided by a bold cornice, which runs underneath the side windows. The lower one consists of three Gothic panels with heads of tracery, in which are written the Creed, Commandments, and the Lord's Prayer; on one side of the altar table is a deeply recessed doorway to vestry, and on the other a false one to correspond. The side walls under windows are beautifully ornamented by a series of small arches, springing from isolated columns with foliated caps and bases, forming a sort of triforium. The top compartment consists of a large centre panel, which it is hoped will be fitted with some talented painting; on each side of this are niches and rich canopies; the plainness of the wall above this is hid by perpendicular panelling which reaches to the ceiling.

The pulpit, which is situated rather on one side of the altar, is quite exquisite. The base represents a rock, on which are seated statues of our Saviour and two Magdalens which support the pulpit, it being the medium through which the Gospel is propagated. On the other side of the altar is the reading desk, which is a large Gothic chair, with a stand for the books supported by an eagle; between it and the pulpit is a smaller chair for the clerk.

The organ screen is very beautiful, in the ornamental style, divided into three compartments by niches, canopies, &c., and crowned by three crocketted spires and pinnacles. The organ is a very good one, built by Hill of London, at an expense of about £600.

On entering the church from the west end, the eye is disagreeably affected by the west gallery projecting too far into the church, and cutting short the view of the altar piece; this, however, ceases when you get fairly into the church, and if viewed on a fine day, is very chaste and elegant. Turning round on reaching the altar, you have a view of the organ screen. It is to be regretted that it and the altar piece do not accord better as to style, for there is decidedly a want of unity in them when viewed as part of the same edifice.

I am happy in being able to state that the finishing and painting of this beautiful church was intrusted to the care of Mr. Atkinson, who seems to have spared no pains or trouble in fulfilling the arduous task imposed on him. The whole of the walls are tinted of a warm stone colour, the mouldings left white, and the most prominent members of them gilt, which gives it a most rich and mellow appearance. The ceiling over the nave is divided by the roof principals, and moulded ribs into square compartments, and these again painted in imitation of oak tracery and panels. The pews are painted to imitate grained oak, and lined with crimson moreen. There is accommodation for about fifteen hundred people.

The cost of the church I have not been able to ascertain. The design first determined on was to have been erected for about five thousand pounds, but when it was as forward as the window cills, it was altogether altered, and continued to be so until finished, so that it is now supposed to have cost from fourteen to fifteen thousand pounds.

Craving your indulgence for so lengthened and perhaps unprofessional a description of this interesting and beautiful church, and hoping that you may have an opportunity of testing the truth of my remarks by a personal view of it.

I remain, your obedient servant,

FRANK T. BELLHOUSE, *Architect.*

Grosvenor-square, Manchester,
February 9, 1841.

TABLES ON THE STRENGTH OF BEAMS.

THE formulæ in this Tables are designed to facilitate the computation of the strength and dimensions of Girders, Bressummers, Joists, and other horizontal supports. They are founded on the delicate and important experiments of the late Mr. Thomas Tredgold, combined with the laws of resistance as promulgated by Galileo, and afterwards corrected by Mariotte and Girard. The coefficients are adapted to cast iron of the specific gravity 7·372,* giving a weight of 460¾ lb. to the cubic foot, and they can easily be modified for other materials by simply reducing the tabular constants in the ratio of the specific cohesions, a table of which is subjoined.——NOTE: The results obtained by calculation are all within the limits of elasticity.

l = the length of the beam in feet. m and n = the length of the segments of a beam loaded at some other point than the middle. $m+n=l$ the total length of the beam.

	Rectangular Beams.—Fig. 1.	w = the load in cwts.	b = AB the breadth in inches.	d = AC the depth in inches.	b = A B the breadth, and d = A C the depth in inches.
1	Fixed at one end and loaded at the other . . .	$lw = 1{\cdot}9\,bd^2$	$b = \frac{lw}{1{\cdot}9\,d^2}$	$d = \left(\frac{lw}{1{\cdot}9\,b}\right)^{\frac{1}{2}}$	
2	Fixed at one end and loaded uniformly over the length .	$lw = 3{\cdot}8\,bd^2$	$b = \frac{lw}{3{\cdot}8\,d^2}$	$d = \left(\frac{lw}{3{\cdot}8\,b}\right)^{\frac{1}{2}}$

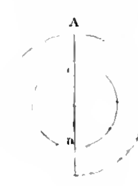
Fig. 8.

Transverse Section.



Specific Cohesion, or Comparative Strength.	
Mulberry	1·492
Oak, American	1·009
British	1·509
Baltic	1·211
Dantzic	0·818
French	1·450
Provence	1·155
Orange	1·761
Pitch Pine	1·284
Plum	1·357
Pomegranate	1·221
Poplar	0·705
Quince	0·841
Tamarisk	1·191
Teak, Java	1·509
Malabar	1·395

The following examples will suffice to show the application of the formulæ:—

Example 1. A cast iron beam of which the transverse section is a rectangle (fig. 1), is supported horizontally on two props placed at the distance of 36 feet apart; what load will the beam sustain at its middle point including the effect produced by its own weight, its depth in the direction of gravity being 22 inches, horizontal breadth 3 inches, and specific gravity 7·372, that of water being unity?

The formula by which this example is resolved, is number 3 of the compartment for the strength of rectangular beams, and by substituting the numerical values of b, d and l, we get

$$w = \frac{7{\cdot}6\, b\, d^2}{l} = \frac{7{\cdot}6 \times 3 \times 22^2}{36} = 306{\cdot}533 \text{ cwts.}$$

If the beam were of Memel Fir of which the specific cohesion is 1·154, that of the given material being 4·334; the strength would be found as follows:—

4·334 : 306·533 : : 1·154 : 81·62 cwt. nearly; and in this way the strength may be calculated for any other material of which the specific cohesion is known.

Example 2. Let the length and depth remain as before, what must be the breadth to sustain the calculated load of 306·533 cwts?

In this case the formula is No. 3 of the values of b, and by substitution, we get

$$b = \frac{l w}{7{\cdot}6 d^2} = \frac{36 \times 306{\cdot}533}{7{\cdot}6 \times 22^2} = 3 \text{ inches.}$$

Example 3. Let the length and the breadth remain, what must be the depth to sustain the calculated load of 306·533 cwts?

Here the formula is No. 3 in the values of d, and by substitution we obtain

$$d = \sqrt{\frac{l w}{7{\cdot}6\, b}} = \sqrt{\frac{36 \times 306{\cdot}533}{7{\cdot}6 \times 3}} = 22 \text{ inches.}$$

And exactly in the same manner may the strength, breadth and depth be calculated for any other case, observing always to employ the constant which is adapted to that particular case.

Example 4. A cast iron beam of which the transverse section is an open rectangle (fig. 2), is supported horizontally on two props 36 feet apart; what load will the beam sustain when equally diffused throughout its length, the breadth being 3 inches, the whole depth 22 inches, the depth of the open part seven-tenths of the whole depth, and the specific gravity 7·372?

The formula for resolving this example is No. 4 of the compartment for open beams, where we have

$$w = \frac{15{\cdot}2\, b\, d^2 (1 - p^3)}{l} = \frac{15{\cdot}2 \times 3 \times 22^2 (1 - {\cdot}7^3)}{36} = \frac{15{\cdot}2 \times 3 \times 484 \times {\cdot}657}{36} = 402{\cdot}7848.$$

The breadth and depth to bear the given load, may respectively be found as in the preceding case.

Example 5. A cast iron beam of the grooved or double flanged section (fig. 3), has its extremities fixed into solid walls which are 36 feet apart; what must be its depth to support a load of 928 cwts. at the middle of its length, the whole breadth being 6 inches, the lesser or middle breadth three-eighths of the whole breadth, and the depth of the middle part or that between the flanges three-fourths of the whole depth?

The formula for this example is No. 5 of the value of d, for the grooved or double flanged section, from which we have, $q = 1 - \frac{3}{8} = \frac{5}{8} = {\cdot}625$, and $p = {\cdot}75$, and therefore it is

$$d = \left(\frac{l w}{11{\cdot}4\, b\, (1 - q p^3)}\right)^{\frac{1}{2}} = \left(\frac{36 \times 928}{11{\cdot}4 \times 6\, (1 - {\cdot}625 \times {\cdot}75^3)}\right)^{\frac{1}{2}} = 25\tfrac{3}{4} \text{ in.}$$

and consequently, the depth between the flanges is $25{\cdot}75 \times {\cdot}75 = 19{\cdot}3125$ or $19\frac{5}{16}$ inches.

Example 6. The whole breadth of a feathered or single flanged beam is 8 inches, the lesser breadth 2 inches, the lesser depth $\frac{5}{8}$ of the whole depth, and the length 36 feet; what must be the whole depth so that it may support a load of 1200 cwts. uniformly distributed over the length, supposing both its ends to be fixed as in the last example?

The formula for this case is No. 6 of the values of d, for the single flanged or feathered section (fig. 4), from which we have $q = \frac{8-2}{8} = {\cdot}75$ and $p = \frac{5}{8} = {\cdot}625$; therefore by substitution we get

$$d = \left\{ \frac{l w\, (\sqrt{1 - q p^3} + \sqrt{1 - q})^2}{91{\cdot}26\, (1 - q p^3 \cdot 1 - q)} \right\}^{\frac{1}{2}} =$$

$$\left\{ \frac{36 \times 1200\, (\sqrt{1 - {\cdot}75 \times {\cdot}625^3} + \sqrt{1 - {\cdot}75})^2}{91{\cdot}26\, (1 - {\cdot}75 \times {\cdot}625^3 \cdot 1 - {\cdot}75)} \right\}^{\frac{1}{2}} = 23{\cdot}903 \text{ inches,}$$

nd consequently the lesser depth is $23{\cdot}903 \times {\cdot}625 = 14{\cdot}94$ inches.

From what has been done above, the mode of reducing the cases for the other sections will become manifest, and since our limits will not permit us to enter at large into the subject, the subsequent illustrations must be left for exercise to the reader.

RAILWAY BILL.

The Board of Trade has opened the campaign against the engineering interests, and we fear with better success than ever. Last year they were defeated on the Steam Navigation Bill, and obtained a partial success on the Railway Act, but by the mere passing of this measure, trivial as it was in itself, they have got the point of the wedge in, and are preparing to drive it home. Fortune has worked well for them in the interim, a series of lamentable accidents continued almost uninterruptedly during the recess, and the government borne on the full tide of public alarm and interested exaggeration, sail on to complete their victory. We attribute their success both last year and this, for we fear that it is already certain, to the inefficient manner in which the opposition was conducted, if indeed that could be called opposition which was to a great degree suicidal assistance. It is true the railway press thundered, but the great division among the railway interests prevented any effective combination, while officious individuals, anxious to show their importance by any kind of meddling, had full opportunity of deluding the ministers as to the feelings of the companies, and of being deluded themselves. We ourselves in this might have been in some degree to blame that we were satisfied with leaving the matter in the hands of the directors, and that we did not enforce that there were other interests also concerned, the representation of which could not fairly be trusted to a body having enough to do to defend themselves. It was a parallel case to the steam navigation bill, and had we done rightly we ought at once to have seen the course which it was our duty to have adopted. We felt that in the one case the steam-boat owners would neglect the interests of the marine engineers, and we aroused that branch of the profession to the necessity of uniting and protecting themselves, co-operating with the steam-boat owners in their opposition to the general principles of the bill, and keeping a watchful eye upon whatever was calculated to affect themselves in particular. A similar course of proceeding it now becomes incumbent upon us to urge in the present instance, the railway directors are absolutely insensible to the dangers which menace themselves, so that it is worse than useless to expect that they will afford any protection to those much more menaced—the engineers. We have seen the disposition to interfere with the due exercise of the profession manifested in the steam navigation bill, and we see it still further developed in the report of the railway commissioners to the Board of Trade. In this report the engineers may find what is in store for them.

With regard to the nature and extent of these powers, the proper distinction appears to us to be that the Government should not attempt to interfere in questions of an experimental nature, which are still subjects of discussion, and admit of a fair difference of opinion among practical men; nor should it attempt to regulate matters of detail, so as to take the management of the railways out of the hands of the parties immediately responsible, viz., the Directors and their officers.

On the other hand, the Government should have the power of enforcing, whenever it is found necessary, the observance of all precautions and regulations which are approved by experince, and are obviously conducive to the public safety. For instance, upon such points as the comparative advantages of six and four-wheeled engines, the best construction and mode of laying down rails, the best form and construction of wheels, axles, &c., and other points of a similar nature, upon which the practice of the best conducted railways differs, and the opinion of the most eminent engineers is by no means decided, it would be premature for the Government to interfere until experience has solved the questions which may still be fairly considered as doubtful.

Here we have an admission that although government do not now interfere, they reserve the right of "doing so at a future period, and they claim the power of introducing upon all railways, whatever has been adopted and proved to be conducive to safety by the practice of those which are considered to be the best conducted." Proved! what has been proved in these days of invention and innovation, has the stage coach been proved? has the sailing vessel? has timber been proved to be the best material for ships? What has been proved to be perfect, or impossible to be superseded? and the Board of Trade would come forward and deprive the engineer of the freedom of competition. Would commissioners, advocates of the fifty-six inch gauge, have allowed the broad gauge and all the consequences attendant on it, or would they have been satisfied with what had been adopted and approved upon the best conducted railways? Would turnpike road commissioners have allowed an approved and adopted mode of communication to be superseded? Let us recollect that invention is already at work to supersede the locomotive, that many of these plans, although not yet brought to bear, have shown great ingenuity, and have been made to work: and is competition to be dependent on the dictum of government commissioners? If the engineers think they will work best in government harness, let them be submissive: if they do not think so, let them at once step forward, and act before it is too late. The railway engineer has had his province invaded often enough by Irish and English railway commissioners to know what he has to expect, so that he ought to want but little urging to impel him to do his duty. The locomotive engineer will see that he has advisers ready to dictate to him the number and form of the wheels of his engines, the axles "and other points of a similar nature," whose thraldom, unless he escape by his own exertions, he will find it difficult to avoid. The marine engineers, and the other branches of the profession have their interests concerned in those of the profession generally, and they must recollect that in fighting this battle they are fighting their own. "Lazarus is not dead, he only sleepeth,"—steam navigation jobs, if they have one head cut off, hydra-like always produce more, and the success of the railway measure will furnish a precedent by which other and more stringent enactments may be obtained. We call therefore on the profession generally to meet, and resist the proposed invasion of their rights—to dismiss all personal disputes on this occasion, and to see only their personal interests—let the younger members of the profession not be behind hand, their career is before them, and if they do not wish their prospects to be blighted, and themselves converted into a set of government sycophants, let them support their elder brethren in maintaining the general cause. We have "nostro consilio" successfully aided in one campaign, we have been rewarded by the thanks of the interest, which we defended, and we pledge also on the issue of the present effort, the same exertions and the same regard for the rights of our constituency.

The chief stipulations which we consider that the profession should make with the government are,

First. That as little interference as possible should take place upon subjects connected with engineering, and that such interference should be limited to matters rendered absolutely imperative by public safety.

Second. That no regulation should be made without the subject in question having been duly investigated, either by the Institute of Civil Engineers, or by a commission composed of engineers belonging to the branch to which the subject relates, not railway commissioners, government engineers, or royal engineers.

Third. That examinations directed by the act shall be public, according to a regulated and uniform plan, and shall be conducted by the Institute of Civil Engineers, or by the departments of Engineering of the Universities of London, Glasgow or Durham.

Fourth. That in case of a difference of opinion between the commissioners and engineers, it shall be left to the decision of arbitrators nominated by each party.

Fifth. That a portion of the railway commission shall be composed of civil engineers.

ENGINE DRIVERS ON RAILWAYS.

The late accidents on railways, and the unfortunate loss of life which has occurred in many cases, have naturally directed public attention more forcibly towards providing some efficient remedy against their recurrence; for although it is very true that the accidents frequent by the former method of conveying the public by coaches were, for the most part, attended by a much greater proportionate loss of life than has occurred on railways, we naturally expect that the talent and expenditure employed in completing these undertakings would have obviated such calamities by foresight and arrangement, and in confirmation of the justice of this opinion, it is further remarkable that accidents, till recently, have been very unfrequent and seldom attended by loss of life. Many railways were opened during the past year, and their want of organization may have tended to cause irregularity. We may also be allowed to entertain an opinion that previous success on older railways has caused, in some degree, a relaxation of care on the part of those entrusted with the management of new ones, both in the selection of proper officers, and in carrying out the recommendations of those professionally engaged in the practical detail, so as to effect that uniformity of action throughout the entire establishment which is necessary to insure success. In the management of a railway, as in that of the army, it appears necessary that business should be conducted by a head manager, deriving his authority and receiving instructions immediately from the board of directors, having under him gradations of officers, who should be held responsible for the due performance of the duties of themselves and their subordinates, and have the power of appeal to the board of directors in cases of dispute, they should also be protected from the individual interference of receiving orders from any other than their superior officer in each department respectively, and these superior officers from the manager as the official organ of the directors.

It may be argued by many, that such an arrangement as we propose would open a door to abuse of power by the superior officers and manager, but a determination on the part of the directors to maintain order and gentlemanly feeling among them, by considering with impartiality and minuteness every case of appeal brought under their notice, and by reprimanding the delinquent, however high his station, would effectually curb any such evil.

Most, if not all, railway companies have established some code of regulations for a portion, at least, of their servants but recent inquiries seem to show that they have not always been enforced with the decision necessary to render them available in all cases, and it is doubtful how far they may embrace and define the duties of every servant connected with the executive, for unless their respective responsibilities are clearly understood, it will become difficult to ascertain which of two parties may have acted improperly, although each be actuated by a laudable desire to further the safety of the public and the prosperity of the railway; the decision on the part of the directors becomes doubtful, and perhaps the occasion may pass without being legislated upon at all, or at most an order is passed which, being observed for a time, falls into disuse from its isolated character; and if it becomes necessary to adopt any improved local arrangement, this is also in danger of being applied to individual cases rather than to the general system.

The responsible duties of the engine-driver conducting each railway train, have marked him out as the peculiar object of public inquiry and censure, and it may be naturally assumed as unfortunate that these men have risen in many cases from classes uneducated, so far as book learning is concerned. The knowledge of reading and writing, no doubt, gives man a moral standing and feeling of confidence that can be acquired in no other way, but we by no means admit that engine drivers are uneducated for the duties required of them, after having undergone a practical apprenticeship for many years as assistants on the engines they emulate to conduct and being intrusted with their care after proving themselves sober and attentive servants.

Men educated in the theoretical knowledge of the laws of latent heat and expansion of fluids, would, we think, be quite unable to conduct an engine ten miles without an accident, unless they were practically initiated in its management by serving an apprenticeship to the more menial duties; and it is very doubtful how far he would exercise the continued watchfulness and caution necessary, if the sense of danger were removed by too much confidence in the efficiency of an education such as has been proposed by sending them to institutions for acquiring this knowledge.

Of the many accidents which have lately occurred on railways, we think that there has been a prevalent want of system in giving signals, as well as disregard of duty in not exhibiting them. To render signals efficient, they should be conducted with the *greatest simplicity* as well as certainty, and where many signs are sought to be conveyed, as proposed by the Railway Conference, there is great danger of an improper one being used. Where a signal of danger becomes necessary, it must generally occur from irregularity or accident, and we think the railway system will not be complete until provided with a ready means of immediately transmitting information to every part of the line, as by telegraph. This has been adopted on a short line in the metropolis on the electro-magnetic principle with eminent success: indeed we doubt if the business could be conducted with safety unless provided with such an instrument; an efficient means of communication is also required between the guards and engineer of the train, to give information of any accident that may occur to a carriage or otherwise.

Engine drivers are, however, placed in so important a relation to the safety and proper conduct of railway trains, that it has become a serious necessity, felt alike by the proprietors of railways and the public, that they should become or be chosen from a superior class of operatives, and it is their position to which we wish to call more immediate attention. To attain this object it is indispensably requisite that their moral conduct and emulation in the skilful discharge of their duties should be fostered by the due consideration of their superior officers and employers, and that they should be carefully protected from interference or injustice when acting with propriety. As a reward for merit we should recommend an honorary, rather than a pecuniary consideration. A medal, we think, would prove a more certain inducement, from its being, *after years*, a certificate of good character.

By law, engine drivers of railway trains have not hitherto been contemplated as a distinct body, nor have their duties and responsibilities been defined, except in general acts relating to all servants of railway companies, and it is to this point we think the attention of legislature may be directed with peculiar advantage; in case of accident occurring from negligence, it is of vital importance to the community at large that at any rate the delinquent should not again be suffered to risk the loss of life, the mere punishment by fine or otherwise is not enough to protect the public, and no combination of the railway interest to denounce the man as unfit for the trust is sufficient to meet the case, for unless the delinquent has been condemned by an impartial judge, fully competent to understand the case, it remains uncertain if he or some other have been guilty of the offence, and opens a door to persecution which will effectually prevent men of honourable intentions from accepting duties of so arduous a nature; it is therefore as necessary that they should be protected from injury when discharging their duties with fidelity and care, as that they should be punished when the reverse obtains, and to attain this object we should propose that men in this occupation be governed by laws in some measure similar to those enacted for the observance of pilots, to whose duties as conductors and guardians of life and property they approximate more nearly than to any other.

For this purpose it will be necessary to institute a corporation similar to that of the Trinity House, whose duty and responsibility it should be to examine and grant licences to proper persons for the conduct of railway engines, and to make bye laws for their regulation, and enforce them after approval of the Privy Council, which bye laws should be publicly exhibited for the inspection of all persons interested therein, for at least three months previous to being enforced. In carrying out the intentions of a new act of this description, it would be necessary to allow some latitude in the granting of licences to those who are at present engaged as engine drivers. In future, however, those entrusted with the charge of engines might be divided into three classes, viz., 1st, engine drivers; 2nd, engine drivers or stokers; and 3rd, apprentices; the two former should always accompany the engine, and perhaps the apprentice also, whose instruction should, however, in part consist of mechanical knowledge acquired in the workshops; as fitter each man should derive his authority to act in either capacity by licence, stating the grade to which he belonged, granted after due examination and certificate on oath of the examining officer, which licence should be renewed every year. Each apprentice should serve five years before he becomes eligible to receive a licence as second engine driver, and each second engine driver should farther serve three years before he is entrusted with the entire command of an engine as first engine-man, when he should execute a bond for securing obedience to the bye-laws. An annual premium should be paid for each licence, to defray the expenses of carrying out the act, and the surplus be carried to a fund for superannuated and infirm drivers, which fund should be also provided for by a per centage of (say) sixpence per pound retained from their earnings when employed. All appointments should be registered. Licences should be revoked, annulled, or suspended by the engineer-in-chief, and those suspended may appeal to the corporation.

No unlicensed person should take charge of any engine, under a penalty. The description should appear on his licence, and none be allowed to act until registered, or without producing his licence. He should deliver up his licence when required, and be liable to penalty for acting when suspended. He should be liable for lending his licence, for drunkenness or misconduct. Drivers quitting without consent should be liable to penalty, and a penalty should be enforced on railway companies for employing unlicenced engine drivers. Penalties should be appropriated to a relief fund. It would not, however, be a sufficient security to the public that the engine drivers only be made subject to these or similar regulations, it is imperative that all other servants connected with the transmission of trains should be subjected to similar regulations and strict definition of respective duties.

We think it has been far too frequently the practice to allow blame to be cast on the engine drivers, rather than sift to the bottom who may have been the real delinquent, and it has been lost sight of by the public, that perhaps eight out of ten of the late disastrous accidents are not wholly attributable to their negligence, and that such a groundless charge against a body of men when endeavouring to exert their utmost abilities, is calculated to cause a bad moral influence, and debar intelligent persons from accepting a situation where no protection is afforded.

DRAINAGE BILL.

We have long wished that some measure should be brought forward to provide an efficient system of architectural police, and we are pleased to see at last some hopes of this being effected. In the hands of the architect and the engineer to a great degree are left the health and happiness of the population, and this is particularly the case in large towns. The medical man does but follow, for the responsibility lies more on the architect than on any one else. Most of the requisites for health depend on the due administration of his duties, food is supplied by others, but he has to provide lodging, water, drainage—nay, it may be said, even air. If we want to appreciate how great is this responsibility, let us take two cases from this metropolis, we will take the western or Kensington division, and the eastern or Whitechapel division, in the former the annual average of deaths is 2·2 per cent., in in the latter 3·4 or more than 50 per cent. higher, a result attributable mainly to the want of drainage and to the bad mode of construction. In Whitechapel there are as many as four females in a hundred who die in a year, an average as low as that of Lisbon, while as we have seen, in another part of the metropolis the average is little more than one half. It is not our purpose at present to enter at any length into this subject, for we presume that our readers must be too well aware by experience of the main facts—we here however state it as our decided conviction that one-third of the deaths in this metropolis, causing an annual loss of TEN THOUSAND LIVES, is mainly owing to the inefficiency of our architectural police, and let it be remembered that London is one of the healthiest cities in the world, that even the great partial mortality of which we have spoken is nothing to that of Dublin, Manchester, Glasgow or Birmingham—still in the last ten years One Hundred Thousand Lives have been sacrificed in this metropolis of civilization through the ignorance of the public, and the negligence of the legislature.

Upon the architect, we have explained, that there devolves a high share of responsibility, that upon the due discharge of his duties the health of his fellow-citizens is dependent, we therefore say that it is incumbent on the profession not to be supine under such circumstances, but to give every aid in their power towards remedying the evils which have sprung from a bad system. The proper fulfilment of these onerous duties gives the architect a high claim upon the public sympathy, and must tend to raise the moral and social position of the profession. The architect ceases to be an artist, whom we call in to minister to our luxuries, or a mechanic, whose brick and mortar services we can cheaply pay, he comes before us in another capacity, he has more weighty cares, and the public will not only give him a larger share of their esteem, but a greater measure of power. It is to instructed men that the public have to look for the efficient direction of a proper system, and to no other hands can it be satisfactorily confided. We therefore call on the profession in the consideration of this important question to dismiss their private interests, and to consult only their public obligations, to look with kindness at measures calculated to elevate the dignity of their pursuits, and to see defects only for the purpose of giving every assistance to amend them.

We confess that the consideration of recommendations, such as those contained in the Drainage Bill, is to a certain extent involved in difficulty, for an interference with existing modes is evidently calculated to disturb and seriously injure many private interests. By the proposed enactment the landed proprietor will not be allowed to build as he likes, he will be put to expenses which he would be anxious to avoid, and he will not be able to make as much as he formerly could of his property. This is the first feeling suggested on reading the bill, but we should take but a narrow view of the question did we limit ourselves to such a view. There are other private interests concerned besides those of the holder of building ground, there are the interests of all classes of the community which are affected by the bad working of the present system. Let us suppose that in the midst of Pimlico or the Regent's Park, among houses in which every comfort has been studied, a small plot should be left unbuilt, it is clearly in the power of the owner at present from the demand for habitations created by the population already established in the neighbourhood—it is clearly in the power of the owner, we say, to establish a pernicious fever colony in the midst of the most healthy district. In his anxiety to make the most of his property he may, as others have done, build a nest of houses, back to back, with narrow alleys, no thoroughfare, and without drainage, and without provision for the removal of filth of any kind, or he may do worse by letting all the refuse fill one open drain. Let the windows be small and immoveable, the rooms of the most cramped dimension, let him fill these houses with those who are unfortunately competitors for the worst accommodation, and malaria will do the rest—fever will spring up in the devoted district, the houses of the poor will be desolated, death will do his work in every house, ten, twenty, thirty cases of disease in one habitation—the leaven has worked, and pestilence will go abroad to carry its warfare among the rich and the beautiful, and teach its awful lesson of the common interests and common liabilities of human nature. This is no exaggerated picture, no effort of the imagination, we can point out the districts, name the houses, number the victims,—a fever map of the metropolis would be dotted with black and livid colonies of death—here is the active volcanoe, here is that which has had its day of ravage and now slumbers for awhile—in that darkened alley, where there is scarcely a pathway for the solitary visitor, sixty cases of fever have broken out at once—that row of lodging houses forms one perpetual hospital, the surgeon is never absent from its doors, the hearse is a punctual visitor. All the evils, which we have depicted, may be brought about by ignorance or negligence, and there is no remedy, except at the expense of the victims. The sewers are made from the general rates, the union officer is sent to cure the sick, the weakened labourer, the widow and the orphan become burthens on the poor rates, the public slumber, another crop is prepared for the scythe, the same scene is repeated, and still we remain inactive. It would be no exaggeration to say that the portion of poor rates in Marylebone immediately attributable to fever colonies is not less than twenty per cent., a heavy penalty for private cupidity and public negligence. It is therefore no valid interest for which the landowner would ask protection, he has profited by a public wrong, and on the remedy of that evil he must abide the consequences, were they more severe then they are likely to be, while he will equally profit by the public advantage. The results to be expected from an efficient system of architectural hygiene are a diminished rate of mortality among all classes, and a considerable reduction in the poor rates —advantages, we presume, in the contemplation of which all private interests must sink in the scale. The amount of poor rates for the metropolis alone is above half a million, a sum the diminution of which cannot fail to be a boon, while it will furnish a good set-off against any expenditure which may be necessary under the new arrangements. In the profession, as regards personal interests, the same compensation will be the result, if any loss should be sustained by the builders of low class houses, yet there is again in the increased activity given to other departments.

Taking up the bill itself, under these circumstances, and considering that it has yet to pass through committee, we shall bear but slightly upon its individual details, for although many of them are highly objectionable, yet as a general feeling prevails that they will be amended in the further progress of the measure, it would be but wasting the time of our readers. The first clause by including every borough and market town, necessarily takes in many places of small population, in which the proposed enactment would be unnecessary, we should therefore suggest, that there should be a general limitation, to the wording of the clause any borough, market town, town or village, having more than —— thousand inhabitants. We certainly think that it is but equitable that those proposing to build on any property should provide it with proper sewers; streets are as much for the public as for private use, but sewers are more for private use than for that of the public. The second clause, which is retrospective, and requires drains to be made for unprovided houses now existing, we think bears particularly hard upon the occupier, and we hope will receive due modification. The third clause provides for the alteration of foundations on rebuilding old houses, and though it will prove burthensome, is a necessary consequence of the general tenour of the bill. The seventh clause gives a usual and necessary power to commissioners of sewers to open any private drain, and the eighth, power of compulsory cleansing of drains, water-courses and cesspools. The seventeenth clause provides for the inspection of all proposed buildings by the surveyor, who is to see that the provisions of the act are complied with, fixing a maximum fee of 3*l.* 10s., and a minimum of 15s. The nineteenth section enacts that houses are not to be built below the level of the ground without areas. The 20th clause declares that no close court shall be built nor any of less width than 20 feet; the Marquis of Northampton who has already alluded to the subject, will probably move as an amendment that the width of alleys and streets be regulated by the height of the houses. By the succeeding clause houses may not be built back to back. The 23rd section says that walls shall be founded on concrete; the 24th that the level of the ground floor shall be at least 18 inches above the level of the footway or road adjoining, and air bricks shall be built in the walls 9 inches below the level of the floor, so as to allow of the free circulation of air beneath. The 25th section is the one, which has excited the most attention; it provides that no room in any house having only one room on the ground floor, or having only four rooms in all shall be less than eight feet in height, and that in every such house there shall be at least one room 12 feet by 12 in the clear. The next section provides that every room containing 144 square feet of flooring shall have at least one window of specified size, which admits of being opened freely. The restriction as to height and breadth appears to be bad, as the object might be answered effectually by requiring a superficies for windows of 14 square feet and a quarter. The 27th clause declares that cellars shall not be occupied as dwellings, but it seems very difficult at present to carry such a provision into effect, for in Liverpool there are 35,000 persons living in cellars, and in Manchester 15,000, a population which it would be inconvenient suddenly to dislodge.

By next month the bill will have assumed a more tangible form, and we shall then be enabled to consider in what way the clauses will bear on the profession, but at present, with the prospect of extensive modifications, we feel that this labour would be useless.

THE HALICARNASSIAN MARBLES.

THE attention of the learned world has lately been much attracted to the precious remains of ancient art still existing in Asia Minor. The researches of the Dilettanti Society had contributed not a little towards a knowledge of some of its architectural monuments: and the labours of Captain Beaufort had opened the means of acquaintance with the southern coast. But it was not until the publication of the travels of Mr. Fellows, in 1839, that the public became aware of the extent of the treasures that exist in that most important part of the ancient world. In consequence of the interest excited by his work, Mr. Fellows was induced to return to that country, under the auspices of the Geographical Society; and we are informed that the result of his journey has been the acquisition for the British Museum of some sculptures of a most valuable character, from Lycia; and the construction of a correct map of a portion of classic ground which Lieutenant-Colonel Leake describes as "a complete blank." So little was known of the interior of Asia Minor, that it was left for Mr. Fellows to make the discovery of various cities of great extent, with whose very names no previous acquaintance had existed, among which one may be particularized numbering a population of not fewer than 30,000 souls. We trust that the result of these researches will soon be brought before the public. In the mean while it is our present purpose to solicit attention to the fact of the existence of some highly valuable remains of antiquity at Halicarnassus, the ancient and celebrated capital of Carya, in order that advantage may be taken of our present favourable position with regard to Turkey, and that, while our fleet is in the immediate neighbourhood, the sculptures in question may be rescued from the ignorance and barbarism of their present possessors.

Halicarnassus was situate on the coast of Asia Minor, near its south-western extremity; and, upon the death of Mausolus, the King of Carya, B.C. 330, it became remarkable as the site of that famous monument erected to his memory by his Queen Artemisia, which gave the name of Mausoleum to all similar structures, and which is so elaborately described by Pliny. The present name of this place is Boudroun, and it forms a part of the province of Anatolia or Anaboudl. Boudroun appears to be, through the term Petrumi, as the Turks write it, a corruption of Pietro, or "Castellum Sancti Petri." The best account of this spot and its antiquities, with which we have been able to meet, is that contained in *Dr. Clarke's Travels*, vol. iii., pp. 256 and 268. In a note on the latter page, he says, "We are indebted for the information which follows, concerning Halicarnassus and Cnidus, together with the plan which accompanies it, to the observations of Mr. Morritt, celebrated for his controversy with Mr. Bryant on the subject of Homer's Poems and the existence of Troy. It is the more valuable, because few modern writers have visited these ruins; and certainly no one better qualified for the undertaking :—

"June 14, 1795.—We set out in a boat from Cos, and in a few hours reached Boudroun, the ancient Halicarnassus, a distance of 18 computed Turkish miles. This small town stands on a shallow bay, at the eastern extremity of the large and deep port of the ancient city. Off this bay lies the island mentioned in Strabo by the name of Arconnesos, Αρκοννησος. (Lib. xiv., p. 656.)

"June 15.—We tried to procure permission from the disdar, the Turkish governor of the castle, to see the interior of that fortress; but after a long negotiation we were at last only permitted to walk with a janissary round the open ramparts, his jealousy not permitting the inner gates to be opened into the court. The castle is a work of modern date, but built in a great degree of ancient materials, confusedly put together in the walls. There is a plate which gives a correct notion of its general appearance in the *Voyage Pittoresque*. We found over the door an ill-carved lion, and a mutilated bust of ancient work. Old coats of arms, the remains probably of the Crusaders and the knights of St. John of Rhodes, are mixed in the walls with many precious fragments of the finest periods of Grecian art. There are several pieces of an ancient frieze, representing the combats of Theseus and the Amazons, of which the design and execution are equal to those which Lord Elgin brought over from the Parthenon. These are stuck in the wall, some of them reversed, some edgewise, and some which have probably been better preserved by having the carved side towards the wall, and inserted in it. No entreaties nor bribes could procure these at the time we were abroad; but now, if they could be procured, they would form, I think, a most valuable supplement to the monuments already brought hither from Athens. From my recollection of them, I should say they were of a higher finish, rather better preserved, and the design of a date somewhat subsequent to those of Phidias, the proportions less massive, and the forms of a softer, more flowing, and less severe character. It is probable that these beautiful marbles were taken from the celebrated Mausoleum; of this, however, no other remains are discoverable in those parts of the town we were permitted to examine. I found an inscription this day, near a fountain in the town, containing hexameter and pentameter lines, on the consecration or dedication of some person to Apollo."

In allusion to the same subject, Captain Beaufort has remarked, "Numerous pieces of exquisite sculpture are inserted in the walls, representing funeral processions, and combats between clothed and naked figures."

The Bay of Marmorice, where our squadron is now wintering, is in the immediate neighbourhood of Boudroun; and the facilities arising from this circumstance have produced much anxiety that the attention of the Government should be called to the facts thus briefly adverted to. In compliance with a memorial on the subject from the Architectural Society, Lord Palmerston recently granted the honour of an interview to a deputation from that body, at which the president, Mr. W. Tite, and the secretary, Mr. Grellier, laid before his Lordship a statement of all the authorities they had collected upon the existence and present condition of the remains under consideration. His Lordship promised that he would write to Lord Ponsonby and Admiral Stopford on the subject; and we have only to express our hope that his negotiation may terminate in the acquisition of these sculptures for our national museum, where they will form a noble link in the chain of Grecian art, and compensate in some measure for the loss of the Phigalean and other marbles.—*Times*.

[In addition to the foregoing extract from the *Times*, it will be seen by the correspondence which we have subjoined, that the Institute has not been behindhand in taking up this subject. We are gratified with the prospects which arise from Lord Palmerston's active and kind interference.]

Copy of a Letter from the Royal Institute of British Architects to Lord Palmerston.

My Lord—The Institute of British Architects, having become acquainted, through some of its members who have visited Boudroun, the ancient Halicarnassus, that there are several fine specimens of Grecian sculpture inserted in the walls of the Castle without any regard to the danger they incur in such a situation, are induced to submit to your Lordship that it is most desirable to take advantage of the present favourable epoch for obtaining, if possible, the accession of these valuable relics of antiquity to our national collection, for their rescue from the degradation and destruction to which they are now exposed, and for the advancement of British art. In addition to the feeling which the members of the Institute entertain in common with others connected with the fine arts on the subject of these marbles, they attach the greater interest to their acquisition from the circumstance that they originally formed the decorations of a celebrated structure of ancient Greece.

The Council of the Institute further presume most respectfully to suggest to your lordship, that in the event of Her Majesty's government applying to the Sublime Porte for these sculptures, it would be desirable, at the same time, to request an authority to search for, and remove other remains of ancient art on that site and others on the coast of the Levant, where numerous valuable relics are well known to exist; and should this suggestion be entertained, the Institute, through its members who have visited the localities in question, will have much pleasure in contributing every information and assistance in their power to promote an object so important.

We have the honour to be,
Your Lordship's most obedient and humble servants,

C. Fowler, }
A. Poynter, } *Hon. Secs.*

The Lord Palmerston.

(Reply.)

Foreign Office, Feb. 9, 1841.

Gentlemen—I am directed by Viscount Palmerston to acquaint you for the information of the Members of the "Royal Institute of British Architects" that in compliance with the request contained in your letter of the 29th ultimo, his Lordship has instructed her Majesty's Ambassador at Constantinople to endeavour to obtain the permission of the Porte, for the removal of the ancient sculptures at Boudroun, mentioned in your letter, and also for the removal of the other marbles in the neighbouring districts alluded to in your letter.

I am, Gentlemen,
Your most obedient humble servant,
J. Backhouse.

C. Fowler, Esq., and A. Poynter, Esq.

THE COMMERCIAL DOCKS AT SOUTHAMPTON.

This central port, considered in its adjacency to the ocean, is at the same time, the most convenient for commerce. It has the Isle of Wight for a breakwater, with entrances on the west, by the Needles—on the south, by Spithead and the Mother Bank, with the Waters of the Solent for a sheltured outer anchorage. The harbour itself is most admirably fitted for the accommodation of trade, being ten miles in length, four miles above, and six miles below Southampton, with a wide and abundantly deep channel and the best anchorage. Nature has likewise provided a situation peculiarly fitted for commercial docks, at the very foot of the town of Southampton, and immediately contiguous to the South Western Railway, the connecting link between this noble harbour and the river Thames: the site of the docks, 208 acres in extent, is accessible on three sides, by the river Itchen and Southampton water—the most protected side being the margin of the Itchen—where the water is 12 feet, low water spring tides, and which is being dredged to the depth of 18 feet.

One of the docks now in progress, is intended to be opened at the expiration of six months or thereabouts, which will contain 16 acres of water, of the depth of 18 feet, low water spring tides, open at all times of tide, with an entrance of 150 feet in width, avoiding the expense of constructing and working entrance locks, and preventing any occasion of delay in entering or departing. To these important considerations, never before combined in any similar enterprize, is to be added, that the wharf ground, between the northern frontage of the two docks to be first constructed and the town, is of a description so ample as to admit of goods being lodged or housed in large quantities, under sheds and in warehouses, having vaults and a ground floor only, or of being otherwise so constructed as to require bnt little cranage.

The inducements to resort to these docks may be thus explained—first, as to the merchant of Liverpool,—second, as to the merchant of London.

1. As to the merchant of Liverpool.

It is well known that a given value in exports from Lancashire is comprehended in much less bulk than the same value invested in the produce of the countries to which the outward cargoes are exported, and that the colonial or other produce imported in return, is of much greater amount than is required for the market of Liverpool. The surplus is, in part, now consigned to London, but it must be obvious that provided as good a market can be found at Southampton, the merchant of Liverpool will prefer that port to London, for the following reasons.

1. The more early arrival of the vessel at its destination.

2. The smaller expenses of the port, in pilotage, light duties and other charges.

3. The nearer proximity of Liverpool, should the vessel be required to load outwards at that port; or if not, the shorter voyage to its ultimate destination, if down channel.

These reasons may be considered as conclusive, provided there be an equally good market for the inward cargo.

With reference to that question, it may be stated, that two millions and upwards of people are now supplied with grocery, fruits both green and dry, and other imports, first carried past the Port of Southampton, to encounter the delays, and be incumbered with the expenses of the navigation to and at the Port of London—which delay and expenses are doubled in conveying back these goods to the ports of the English channel, between Newhaven and Falmouth. Thus are two millions and upwards of the inhabitants of England now supplied with articles of import, instead of this merchandize being landed at Southampton, to be distributed with the greatest facility, weather permitting, to the Isle of Wight, and the numerous ports on the channel, Newhaven, Chichester, Portsmouth, Lymington, Poole, Weymouth, Bridport, Lyme, Dartmouth, Exeter, Teignmouth, Plymouth and Falmouth. That the merchant of Liverpool will be most anxious to profit by this opportunity of sharing, more largely, at an easy expense, in the supply of the markets of the south-west of England, cannot be doubted, and that he will therefore freely use the port of Southampton, may be considered as certain.

2. As to the merchant of London.

He has also to consider how to deliver goods to the consumer with the greatest despatch and encumbered with the least expense. Even supposing him to determine not to deviate from the old and beaten tracks of business, the effect must be, the abandonment of the markets of the South West, to the activity and enterprize of the merchant in the North West of England. Such a case, however, will not arise, nor will the merchants of London be slow, although some may be unwilling, to avail themselves of the means of despatch, economy and other advantages attendant on the adoption of Southampton as a branch port.

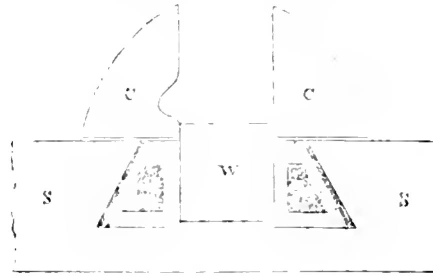
Nor are the inducements to prefer the Port of Southampton confined to the home trade. The large quantities of merchandize now brought to the Port of London to be re-shipped for colonial and foreign markets, will find a cheaper and more convenient depôt at Southampton, and especially the extensive class of imports from Java, the Brazils, Havannah and other foreign states or possessions, destined for foreign consumption, will, as matter of course, be carried to that port which can be the soonest reached, is the least expensive and the best situate for general distribution to the consumer, and such will be the Port of Southampton, being, at the same time, not less adapted for the collection of the outward cargo, now brought into the Port of London to be carried out again at a heavy expense.

The dock intended to be opened in September next, is to contain, as already mentioned, 16 acres. The second dock, also in progress, which is to be a close dock, will contain 14 acres of water—the whole of the enclosure of land and water, for these two docks, will comprehend about 60 acres, affording an extent of accommodation capable of yielding, if fully employed, at the rates charged by the docks of London, a nett income of £150,000 per annum, upon an outlay of £500,000 or thereabouts, of which it is proposed, agreeably to the provisions of the Act incorporating the Company, to borrow £150,000. There would then remain to be enclosed 140 acres more of the dock land. It would be premature to indicate by more than a slight sketch the probable occupation of that part of the site. It may, however, be shown, that there are easy, cheap and profitable means of using this ground so soon as sufficient trade shall have been attracted to Southampton to justify an extension of the works already undertaken. About 90 acres of the 140, running south of the present works would furnish ample accommodation for a trade in timber and coals—by being divided into two parts—a dock for timber ships and colliers, and an enclosure for timber ponds, where timber both afloat and in stack, might be bonded to a great extent. The then remaining part of the dock land would be about 50 acres, on the western side, bounded by Southampton water, a situation admirably calculated for a second close dock, should it ever be required. The works of the first or tide dock are far advanced,—it is intended to be opened to the merchant and shipowner in the month of September next; the second or close dock will require another year.

The Royal Mail Steam Packet Company is under engagement to work to and from this dock. The extensive trade now conveyed by the Peninsular Steam Packets has already located itself at Southampton, several ships run to the Mauritius from this Port for sugar, and it is well known that large commercial capitals both of London and Liverpool employed in the East and West India trades are awaiting the accommodation of these docks, in order to avail themselves at the earliest moment, of the advantages of supplying the large and flourishing population of the South West of England on terms with which it will be impossible to compete, by subjecting merchandize (in bringing it to London) to an average delay not to be estimated at less than one month (including the two passages), and at the same time to the heavy and oppressive expenses of the Port of London, and of its export from that Port, for distribution for domestic and foreign consumption.

Ice-cutting Steam-boats.—Letters from Copenhagen of the 18th ult. state, that M. C. M. Hjorth has just resolved a problem which, for upwards of ten years, has vainly exercised the sagacity of naval engineers—and whose solution has more than once been proposed for competition, as well by the General Administration of Posts, as by the corporation of merchants in the capital. He has invented a steam-boat capable of cutting its way through the thickest ice, with a speed nearly equal to that of its unimpeded navigation. The General Administration of Posts have received a most favourable report from a committee of ship-builders and machine-makers, to whom they had submitted the model, and have applied for authority to construct a vessel for the transport of the mail during winter.

HARPER'S PATENT RAILWAY CHAIRS.



Perspective view of improved chair.
C C. Cheeks of chair; W. Oak wedge upon which the rail rests; S S. Sleeper.

The annexed engravings represent the patent chair which has been introduced on one hundred yards of the South Western Railway, about half a mile below the Winchester station, in November 1839, since then the down trains have regularly passed over them.

The resident engineer, Edward Dixon, Esq., has favourably reported upon them several times down to the 28th of December 1840, the following are extracts from his reports.

"The principle is good in doing away with the use of spikes, and the enormous injury arising from the splitting of sleepers by boring and spiking. I have not paid sufficient attention to speak decidedly as to the difference of noise, but the result should certainly be favourable."

"I should like to see it laid on a large scale, as it has several advantages over the present method."

"I do not think any of the chairs laid down broke in the fixing, and none have broken since, I consider them less liable to breakage than the old chairs, there being no spikes to drive in, the risk is reduced, and in keeping the rail after the chair is fixed, there would be less chance of breakage from a miss-blow of the keying hammer striking the cheek of the chairs, on account of the wood which holds the chair in its place allowing of a little elasticity."

The Directors of the above Company have assented to an application made by Mr. Harper, and the engineer-in-chief Joseph Locke, Esq., has fixed for a further trial to be made on the Gosport Branch, near Winchester.

The saving of expense is stated by the patentee to be nearly 300*l.* a mile, exclusive of any estimate for advantages derived.

CHIMNEY POTS.

Sir—A correspondent, J. R. B., in your last number, as a remedy against the unsightly but unfortunately not altogether uselessness of chimney pots, (although never applied as they only ought to be), calls on builders to try the experiment of flues in the form of a tin coach horn, with the large end upwards. I am quite inclined to believe that such a trial would be successful, but if applied to the whole length of (say) a 40 feet flue, as I understand him to intend, any useful difference in its diameter would, I fear, so swell the stack, as, if conveniently practicable, would at once banish the beautiful shafts of the old English style, and lead, in too many instances, to no very sightly substitutes in that or any other style. What if the principle were applied to the last five or six feet merely; even then it might perhaps lead to deformities too frequently; this however is a secondary consideration, and the genuine architect can never be at a loss to get over such a difficulty, since it is his business to surmount difficulties, and therein prove his superiority to mere pretenders.

J. R. B. will perhaps favour us with his experience in, and valuable remarks on, the practicability of his suggestions.

I am, Sir, your obedient servant,

G. W. E.

February 16, 1841.

ENGINEERING WORKS OF THE ANCIENTS, No. 2.

Continuing our notes from Herodotus, the present paper will principally relate to the Egyptians, whose works like those of the Babylonians, have an interest for us, as giving rise also to a school on which Greek engineering was founded. It is one of the most ancient of which we possess authentic monuments and records. The Egyptians like the Babylonians principally devoted themselves to hydraulic engineering, in which they made great progress; their other works also afford convincing proofs of their attainments in other departments of the art. The account of Egypt in Herodotus might be almost termed a history of engineering in that country, where it was called into play as one of the great instruments of national advancement, the exploits of a prince consisting as much in the works he executed, as in the victories which he obtained. This is one of the features of a system of polity, to which Egypt was indebted for great social progress, and an exemptiom from many of the evils which afflicted surrounding nations. If from moral causes Egypt never attained the intellectual perfection of the Greeks, yet by the extent of its public works the country was brought into a high state of cultivation and productiveness, so as to make it for centuries the granary of Europe. It was less owing perhaps to the fertility of the soil, than to the facilities afforded as to internal communication, that the resources of Egypt were made so extensively available.

CAUSEWAY OF CHEOPS.

Cheops, it is said by our author, degenerated into extreme profligacy of conduct, and oppressing the Egyptians in every way, he proceeded to make them labour servilely for himself. Some he compelled to hew stones in the quarries of the Arabian (query) mountains, and drag them to the banks of the Nile; others were appointed to receive them in vessels and transport them to a mountain in Libya. For this service a hundred thousand men were employed, who were relieved every three months. Ten years were consumed in the hard labour of forming the road, through which these stones were to be drawn; a work cited by Herodotus as equal in difficulty to the pyramid itself. This causeway was five stadia in length, forty cubits wide, and its extreme height thirty-two cubits, the whole of polished marble, adorned with the figures of animals. So far our author, a modern account by Pococke and Norden, says that there is still a causeway running part of the way from the canal which passes about two miles north of the pyramids. This extends about a thousand yards in length, and twenty feet wide, built of hewn freestone. It is strengthened on either side with semicircular buttresses, about fourteen feet diameter, and thirty feet apart. There are sixty-one of these buttresses, beginning from the north. Sixty feet farther it turns to the west for a little way, then there is a bridge of about twelve arches, twenty feet wide, built on piers that are ten feet wide. Above one hundred yards farther there is another bridge, beyond which the causeway continues, about one hundred yards to the south, ending about a mile from the pyramids where the ground is higher. The reason for building this causeway and keeping it in repair seems to be the lowness of the country, the water lying on it a great while.

THE GREAT PYRAMID.—THE MIDDLE PYRAMID.—THIRD PYRAMID.

As we are rather giving common-place notes from the individual authors, than complete accounts of the works, we have less compunction in copying what Herodotus says of the much-written subject of the pyramids. Having described the causeway just mentioned, our author goes on to say that a considerable time was consumed in making the vaults of the hill on which the pyramids are erected. These he intended as a place of burial for himself, and were in an island which he formed by introducing the waters of the Nile. The pyramid itself was a work of twenty years: it is of a square form; every front is eight plethra long, and as many in height; the stones very skilfully cemented, and none of them of less dimensions than thirty feet. The ascent of the pyramid was regularly graduated by what some call steps and others altars. Having finished the first flight, they elevated the stones to the second by the aid of machines constructed of short pieces of wood (supposed by some to be the pulley); from the second, by a similar engine, they were raised to the third, and so on to the summit. Thus there were as many machines as there were regular divisions in the ascent of the pyramid, though in fact there might be only one, which being easily manageable, might be removed from one range of the building to another, as often as occasion made it necessary; both modes have been told me, says Herodotus, and I know not which best deserves credit. The summit of the pyramid was first of all finished off; descending hence, they regularly completed the whole. Upon the outside were inscribed in Egyptian characters, the various sums of money expended in the progress of the work for the radishes, onions and garlic consumed by the artificers.

The middle pyramid, attributed to the daughter of Cheops, is stated to have an elevation on each side of one hundred and fifty feet.

Chephren, the brother of Cheops, is mentioned as the builder of the third pyramid, which was less than his brother's. It has no subterraneous chambers, nor any channel for the admission of the Nile. The ascent is entirely of Ethiopian marble of divers colours, but it is not so high as the larger pyramid by forty feet. The pyramid stands on the same hill as that of Cheops, which hill is near one hundred feet high.

DOCKS.

Psammitichus, as a reward for services rendered in war, conferred on the Ionians and Carians certain lands, which were termed the Camp, immediately opposite to each other, and separated by the Nile. They were the first foreigners whom the Egyptians received among them; and "within my remembrance, in the places which they formerly occupied, the docks for ships, and vestiges of their buildings, might be seen," continues our author.

CANALS.—RED SEA.—SLUICE.—BOLBITINIAN.—BUCOLIC.—MEMPHIS.—AN ENGINEERING KING.—CIVIL ENGINEERS.—ENGINEERING THREE OR FOUR THOUSAND YEARS AGO.—SURVEYORS.

Pharaoh Necos, the son of Psammitichus, was, according to Herodotus, the prince who first commenced the celebrated canal leading to the Red Sea, which Darius, King of Persia, afterwards continued. The account of Herodotus is this:—The length of the canal is equal to a four days journey, and it is wide enough to admit two triremes abreast. The water enters it from the Nile, a little above the city Bubastis; it terminated in the Erythrean Sea, not far from Patumos, an Arabian town. They began to sink this canal in that part of Egypt, which is nearest Arabia. Contiguous to it is a mountain, which stretches towards Memphis, and contains quarries of stone. Commencing at the foot of this, it extends from west to east, through a considerable tract of country, and where a mountain opens to the south is discharged into the Arabian gulph. From the northern to the southern, or as it is generally called, the Erythrean Sea, the shortest passage is over Mount Cassius, which divides Egypt from Syria, whence to the Arabian gulph is exactly a thousand stadia. The way by the canal, on account of the different bends, is considerably longer. In the prosecution of this work under Necos, no less than one hundred and twenty thousand Egyptians perished. He at length desisted from his undertaking, being admonished by an oracle, that all his labour would turn to the advantage of a barbarian. Diodorus Siculus gives an account which brings the progress of the work down to the time of the Greek kings; he says:—The canal reaching from the Pelusian mouth of the Nile to the Arabian gulph and Red Sea was made by hands—Necos, the son of Psammitichus, was the first that attempted it, and after him Darius the Persian carried on the work somewhat farther, but left it at length unfinished; for he was informed by some, that in thus digging through the isthmus he would cause Egypt to be deluged, for they showed him that the Red Sea was higher than the land of Egypt. Afterwards Ptolemy, the Second finished the canal, and in the most proper place contrived a sluice for confining the water, which was opened when wanted to sail through, and was immediately closed again, the use of it answering this purpose extremely well. The river flowing through this canal is called the Ptolomean, from the name of its author. Where it discharges itself into the sea it has a city named Arsinöe. So far our authors; we may farther mention that the site of this canal, although it could not be found by Norden, was distinctly ascertained by the scientific commission attached to the French army, and that plans have been proposed by Mehemet Ali for restoring.

Of the seven mouths by which the Nile disgorges itself into the sea, two are stated to have been produced by art, the Bolbitinian and the Bucolic,* a circumstance that shows the importance which the Egyptians attached to ready access with the sea, as a means of promoting their maritime commerce. This, fostered as it was by the extent of inland navigation, was, whether in the hands of foreigners or natives, carried on upon a large scale, embracing not only domestic productions, but also the transit trade with India and the East, of which Egypt was so long the channel, and the value of which, as our subsequent observations will show, was appreciated at an early period. It is true that these two canals were also required for agricultural purposes, but we think we do not err in attributing also another motive. The order in which the seven branches of the Nile lie from

* Herodotus Euterpe.

east to west, which will show the position of the artificial branches, is thus; the Pelusian, the Mendesian, the Bucolic, the Sebennitic, the Saitic, the Bolbitine, and the Canopic.

One of the earliest hydraulic operations to which we find allusion made, was the recovery of the site of Memphis from the water by which it was overflowed. This is attributed to Menes, respecting the date of whose reign some diversity of opinion exists, Herodotus calling him the first sovereign of Egypt, while by Diodorus Siculus, he is styled the first king of Memphis, a view which is supported by many leading moderns. According to Herodotus the river before that time flowed entirely along the sandy mountain on the side of Libya, but by Menes its course was diverted. A hundred stadia from Memphis a bank was constructed, while a canal was led between the mountains, or according to some cut through them, to receive the stream. Of the ancient bed the site is still to be traced; Savary observes that it may be found west of the lakes of Natroun, extending for a considerable distance. Menes is also said to have sunk a lake to the north and west of Memphis, communicating with the river, which from the situation of the Nile, it was impossible to effect towards the east. On the spot thus rescued from the water was built the city of Memphis, by which Thebes was afterwards supplanted. We have here an instance at an early period of the diversion of a large river, and the recovery of a considerable space of ground, operations requiring a degree of skill in the plan, and energy in the execution which must give us a favourable idea of the engineer-king, who thus founded a city and a dynasty. It might at this place be a speculation whether it was not to the success of this work that Menes and his followers owed their kingdom and their authority, an hypothesis which if substantiated would be a unique addition to the claims of the profession. Cultivated as it has been by kings and warriors, it shares this honour with the law, with which the establishment of this new fact would give another step towards an equality of privileges—many owing their kingdoms to their legislation, and acquiring the exercise of authority by showing the necessity for it. Homer mentions the practice of medicine by powerful chiefs, but this art although it may have saved crowns, never seems to have gained them. We have however another subject of interest to the profession to lay before them—suggested also by the works of Menes. Our author informs us that even in his time, when Egypt was under the dominion of the Persians, the artificial channel was annually repaired, and regularly preserved; for he says had the river once broken its banks, the town of Memphis would have been greatly endangered. The necessity for the regular preservation of these works would undoubtedly require their being placed under the care of duly appointed officers, the exercise of whose functions being specially devoted to one object would lead to the formation of a particular class, essentially civil engineers. The same class of officers would also be required in other parts of the country, and thus we may conceive the organization at the distance of two milleniums and a half of a regular *water staat*. We have here a dawning of the system of a government corps of engineers, such as exists in most countries abroad at this moment, for there must have been in Egypt little opportunity for private practice when so much depended on the government. Private practitioners of engineering, although employed by governments, we shall perhaps hereafter find to have sprung up in Greece—so much split up in petty states, many of which would have no demand for permanent officers.

A princess, whom Herodotus calls Nitocris, is said by him to have floated to death a number of Egyptians. Having been appointed sovereign on the death of her brother, who had been murdered by the Egyptians, to be revenged on them she had a large subterranean apartment constructed, to which she invited a great number of those, whom she knew to be the principal instruments of her brother's death, and then by a private channel introduced the water of the river among them, and so destroyed them.

To Sesostris is attributed the execution of the general system of canals with which Egypt is provided, the number of which still existing is estimated by Savary at eighty, several of which are fifty, eighty, or a hundred miles long, and like rivers. On the return of Sesostris from his foreign conquests about three thousand two hundred years ago, he employed the captives of the different nations in collecting the immense stones which were employed in the temple of Vulcan. They were also, says our author, compelled to make the vast and numerous canals, with which Egypt is intersected. In consequence of their involuntary labours, continues the historian, Egypt which was before conveniently adapted to those who travelled on horseback or in carriages, became unfit for both; the canals occurring so often, and in so many winding directions, that to travel on horseback was disagreeable, but in carriages impossible. The inhabitants of the inland parts however benefited by obtaining a more regular supply of water for domestic and agricultural purposes.

In his next paragraph Herodotus informs us of the well known origin of surveying. Sesostris made a regular distribution of the lands, and assigned to each Egyptian a square piece of ground. Whoever was a sufferer by the inundation of the Nile, was permitted to make the king acquainted with his loss, and certain officers were appointed to inquire into the particulars, that no man might be taxed beyond his means. To this circumstance the historian assigns the origin of geometry, and from Egypt it was afterwards communicated to Greece. Here we have the origin of surveying, and of distinct officers engaged in its pursuit at a period according to received chronology, about 1350-60 years before Christ, now three thousand two hundred years, an antiquity, of which few professions are able to boast the equal, and one of the many circumstances in the history of civil engineering which show its early progress. Thebes was then the great school of Egyptian learning, and where geometry and surveying are supposed particularly to have flourished. It was perhaps to the government surveyors that the care of the canals of Memphis and other places was intrusted, so that then as it frequently is now, the surveyor might have been the probationer to the civil engineer. We do not apologize for troubling our readers with these observations, for we know that they like ourselves must feel the same interest in remembering that our's is no profession of to-day, but one which centuries ago, as now, was a powerful contributor to the progress of civilization, and the well being of the human race.

FOUR AND SIX-WHEELED ENGINES.

Sir—There is a subject connected with the question of four and six-wheeled engines as to their relative advantages when traversing curves, which has not, I believe, been sufficiently examined into; will you allow me, therefore, through the medium of your valuable journal, to call attention to it.

It has generally been assumed, because the distance between the fore and hind wheels is greater in six than in four-wheeled engines, that there must of necessity be greater danger of the former running off the rails when traversing curves.

If the engines moved with mathematical precision in the path laid out for them, this would undoubtedly be the case; but in consequence of the irregularities and inequalities of the rails, and the play which it is necessary to allow on this account between the wheels and the rails, the motion of the engine is varied from its true direction. Any person who has observed the action of a locomotive when passing rapidly along the rails, will have noticed that its track is not straight, but partakes of a serpentine movement, the fore wheels going from side to side in tolerably regular vibrations, and the greater the velocity the greater this effect, also the less the distance between the fore and hind wheels the greater this effect; for as the play is the same in all cases, the angle formed between the direction of the rails and the engine during these vibrations, will depend on the distance of the points of bearing; and it is probably in some measure attributable to this effect that four-wheeled engines have been found to go off the rails when travelling over straight parts, while such an accident was never, I believe, known to occur to a six-wheeled engine, unless from some foreign cause.

The distance between the centres of the wheels in the one case is about 7 feet, and in the other about 10 feet, and the play given to the wheels is half an inch. The greatest obliquity, therefore, that the six-wheeled engine can take up is ·5 of an inch in 10 feet, or 1 in 240, while in the four-wheeled engine it is ·5 of an inch in 7 feet, or 1 in 168. It would, perhaps, be too much to assume that the engine vibrated to the whole of this amount, but, to be quite on the safe side, we will take half of it, in which case the sine of the angle of obliquity between the direction of the engine and that of the rails will be expressed by $\frac{1}{480}$ in the six-wheeled engine, and $\frac{1}{336}$ in the four-wheeled engine, when travelling on the straight parts; and it will be seen that this apparently slight difference gives the advantage to the six-wheeled engine in all curves used in ordinary practice.

The sine of the angle at which an engine meets the rails on a curve supposing the engine to be moving mathematically true, will be $\frac{l}{2\,r}$, l being the distance between the centres of the fore and hind wheels, and r the radius of the curve in feet. The advantage in favour of the four-wheeled engine in this respect, on curves of the same radius, would therefore be as $\frac{7}{2\,r}$ to $\frac{10}{2\,r}$; but to this must be added in practice the angle of obliquity due to the vibratory motion of the engine;

hence, when both engines are in their most disadvantageous positions on a curve, the sines of the angles they form with the rails will be nearly as $\frac{7}{2r} + \frac{1}{336}$ to $\frac{10}{2r} + \frac{1}{480}$, and when these angles are equal to each other, we have $2r + \frac{1}{336} = \frac{10}{2r} + \frac{1}{480}$, or $r = \frac{161280 \times 3}{288} = 1680$ feet $= 560$ yards. That is to say, that supposing the deviation from the true position of the engine, due to the play between the wheels and the rails to be no more than a quarter of an inch in its length, the six-wheeled engine meets the rails at a more favourable angle, and is consequently less likely to run off them on all curves in which the radius exceeds 560 yards; on curves of a less radius the four-wheeled engine begins to have the advantage.

I am, Sir,
Your obedient servant,
W. H. Barlow.

IMPROVEMENT ON ECCENTRIC RODS.

Sir—Among the numerous readers of your highly esteemed Journal perhaps there are many to whom the subject of this communication will appear of little importance, I therefore apologize for once more imposing it upon your pages.

In your present month's number (page 66,) I observe a communication signed H. E., in which your correspondent points out several inconvenient conditions as inseparable from the system of two eccentrics, in reply to which, with your permission, I beg to make the following remarks. I will notice these conditions one by one after the same order H. E. has pointed them out.

First. I do not clearly see how it is possible to give the lead *at all* either with or without a complication of levers unless the eccentric precedes the crank in its *action*. Even supposing the working the valve, when going forward, by the upper pin of the double lever to be inseparable from the system, it has in my opinion a peculiar advantage, in this respect, over the four eccentrics, the rods of which are kept in gear partly by their own weight, for instance. Suppose some derangement to take place in the reversing apparatus of an engine fitted with with the four eccentrics; the two suspended eccentric rods would fall upon the lever studs of the valve motion, and very probably cause a most serious crash. Now with the double ended eccentric rods the case would be rather different; their falling from the upper to the lower studs of the double levers would only reverse the action of steam upon the pistons, and as the engine-man has always the power to shut off the steam, he could *instantly* prevent the reverse motion of the engine.

Second. The centre of the double lever shaft may be situated above or below the line C, E, just as circumstances may require, but it is requisite to fix the eccentric so that it shall be exactly perpendicular to the centre of the shaft and crank axle, when the piston is at either end of the cylinder. I do not see any just reason why this should be considered as an inconvenience.

Third. I beg to state the amount of lead is *not* dependant upon the length of the eccentric rod, as H. E. has stated, but it depends upon the angle at which this rod works with the centre of the lever shaft and crank axle.

Fourth. It is possible to construct the valve motion so as to give the power of increasing or decreasing the amount of lead both ways, but as this would cause an additional number of parts, and consequently render the system more complex, I will admit of "the lead being determined must remain invariable."

With the four eccentrics, providing they are all independent of each other, that is, fixed on the shaft separately, you certainly have the advantage of varying the amount of lead; but the eccentrics are not always *independent* of each other, they are very frequently *cast all together*. In this latter case the lead, for both ways, is determined in the eccentrics, and of course remains *fixed*, therefore, you cannot increase it one way without diminishing it the other, this H. E. has pointed out to be the *most serious objection* to the two immoveable eccentrics. With the four independent eccentrics the lead may be varied correctly both ways it is true, still this is a rather particular point, and requires considerable time to effect the alteration accurately, consequently, I am informed, is very seldom resorted to. I have hitherto been totally unaware of what H. E. has stated in his eighth paragraph.

Another correspondent (An Apprentice in Glasgow,) remarks that "I have described the contrivance for working an engine with one eccentric as an invention of my own, although it has long been quite common in that country." I certainly have described it as my own, and I had every possible reason for doing so. I was not aware that it had ever been applied *successfully*, that is, exactly *correct in every point*. But I am aware, and well aware too, that engines, for winding purposes, have long been common in mining districts with one immoveable eccentric, and a double lever for reversing; and I have been informed that this contrivance has frequently been applied to engines for marine purposes, but in *both cases* has failed in point of correctness. This has been the consequence of not fixing the eccentric rods at the *proper angle*, &c.

Notwithstanding all that H. E. has said, he, together with the Apprentice, appears to be in favour of the two immoveable eccentrics.

I remain, Sir, your's, very respectfully,
J. C. Pearce.

Leeds, Feb. 8, 1841.

ON THE CONSTRUCTION OF IRON BRIDGES.

When we consider the superiority of iron bridges, says M. Polonceau, in his notice of the new plan of iron bridges invented by himself, and of which the bridge of Erdre (at Nantes) affords a good specimen, we are astonished that so few have been constructed in France, and even in England, where it is so much the custom to make use of iron, and where it is so plentiful. If these bridges are compared with stone bridges, it will be found that they are constructed with much less difficulty, and that they are considerably less expensive, and that when they have cast-iron roadways they are not inferior, if not superior, to them in durability. In fact, cast-iron is more durable and more strong than stone; it is better adapted to bridges with large arches, because the weight of an arch in iron being much less than that of an arch in stone of the same span, the destruction of the piles and abutments is less to be apprehended, and on this account can be constructed at less expense.

Compared with wooden bridges, bridges of cast iron cost about a half less than bridges of that kind which have abutments in stone; but their duration is indefinite, and the keeping wooden bridges in repair is attended with great expense, while the cost of repairing iron bridges is a mere trifle. The difference of expense between solid iron bridges and that of well executed suspension bridges is not so considerable as might be supposed.

In endeavouring to explain the causes which have prevented these kind of bridges from being more generally used, continues M. Polonceau, we discover three principal ones which have been unfavourable to their general adoption.

First—The great expense of iron, and the uncertainty in the casting of the larger pieces, before the year 1830.

Second—The great expense of the only two iron bridges constructed in France before that time. The cost of the *Pont des Arts* amounted to 900,000f., and that of Austerlitz to two millions and a half, not including the approaches.

Third—The accidents and repairs required by these two bridges.

Those works of art were constructed on two entirely opposite principles. In the bridge of Austerlitz the arches, and the triangular pieces above them which support the roadway, are composed of portions of the arcs in frame-work, and are attended with all the inconveniences consequent on this plan; and further, these frame-work pieces are small, much ornamented, and are of unequal thickness, and to this may partly be attributed the accidents which take place.

The plan of construction adopted in the *Pont des Arts*, which is composed of large arches connected together by pieces of iron, is more rational; but the principal arches are not sufficiently strong, and owing to the variations in the thickness of the castings, the metal contracts and expands unequally. In each of these bridges durability has been sacrificed to lightness and elegance, which occasions frequent fractures in the least durable parts.

Southwark Bridge, in London, one of the most remarkable of the kind, is composed of portions of arches, like the bridge of Austerlitz, but those are plain, and are not carved, although they are more than two metres high, and the method on which they are arranged is much superior to that adopted in the bridge of Austerlitz. The strength and entire preservation of the Southwark bridge is to be attributed entirely to the great quantity of iron used, which was procured at enormous expense, and amounted to more than fifteen millions of francs. It is probable that the great expense of this beautiful structure has prevented its being imitated.

The natural consequence of what has been stated is, that it is impossible to erect any more iron bridges in France, unless a new plan could be adopted of constructing them on more durable principles than those kind of bridges have ever been constructed, and at less expense than the English bridges. This double problem M. Polonceau has solved, by constructing, on an entirely new system of his own invention, the Carrousel bridge at Paris.* It is on this plan of making bridges, now well known by the name of Polonceau bridges, that the bridge of Erdre is also constructed.—*Echo du Monde Savant.*

* See drawings and description of this Bridge in the Journal, Vol II. page 79.

RAILWAY SIGNALS AND REGULATIONS.

We last month gave a copy of the resolutions passed at the railway conference at Birmingham; since then a full account of their proceedings has been published, with the code of signals and regulations proposed to be adopted on all railways throughout the United Kingdom, a copy of which we give in full.

RULES AND REGULATIONS, PROPOSED TO BE OBSERVED BY ENGINEMEN, GUARDS, POLICEMEN, AND OTHERS, ON ALL RAILWAYS.

Orders to Enginemen and Firemen.

I.—No locomotive steam engine, except in case of some extraordinary necessity, shall pass along the wrong line of road—that is to say, on the right hand line as it moves forward—but shall, in all cases, observe the same rule of the way as on the turnpike roads, by proceeding along the left-hand line. And every engineman and fireman shall keep a good look-out all the time the engine is in motion. And no person, except the proper engineman and fireman, shall be allowed to ride on any locomotive steam engine or tender without the special licence of the directors, or of the engineer or manager of the railway.

II.—In case of accident, if any engine shall be unavoidably obliged to pass on the wrong line of road, the engineman shall always send his assistant, or some other person, back beyond the nearest stopping place or shunt, before the engine moves backward, to warn any engine coming in the opposite direction; and if dark, the man who goes back in advance of a returning engine shall take a light, and make a signal, by waving the same UP and DOWN to any coming engine to stop; and the engineman of the engine moving on the wrong line shall make constant use of the steam-whistle, and must not move in the wrong direction further than to the nearest shunt, and being arrived there, shall proceed instantly to remove the engine off the wrong line of road.

III.—All engines travelling in the same direction, shall keep half a mile at least apart from each other; that is to say, the engine which follows shall not approach within half a mile of the engine which goes before.

IV.—No engineman shall, at any time or under any circumstances, leave his engine or train, or any part of his train, on the line of way, without placing a man in charge of the same, to cause the proper signals to be made to prevent other engines from running against them.

V.—Enginemen having charge of goods or luggage trains shall always exert themselves to keep out of the way of coach trains, by shunting, if necessary; and, if doubtful of getting out of the way of a coach-train, shall direct gatemen and plate-layers to make signal to coach trains that a luggage train is before them.

VI.—No engine, carriage, or wagon, or train of carriages or wagons, whether loaded or unloaded, shall (except only in case of absolute necessity, to prevent accident or collision) stop upon the line of any highway, so as to interrupt the passing along such highway or public road, whether the same be at or near to any of the stopping places on the railway or not.

VII.—No engine shall be allowed to propel before it a train of carriages or wagons, but shall in all cases draw the same after it, except when assisting up an inclined plane, or in case of any engine being disabled on the road, when the succeeding engine may propel the train *slowly* as far as the next shunt, or turn-out, at which place the said propelling engine shall take the lead.

VIII.—In the event of the road being obscured by steam or smoke, (owing to a burst tube, or from any other cause,) any engine or train coming up shall not immediately pass through the steam or smoke, but the engineman shall stop at a sufficient distance to prevent a collision, and shall ascertain that the way is clear and safe before attempting to proceed.

IX.—If a coach train be stopping to take up or set down passengers, on the road, or for any other cause, luggage trains are not allowed to pass it, while so stopping, on the opposite line; and if the engineman of a *coach train* sees another coach train stopping on the road, he must slacken speed as he approaches it, and blow his whistle, to give notice to passengers belonging to the stopping train, that another train is about to pass them.

X.—In going down any inclined plane, every engineman having charge of a luggage train, shall take care that he has full and competent control over the speed of his train, by pinning down, or causing to be pinned down, his wagon breaks, fewer or more, according to the size or weight of the train, whether there be a luggage break-man with the train or not. And in case of accident for want of this proper control over the speed, the engineman shall be held responsible. And the policemen at the top of the inclines shall, and are hereby charged to, assist in pinning down the breaks, when desired so to do by the engineman of the train.

Rules to be observed during a Fog, or in Thick Weather.

XI.—Whenever a coach train stops at any of the stations or places for taking up or setting down passengers, (during a fog, or in thick weather), the gateman or policeman of the station shall immediately run 400 yards behind the train, or so far as may be necessary to warn any coming engine, in order to prevent its running against the other; and all enginemen shall slacken speed in foggy weather, and proceed at a slow pace at an ample distance from, and as they approach, each of the stations and stopping places, in order that they may have the complete control of and be able to stop their engines and trains without risk of running against any train which may happen to be waiting at such station or stopping place. And in case any engine (whether with coaches or luggage waggons, or without) shall stop in foggy or thick weather in any part of the road where there shall be no plate-layer to render assistance, the fireman shall immediately run back 400 yards, or so far as may be necessary, to warn and stop any other engine coming in the same direction.

In foggy weather, enginemen are cautioned to make frequent use of their steam-whistle when they approach any station; also, whenever they are obliged to stop on the road, or when, from any cause, they are obliged to go slower than usual, in order to prevent accidents from trains which may be following on the same line.

Order to Gatemen and Policemen.

XII.—All policemen and gatemen are required, when a luggage train approaches their several stations, and before she comes up, to go on the line and inspect both sides of the train, to ascertain whether any of the loading (particularly bags of cotton or wool) have slipped so as to *overhang* the waggon more than when first loaded; and if such be the case, to make immediate signal for the *train to stop*, in order that the loading may be put right and fastened on again before the train proceeds.

N.B.—All enginemen, firemen, guards, policemen, gatemen and others to whom the foregoing rules may apply, are held responsible for their strict execution and observance; and they shall report to the directors, or to their immediate superintendent, any servant of the Company who shall refuse or neglect to comply with the regulations hereby ordered to be observed.

CODE OF SIGNALS RECOMMENDED TO BE OBSERVED ON ALL RAILWAYS.

By Night.—The *white* light, stationary, indicates that all is right, but if waved *up* and *down*, is a signal to stop; if waved *to* and *fro*, sideways, to proceed cautiously.

The *red* light, stationary, is a signal *always to stop;* if on a moving train, it is a caution to all following trains to keep the required distance.

By Day.—The *red* flag, or ball disc, is the signal always to stop.

The *blue* flag, or ball, is to stop second class coach trains or luggage trains, for the purposes of traffic.

The *black* flag is used by plate-layers, to indicate that the road is undergoing repair, and that trains must pass slowly.

It is to be understood, that any flag, or hat, or lamp, of whatever colour, waved up or down, is a signal to *stop.*

Regulations as to Signals.—1. Every train on the railway shall show a red bull's eye, or reflector lamp, on the last carriage or wagon; and the guards of the coach trains, the breaksman of the luggage trains, and the engineman of an empty engine, or, with a wagon train without a breaksman, shall see to and be held responsible for, the execution of this order; and if a coach, or truck, or horse-box, or wagon, be attached to or detached from a train on any part of the road, the guard, or breaksman, or engineman shall immediately change and replace the red bull's eye, or reflector lamp, so that the same may still be in the *rear* of the last carriage or wagon in the train, showing backward.

2.—Every engine tender must carry a lamp, so fixed as to admit of being turned round, exhibiting a *white* light forward, and a *red* light backward, in whichever direction the engine may be moving.

3.—Every gateman or policeman shall light his gate or station lamp at dusk, and shall have his hand lamp constantly trimmed and burning, and ready to give such signals as may be required.

4. If a coming engine or train be required to stop to take up passengers, a *blue* light must be shown in the gate-lamp; otherwise the common *white* light.

5.—If a train approaches when a previous train has passed through, only a few minutes before, the gateman shall signify this circumstance to the engineman by the waving of his hand-lamp *to* and *fro*, sideways, which means that caution is required; on which signal all enginemen are required to go slowly and keep a good look-out.

6.—But if a gateman, owing to some accident, or any extraordinary cause, wish to stop an engine which is approaching, he must show his *red* light, and must also wave his hand-lamp *up* and *down*, up to the height of his head, and then down to the ground, till the engine comes up; and all enginemen are required to stop at either of these signals being given; and a gateman must make this signal to an approaching engine, if a previous engine has passed through this gate only one or two minutes before.

N.B.—The *red* flag, or ball, must be used in the day, in the same manner as the *red* lamp by night.

Rockets or *blue* lights are extraordinary signals, and when an engineman sees them he must immediately stop to ascertain their cause.

Engine Whistle.—7. When *one long whistle* is given, it is a signal to gate keepers, policemen, and others in front, that an engine is coming, and this signal is to be used on approaching public roads, during a fog, or when a first class train approaches a station where a second class train is stopping, and generally as a caution when required, for persons on the line to keep out of the way.

But when an engineman wishes to make signal to the guards, or breaksmen *on the train*, that they are to put on their breaks and stop, he must give a *quick succession of whistles*, making an interrupted, tremulous, or vibrating sound; and all guards or breaksmen, whether with coach or luggage trains, hearing this signal, *must immediately* hold hard on the break or breaks under their charge, so as to stop the train *as quickly as possible*.

NEW INVENTIONS AND IMPROVEMENTS.

IMPROVEMENTS IN STEAM ENGINES.

Thomas William Parkins and Elisha Wylde, of Portland-street, Liverpool, Engineers, for an improved method of making and working locomotive and other steam engines. Enrolment-office, Jan. 12, 1841.

This improved method relates to the slide valve and throttle valves of steam engines, and consists in a novel mode of constructing them, so as to facilitate the action of the valves, to place them under more perfect control, and to afford a freer entrance to the steam cylinder under certain circumstances.

The first arrangement is for working the slide valve without the use of eccentrics, in order that it may open almost instantaneously at the time the engine is passing the centre. For this purpose a lever is fixed upon the cross-head working in a link connected to a second lever fixed on a shaft or weigh-bar across the engine, whereby a rocking motion is produced. On the other end of the weigh-bar a double lever is fixed, carrying two studs above and below the centre of the said shaft or weigh-bar, for the forked rod to work upon. One end of this rod is attached by a working joint to a fourth lever fixed on the weigh-bar, which gives motion to the slide valve at each succeeding return of the cross-head to the extremity of its stroke. The levers are so arranged that the slide valve is always kept wide open at the period of the engine passing the centre, instead of being shut, as is always the case when an eccentric is used, and by which means the full effect of the steam is employed up to the last moment.

Secondly, a new method of constructing the slide valve, being an improvement upon the old D slide valve, is described; the object being to get rid of almost the whole of the immense steam pressure which always presses upon slide valves of the present construction, and at the same time to give a free passage for the escape of the waste steam throughout the whole of the stroke. This slide valve consists of a hollow square ring of metal, working between two surface plates, the lower one being the side of the cylinder, the upper one provided with set screws or other suitable means of adjustment. The hollow ring beds upon the cylinder, and is furnished with a square metallic packing upon its upper surface, which, abutting against the adjusting plate, makes the slide valve perfectly steam tight. The slide valve is made long enough for the eduction passage to remain open while the steam way is closed, and *vice versa*.

Thirdly, the patentee describes a peculiar mode of constructing the regulator or throttle valve of steam engines, especially as applied to locomotive engines, so as to afford a ready and convenient means of admitting steam to either one of the cylinders only, or to both of the cylinders at the same time. The regulator or steam passage is in this case a flat surface, with passages through it at the distance of one end of the cylinder from the other, and so disposed that when the regulator's handle is inclined to the starboard, steam is admitted into the cylinder on the larboard side of the engine; on inclining the handle over to the larboard, the steam is also admitted to the starboard cylinder, but on placing the regulator handle in a vertical position, the throttle valve is closed, and the steam communication cut off from both cylinders.

A fourth improvement consists in certain additions to the machinery for working the slide valve, so as to cause the steam to work in the cylinder expansively, in order to economise fuel; for this purpose two slots are made in the top of the link in which the cross-head works, in which two bell-crank levers work on pivots; to the under side of the engine framing, a roller is fixed between the two levers, being a fulcrum to act against when they are alternately pressed down by the roller (attached to the lever on the cross-head), which works in the link passing over them; this causes the link to advance sufficiently to close the slide valve, or, in other words, to shut off the steam at the determined portion of the stroke.

Finally, an arrangement is exhibited for reversing the direction of the steam, so as to stop the engine and drag the wheels whenever circumstances render such a procedure necessary. In order to accomplish this movement, a handle is placed on one side of the foot plate, which is connected to a bell-crank lever, connected by a link to the tappet-rod. This handle is to be secured by a spring guard, and when in a vertical position the tappet-rod will be entirely out of gear; when it inclines forward, it will be in gear for going either forward or backward; and when it inclines backward, the tappet-rod will be lifted on to a stud on the third lever above the centre of the shaft connected with the link on the other side, which will stop the motion of the engine almost immediately, as the steam will be admitted into the cylinder before instead of behind the piston, which will drag the wheels and bring up the engine.

The claim is to 1. The construction of the slide valve, being a hollow ring through which the steam is either admitted or exhausted, and the means used for keeping the said slide valve steam tight.

2. The combination of the machinery for moving the valve, especially the construction of machinery for moving the said valve so as to work the steam expansively.

3. The construction of the regulator or throttle valve by which steam is admitted to either cylinder only, or to both cylinders at the same time.

4. The construction of machinery for moving the slide valve so as to cause the steam to enter the cylinder before instead of behind, and make it act against the piston.—*Mechanics' Magazine.*

TOOLS FOR BORING.

William Ash, of Sheffield, Manufacturer, for improvements in augers and tools for boring. Petty Bag Office, Dec. 24, 1840.

These improvements consist in the combination of cutters and guides with a shank or spindle. The cutters are rectangular pieces of steel somewhat resembling the cutting side of a centre-bit. The guides are helical pieces on the outside, of various sizes, the interior of which fits the shank or spindle. The spindle has a pointed screw at the end, the size of the thread varying according to the kind of wood to be operated upon; at some distance up, on the side of the spindle, there is a circular stop, there is also a square opening just above the worm, passing through the spindle. The helical guide, of the size required, is first put on the spindle, and a cutter inserted in the square aperture below it, where it is firmly fixed by driving in a wedge. If a larger or smaller hole is required, the wedge is struck out, when the cutter, &c. may be easily removed, and replaced with guides and cutters of the size required. Another form of guide is shown, consisting of a circular plate of metal, with a thimble in its centre, supported by two cross pieces from the outer edge. The first, or helical guide, however, is preferred, from its being longer, and also from its affording a channel for the ready escape of the chips, thereby clearing the hole as the cutter advances.

The claim is for the application of moveable cutters and guides to a shank or spindle, as described.—*Ibid.*

MACHINERY FOR CUTTING AND WORKING WOOD.

William Hickling Bennett, of Wharton-street, Bagnigge Wells Road, Gentleman, for improved machinery for cutting and working wood, Enrolment-office, Dec. 24, 1840.

The improvements comprehended in this patent are—Firstly, a new system of guides for boards while passing through the wood-cutting machines. The iron frame of the guides varies in shape in different machines; it forms a bed on which the guides traverse. The guides are formed of puppet-heads in pairs, one being fixed, the other moveable in order to hold and guide wood of different sizes. Moveable pieces slide over the inner vertical faces of the guides, and pressing down upon the upper surface of the wood it is thus held firm and steady.

Secondly, an improved mode of elevating and depressing the upper pair of rollers, when the wood is carried forward by their means. The axes of the upper rollers turn in blocks which slide up and down in grooves in the upright side frames of the machine. They are regulated by spur and bevel wheels, in conjunction with spiral springs, so that while the wood is firmly held, an elasticity is obtained by means of the springs, which allows any irregularities in the surface of wood to pass through the rollers.

Thirdly, an improved mode of admitting oil to the working parts, viz., the circular saws, shafts, spindles, &c., consisting of a cup with a tube at the bottom furnished with a stop cock, to be so adjusted as to allow any number of drops per minute to fall from the nipple into the channel leading to the bearings requiring lubrication.

Fourthly, an improved mode of sawing and dividing wood, so as to effect the planing at the same time; the arrangement being also applicable to veneer saws.

For this purpose, there are slots near the periphery of the circular saws, approaching as near to the edge as is consistent with due strength; in these slots side cutters are fixed, with their edges ground and set to the same angle as a plane iron. These cutters project slightly beyond the set of teeth of the saw; so that a shaving is continually taken off as the saw revolves. Or the edges of such slots in the saw plate may be turned up and used in lieu of detached cutters.

Fifthly, the application of the foregoing construction with two or more sets of circular cutters, so as to form two or more strips of plain or ornamental moulding. To accomplish this, two or more circular saws are mounted on one spindle between which, instead of washers, blocks are fixed, holding the cutters in the upper edges. These are circular and may be either plain or moulded, and they project sufficiently to perform the necessary operation as rapidly as the circular saws can rip the scantlings or boards into strips.

Sixthly, an improved mode of forming moulding and other cutters. These cutters may be of any required shape, and are attached to blocks, fixed on the saw spindle by grooves and feathers. They are made of thin steel plates screwed between two metal plates, which are worked down on each side so as to leave the steel edge projecting about $\frac{1}{16}$ of an inch.

Seventhly, a machine for preparing deals and baulks of timber for sawing. The wood to be operated upon is laid on a metal bed moved by a rack and pinion and slides on V pieces fixed to the floor. The apparatus for holding the timber is firmly secured to this bed; puppets are screwed to the sliding bed, their inner faces being made perfectly true. To these faces a cast-iron beam is attached vertically, so that it can be moved up and down, by nuts and screws, and serves to clip the upper part of the piece of timber.

The holding parts are capable of adjustment, so that timbers of any size may be held on different sides quite firmly, and brought up to the cutters by the traversing bed, for preparing a flat or square side thereto.

Eighthly, a machine for the same purpose, which may also be used for cutting mouldings or cornices and skirting-boards.

The wood in this case is secured to a traversing table and moved forward by a chain, rack and pinion, or other convenient means. Circular cutters are made to revolve above it, which strike the required pattern on the edge of the wood as it advances.

Ninthly, another machine for the same purpose, only in this case the machinery with the cutters approaches the wood instead of the wood approaching the cutters. This consists of a moveable bed traversing upon a fixed one; this bed carries the cutters with their driving wheels, &c. The wood is held upon a rising and falling table, while the machinery, cutters, &c. on the traversing bed are made to approach and perform the required operations on its surface and edges.—*Ibid.*

MACHINERY FOR PRODUCING PLAIN OR MOULDED SURFACES ON WOOD.

James Hodgson, of Liverpool, Engineer, for a new mode of combining and applying machinery for the purpose of cutting and planing wood, so as to produce plain or moulded surfaces. Enrolment-office, Feb. 3, 1841.

This invention consists in a mode of combining and applying machinery, whereby the patentee is enabled to employ a rotary spiral cutter for cutting and planing wood, so as to produce either plain or moulded surfaces. The machinery consists of a strong cast-iron frame, of any required dimensions, planed perfectly true on its upper edges, the feet or standards being bolted down to the flooring so as to give great firmness and stability. A cast iron table, also planed perfectly true, slides smoothly and equally upon the bed; this table is fitted with a cover or plate of wood on its upper surface, for the convenience of affixing thereto the wood to be operated upon by the machine.

Nearly in the middle of the bed there rises an upright frame or slide, in which the revolving spiral cutter is supported, and raised or lowered by a screw. The spiral cutter consists of a twisted bar of steel, or of iron and steel combined, the cutting edge passing from one end to the other in a spiral direction around the axis of its motion. This cutter is driven at a great speed, and revolves transversely to the grain of the wood. Such a cutter is adapted for the production of plain surfaces only; if mouldings are to be produced, the cutter must be worked out to the pattern intended to be given to the moulding. One mode of effecting this is stated to be by making a steel tool of the pattern required, which is placed beneath the spiral cutter while in rapid motion and gently raised as the cutter becomes indented. The edges of the pattern thus produced, are then filled up to an angle and sharpened, so as to make a clean cut in the wood moulding. The motion is supplied from a steam engine or other prime mover to a fast or loose pulley, from whence a series of wheels and bands communicate the necessary high velocity to the spiral cutter. The table on which the wood is fixed to be cut slides backward and forward upon the bed; a rack placed on its under side is acted upon by a pinion, driven by suitable traversing gear, and carried forward to the cutter. The backward movement is accomplished by a small handle on the axis of the pinion.

The claim is for the mode described, of combining and applying machinery so as to employ a spiral rotory cutter for cutting and planing wood so as to produce plain or moulded surfaces.—*Ibid.*

IMPROVEMENTS IN ROOFING AND SLATING BUILDINGS.

James Taaffe, of Shaw-street, Dublin, Slater and Builder, for improvements in roofing and slating houses and other buildings. Enrolment-office, Feb. 1, 1841.

These improvements consist of a novel mode of roofing and slating houses and other buildings, whereby much of the overlapping of the slates will be avoided, and roofs will be more advantageously formed and constructed with a much smaller quantity of timber and slates than at present used. And a roof formed according to the tenor of this patent, will, it is said, be much superior to that which could have been produced by a larger quantity of timber and slate applied as hitherto practised. In the first place, the rafters have a groove ploughed or otherwise made in their upper surface which is to be lined with lead, zinc, or other suitable metal to form water channels or courses. Two other modes of forming these water courses are shown: in the one case the rafter is divided into two and an angular metal gutter placed between; the other is formed by nailing two projecting strips of wood along the sides of the rafter, which form the sides of the channel. The rafters being furnished with proper water channels in some of these, or other convenient ways, slates are taken of such a width as to reach exactly from the centre of one water course to the centre of the next, so that the side joinings of each series of slate fall exactly over the centre of the water channels, by which means any water that may pass through between them is carried off into proper gutters. The first or lowest row of slates are screwed to the rafters by four copper screws, one in each corner, but in all the other rows, two screws, at the upper corners, only are used. Nails may be used instead of screws for fastening the slates to the roof, but the latter are preferred.

Where the slates overlap each other they are held together by clamps of this form, ⌶, made of copper or zinc. A notch is cut in the sides of the two upper slates, and a space cleared away in the two lower ones to admit the stem of the clamp. On the under side of the slates where they overlap, two throats or grooves are cut to prevent the water from running along underneath and so getting beyond the water channels.—*Ibid.*

COKE OVENS.

John Cox, of Ironmonger-lane, civil engineer, for improvements in the construction of ovens for the manufacture of coke, and other purposes. Jan. 19.—The oven is constructed of any convenient form, and of suitable materials. The best Stourbridge fire-bricks, with the joints closed by the same clay of which the fire-bricks have been made, is preferred. The roof of the oven is to be made very thin, and a broad flat shallow flue formed over it. The oven is charged in the usual manner, and the door closed, and as the gaseous products arise they are conveyed through proper small apertures into the flue above, where they are supplied with a sufficient quantity of atmospheric air to support combustion. They are consumed in the flue, and the heat transmitted downwards, for the purpose of promoting the process of coking through the roof of the oven. In some cases only part of the distilled products is consumed for the purpose of coking, and the remainder carried away in any convenient manner for any other purpose for which it may be required. In other cases the atmospheric air is admitted into the chamber with the coal, and thereby the products are consumed together with the coal. Sometimes retorts or other small vessels to be heated are set in the flue above the roof of the oven, and the products consumed as at first described.—The inventor does not claim the mode of consuming the distilled products in the same chamber as the coal; nor the application of flues to the bottom, sides, or ends of the oven; but he claims—First, The creation of heat by the admission of atmospheric air to the distilled products in or after they have left the oven, and the consequent combustion of the said products in or after they have left the oven.—Second, The same, whether the air be admitted at the top, bottom, sides, or ends of the oven.—Third, The same, whether the heat be employed for the process of coking only, or for manufacturing or other purposes as well.—Fourth, The promoting the process of coking by the application of a flue or flues over the top of the oven; whatever be the form or construction thereof.—*Inventors' Advocate.*

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

KING'S COLLEGE.

MR. HOSKING'S LECTURE.

We are glad to see that the Class of Engineering and Architecture is being carried on under such good auspices; our readers will see, by the following sketch, the course that Mr. Hosking proposes to adopt in the important department of instruction which falls under his direction. In expressing our approbation of the general views propounded by Mr. Hosking, we have to thank him and his colleagues at the College for their courtesy to us on this and so many other occasions.

After some introductory observations Mr. Hosking proceeded as follows:

"The printed paper already in your hands gives a general statement of the matters to which I shall have to direct the attention of the student, and I believe that every man who has had to learn these things for himself will readily admit that any instruction in them, however imperfect it may be, may become of the greatest practical value, by supplying, as a ground work for professional study, what has had, but too often, to be learnt in practice, and what, oftener still, is never learnt at all.

"We cannot hope here to make young men carpenters or masons, but we hope to make them better qualified to compose, describe, estimate and direct works of carpentry and masonry than they can be without such assistance as that we offer them. In becoming proficient as a carpenter, a mason, or a smith, a young man is apt to overlook the importance of other handicrafts in favour of that in which he has acquired confidence,—but a sound, and indeed a somewhat extensive practical knowledge of the modes of operating in all the leading crafts, of which the three I have mentioned, together with the bricklayer's craft, are the most prominent, is essential to the civil engineer, who only exists independently of the architect on the one hand, and of the practical machinist on the other, through his presumed superior practical skill in applying the operations of the carpenter, mason, bricklayer and smith, in connection with those of the navigator or earthworker and miner." The early life and experience of the late Mr. Telford are next referred to, with an account of his occupation in youth, and of his estimate of the value of such occupation to the intending engineer. Mr. Hosking then remarks:

"Such was the early education, and such were the matured opinions of the man who has left hardly a corner of our island without some important work to record his name.". . . . . " But Mr. Telford goes on, from the observations I have already quoted, to state thereupon his opinions and practice with regard to the education of the civil engineer: 'My readers,' he says, 'may *not* dissent from these observations, but few of them, unless practical men, will feel their full force. Youths of respectability and competent education, who contemplate civil engineering as a profession, are seldom aware how far they ought to descend in order to found the basis of future elevation. It has happened to me more than once, when taking opportunities of being useful to a young man of merit, that I have experienced opposition in taking him from his books and drawings, and placing a mallet and chisel, or a trowel in his hands, till, rendered confident by the solid knowledge which only experience can bestow, he was qualified to insist on the due performance of workmanship, and to judge of merit in the lower as well as the higher departments of a profession in which no kind or degree of practical knowledge is superfluous. *For this reason I ever congratulate myself upon the circumstances which compelled me to begin by working with my own hands.*'

" You will find indeed that not Telford alone, but that most of the men who responded to the demand that arose in the middle of the last century, for professional aid in the formation and construction of that class of works now distinguished as works of civil engineering, in default of skill and capacity on the part of the architects of the day, were men whose early education was that of the workshop;—they were *masons, miners*, and *millwrights*. Whilst the practical knowledge of Telford and Rennie—the mason and the millwright—exists in its effects upon those who had the advantage of working with and under those eminent hydraulic architects, the practice of civil engineering as at present constituted will continue,—but those who seek to engage in and follow it must qualify themselves by direct application to the sources from which it sprung, and upon which alone it can rest a continued existence. The man of science may be formed independently of the workshop—but it is through the workshop alone that the man of science can become what the men I have enumerated were; he may possess himself, in the office, and in the service as an assistant, of the established practitioner of the routine of business,—of the habit of using technical terms,—of repeating working and other drawings, and of using set phrases and forms in the composition of a specification;—he may learn to estimate and to describe the items of an estimate as they are usually described, and to attach prices to the items according to the established usage;—and having made these acquisitions he may consider himself fitted to practice as a civil engineer. He will feel himself competent to investigate any question that can arise in practice when the *data* are supplied.—but he will find that questions continually arise upon which no data are to be obtained; he will readily undertake to lay out and design any class of work within the range of engineering practice, but he will learn from the contractors as the work proceeds, that this cannot be done as he may appear to have intended,—that that will not do in this particular case, that such and such things are unnecessary, and such others essential, and when the works are completed he will have the mortification of finding that the variations made, and the alterations and additions effected have made his contract a dead letter. . . . . There are other cases, however, and they are already too frequent, in which conscious incompetence determines to be on the safe side, be the cost what it may, and works are overloaded with materials that they may be strong enough;—and thus again the employer is defrauded, for fraud it is if a man undertake a duty which he is not thoroughly qualified to perform."

Mr. Hosking then proceeded nearly as follows, giving an etymology of the designation of engineer, which has the appearance of novelty, and entering into details which we have not space to include in our mere abstract:—

" It may not be devoid of interest, and it may help to give a distinct perception of what the practice of civil engineering includes, if I trace the circumstances out of which it grew. Many of the works and operations now included in the practice of the civil engineer are of late origin themselves, and a large proportion of them were formerly within the practice of architecture, and was known, when distinguished at all, as hydraulic architecture. Modern fortifications, or fortifications having reference to ordnance, consist in a great degree of earthworks, and through the practice of forming them the different corps of military engineers became skilful in the disposition and working of earth,—in draining for the exclusion, and in forming conduits and sluices for the admission of water. As the advance of modern civilization required operations similar to those practised by the military engineers for protecting lands from rivers, and from the sea, by embankments,—for draining low lands,—for supplying towns, and for feeding canals with water, the peculiar designation of the military engineer and operator was adopted by the civil practitioner, who thus became what is known as the civil engineer. Throughout the continent of Europe the services of the architect had been still in requisition in aid of the military engineer, in directing the constructions for which he had occasion, and we thus find some of the finest works of many of the Italian architects from the 13th and 14th centuries down to the present time, on the gates of fortified places. In England, however, almost ever since the introduction of gunpowder, the fortification of towns and cities, fortunately, has not been necessary, and the British architect has had therefore no practice in connection with the military engineer. Hence, the almost total deficiency of architects in this country in hydraulic constructions, so that when a demand arose for works which imposed such constructions in connection with earthwork formations, the millwrights and masons, who had built the flood-gates and sluices with their wing and head walls, and had learnt to direct the formation of the earthworks from the Dutch embankers and drainers, were called upon to undertake them, and thus the hydraulic architect is found in conjunction with the formator or embanker and drainer, who brought to the profession thus compounded the designation of civil engineer.

" The practice of civil engineering and architecture is, therefore, strictly, the complete practice of architecture in its most extended sense; that of the former may be said to include formations and constructions influenced by, in connection with, or affected by, that powerful agent—water,—whilst, the separate practice of architecture is generally restricted to constructions not so exposed, and to constructions susceptible of, and subject to decoration. The architect who builds sewers and drains,—and it is within the practice of all architects to do so,—is in so far a civil engineer,—whilst the engineer who builds a bridge, or a viaduct, is in so far an architect, for although, according to the general definition that I have given, the founding of piers and abutments to a bridge over a river, or other water, would fall within the province of the engineer, the main constructions of a bridge, especially when of masonry, are within that of the architect."

" Roads as now made, and railways, are late additions to the practice of the civil engineer. Roads brought bridges with them, and railways have brought many other varieties of construction that can hardly be called hydraulic, for although their frequent connection with earthwork exposes them for the most part to the action of water, they are generally so situated as to demand the architectural dispositions which may be classed under the head of decoration. To be an accomplished civil engineer a man must, therefore, be a good architect in the ordinary acceptation of that term, as well as skilled in the sciences and arts of construction, far above what architects commonly are. Together with formations and hydraulic constructions the practice of civil engineering includes the application of machinery in the aid of commerce and of the useful arts. Hence, and because of the name applied to some of his productions, the manufacturer of engines and machinery, the mere machinist has been called an engineer. A machinist may certainly become a civil engineer, but the power of making a locomotive engine does not seem to form a better qualification for railway engineering, than that of carriage building does to constitute the builder an efficient roadmaker;—it is not the cannon-founder who is entrusted with the construction of fortified places and field works, but the engineer officer whose education and practice have fitted him for this more important service."

" In promising information and instruction that will be useful to you in the pursuit of your professions respectively, I must beg to be understood not to promise to qualify you here to practice as architects or as civil engineers. We offer you information whereby you may become qualified to avail yourselves more effectually of the practice of the engineer's or architect's office, and thereby to become *better* architects and *better* engineers, to your own confidence, comfort, and advantage, and for the advantage of society to whom your services will be hereafter offered, than you would have been without such instructions and information as we offer. The medical student comes here versed in pharmacy, and in the simpler surgical operations, and he finds his field of study and practice complete between the lecture and dissecting rooms of the college, and the wards and the operating theatre of the hospital, but to you, who come to us unskilled in carpentry and masonry, the pharmacy and surgery of your professions—we have the deficiency to supply, as well as to teach the science which those humbler arts aid you in applying, but *your* hospital must be walked in mud boots, and your operating theatre found on the stage of the carpenter, and on the scaffold of the mason and bricklayer. The young sailor may and should learn navigation on shore, and how to rig a ship and to reef and steer in harbour, but he must go to sea to become a sailor,—and the young architect or engineer, may and should, in like manner, acquire the theory, and learn, as far as may be, the practical arts of his intended profession, in a preliminary education, but he must place himself with the active practioner through whom he may have facilities for seeing works in progress, and opportunities of assisting to forward them, together with the means of acquiring the technicalities of practice, to become an efficient practitioner of architecture and engineering himself.

But why, I may be asked, if the practice of an office and the observation of actual works is essential after you have expended time and money here, why not go from school or college at once to a practical office? I answer, that without such preliminary education in science and the arts as that offered you here, the practice of an office will be in a great degree lost upon you; you may learn by rote but you will not know the meaning of the words—you may have opportunities of seeing works, but "seeing you will not see, and hearing you will not understand;" the characters may be clear, and the meaning of the words obvious, but to you they will be unknown, and therefore unintelligible.

I would say, then, acquire superiority over the merely practical man—the rule of thumb engineer by the attainment of sound scientific knowledge, in addition to the mere practical skill with which he tenders his services;—but do not depend upon scientific knowledge alone, if you propose to become civil engineers, and hope to gain your bread by the practice of civil engineering as a profession, for it may be truly said, paraphrasing the beautiful language of an inspired writer, you may have all learning and all science, but if you want this practical knowledge of which I speak, you will be but "as sounding brass or a tinkling cymbal."

SCHOOL OF DESIGN, LEICESTER SQUARE.

On Monday the 15th ult., a lecture on the application of perspective, being part of a course, was delivered by George Foggo, Esq., at the School of the Society for Promoting Practical Design, Saville House, Leicester Square, before a numerous and respectable audience of members of the society, artists, students, &c.

The lecturer commenced by urging the necessity of a knowledge of perspective in ornamental design; observing that however the students in that class might be inclined to undervalue such an acquirement, they could not nor did not make a drawing without availing themselves of it. So accustomed are we to see objects in perspective, that we are perpetually putting objects in perspective without being aware of it. The child newly born is destitute of this knowledge, but we cannot pass through life without acquiring it—we must perforce obtain a knowledge of the distance of objects, their relative positions, their size, their colour. There is not a human being who does not learn this—not an animal—we could not go through life without it. Whether in historical composition, or whether in architectural design, we are obliged to have recourse to perspective. The architect, after making his design, may think he has nothing to do with this science, but if he do not attend to it, he will soon find himself in serious difficulties. Suppose, for instance, he has designed a frieze; although it may look very well upon paper, yet, when it comes to be placed high up, and lighted in a particular way, he may find the effect very different from what he intended. From want of knowledge of this kind, lamentable errors occur; in buildings recently erected, ornaments are lighted with windows in such a way as to lose their effects; a delicate scroll is placed at such a distance as not to be seen, and bold ornaments brought too near. I am anxious, said the lecturer, that in drawing ornament we should not draw it as if it were a mere dead inanimate object, but should remember that taste is required for designing pure ornament. This may not suit those who are contented with copying, and think that they have done enough when they have reproduced a design from the French, or the German, or the Italian, or the Greek; but it is the right course—copying we always find limited, nature ever varying. We have heard much lately about copyright of all kinds, but I think a great deal more has been said than has been necessary; I am by no means disposed to admit that copyright can be derived from the mere act of copying the design of another, whether that design be French or Greek, one year old or a thousand. Copyright should have no right for merely copying others, but for original adaptations of natural objects. Composition requires originality and power of mind, without which the name is idle. The architect has irregular materials to bring into regular proportions; the designer of artistical compositions has the opposite course, to take fixed objects, and to place them in every allowable variety of attitude that is to be found in nature. Some imagine that great diversity of power is required for these two objects, that it takes very little power to make an architectural design, and much to produce a picture. I am not inclined, however, to allow this. Want of reference to nature is, in my opinion, the principal defect of our architects, the result of which is the greatest inconsistency. Thus, if we want a church, the architect will, without regard to propriety, take a Greek temple for his model, and so in an edifice where no sacrifice is allowed, devoted to a religion by which it is abolished, we shall find the sacrificial ornaments of another creed. If we are to have a theatre, the same temple is referred to, and then we get the sacrificial emblems again. There is no thought of propriety, though a building should be appropriate in its character to the object to which it is devoted, and mark the circumstances which have influenced its erection.

The architect having to do principally with straight lines in composition, has of necessity much difficulty to contend with, but he has other and greater difficulties; the want of having men of taste to judge of his productions causes inactivity on the part of the architect, and the result is that he contents himself with making a flaming copy from some antique building of reputation, which pleases the committee because it saves them the trouble of judging. His rival, with less knowledge of the world, labours hard to produce a good plan and an original elevation; his plan is never looked at, because it is not understood, and his elevation being placed by the side of those of his competitors, is outstared by them, and so he is discarded. By and bye the favoured design is carried into execution, and then, to the general disappointment, it is quite inapplicable. (The lecturer here proceeded to sketch the ground plan of a building, and show the modifications which would be required in the external effect by different arrangements of the interior.) When an architect has got over the impediments thrown in his way by the ground plan, he will, without a knowledge of perspective, find himself in serious difficulties in making his elevation. There will be a want of important parts, broken lines, intricacies in the external arrangements, so that the eye can never repose satisfactorily. Still a good plan is a great thing, and it is of much importance that the public should know what plans are, for every one may now be on a committee some day, and it is very essential that this point should be understood. The elevation may mislead, while the plan is the first thing, and when we have provided for the useful, we can afterwards see what sort of a fine frontage can be applied. Some of the cabinet-makers and upholsterers studying here must very frequently be applied to with regard to furniture, when they first send in a drawing of what is imperatively necessary, and then do what they can to ornament it afterwards. Sometimes, however, the contrary occurs; a pretty drawing is made, and when the article comes to be put up, it is found clumsy and useless. Nor do I hold that it requires much less talent to design furniture properly than to design a building—and, indeed, in many of our recently erected club-houses, the architects have themselves designed the furniture, plate, &c. Unfortunately, however, architects have little studied this department, and if they attempt it, there is a baldness in their works far from pleasing.

Architects have not often, more particularly in crowded cities, the choice of situation, but still it is in their own power to do something more than they do. There was, for instance, no necessity in Pall Mall to swamp the Travellers' Club by rearing next to it the Reform; had this been done by others, Barry would most probably have been offended, but people are not so offended at their own deeds as at those of their neighbours. Here, however, the example is given, and so, perhaps, some day we may have another larger, and the Reform Club itself overshadowed. The back of the Traveller's Club is not the less admirable, and it is much to be regretted that the architect had not combined the two buildings in one design. It is, in fact, a duty of architects to avail themselves of the position in which their building is to be placed; if, for instance, the space were next to a church, then, by making the new buildings, though not uniform, yet in some degree, correspond with those on the other side, the church might be brought into the composition, and so a better effect produced. Regular composition in architecture requires a centre and two wings; so if we see a bridge with four arches, the effect is unpleasant, though this is sometimes avoided by making the piers more prominent, but this again leads to another impropriety. The bridge, to be effective, must have three or five arches. The building, too, requires good thick flanks; this Wilkins forgot, and thus, in the National Gallery, we have the flanks getting thinner and thinner till they come to almost nothing. Solidity of effect is a thing imperative—the human mind requires bulk—it does not consider surface sufficient; if we see a surface, we like to know what is behind it, and particularly with regard to stone, for we always imagine the other front must be something similar. I may be reminded that, in the Gothic, there are exceptions and most beautiful ones, but these are exceptions only as between the uninstructed and the instructed—the instructed will see where strength is, and so be better satisfied with the effect produced. It is our duty to make our building as vast as possible with the materials we possess; if we do something great with small materials, money is saved; if great materials are frittered away in petty details, we have spent a vast deal to produce a little effect. It may be thought much better not done at all, unless the effect be produced at little expense. Two instances have been greatly extolled by our travellers; St. Peter's, at Rome, say they, is so vast and so beautifully proportioned, that we do not perceive its grandeur, and it is only when we come to examine some of the parts, that at last we are convinced. Another instance is the column in the Place Vendôme, at Paris, which is made after a barbarous Roman model—a column in Grecian proportion, is covered with a thick coat of bronze, and made gouty, just like the Duke of York's column in the Park. If the Napoleon column appears 80 feet high instead of 150, it certainly appears to me much better to have spent *half* the money to have produced a column which should have appeared 150 feet high. It is travellers only who see things of this kind, who stand openmouthed with astonishment that much money should be thrown away to produce nothing.

Architects very frequently complain of want of money, but with injustice, for it is by no means the amount of money, nor the vastness of the material at their disposal, on which the affair depends, particularly if money be exhausted on a number of small parts. No error is greater than to divide a thing into a number of small parts; if we want to know the effect, let us go into a mountainous country, and we shall go on from one mountain to another, and always find the object in the distance of the same comparative smallness. We see the distant peak with clouds lying about the sides, dividing it, and some covering it, some lying in streaks across it, but it does not appear high. We get to the top of another mountain, but a deep valley lies between, and it still does not appear high; we climb from crag to crag, and when we have got to the top we have an unbounded view, but we do not appreciate the immensity of the elevation, we feel rather delight than surprise. Had we seen a precipice, instead of 15 or 20,000, a thousand feet high, the effect would have been different. Many instances might be mentioned, but there is one place in the United States where the view is so terrific, that no courage can encounter it twice. Persons who wish to see this place go provided with guides, and secured with cords, and after looking down become senseless, and when asked always refuse to try it again. So different is it to see a simple elevation, or to see a thing frittered away bit by bit. This is not without its lesson in architecture; the Gothic architects knew it and profited by it. We see it if we look at the Gothic spires and towers with their tops wreathed with ornament; such compositions show that our ancestors understood this effect perfectly. Let us sketch a tower: we have here a great height, but in proportion to the bulk is the apparent elevation reduced; to remedy this, we must do as Barry is going to do at the New Houses of Parliament, we place simple turrets at the corners, sometimes of unequal size to produce picturesque effect. Looking up, the eye runs along this narrow line, and appreciates the full height of the object, at the same time that the bulk is also felt by this combination of parts. The composition of Gothic buildings requires great consideration, both of perspective and composition, as well as of appropriateness of character. If we construct a residence for a clergyman, we must make it comfortable, but at the same time we must give it a certain clerical character; but if we make a house for a country squire, we must not have anything clerical at all. In the Gothic cathedral immense length was required to provide for numerous processions with music, when the effect produced by them is overcoming. Great elevation was also necessary. We always see, therefore, in such buildings, one part of great length, and as the screen was not originally placed where it now is, but at the entrance, the view was surprising, for while we had figures six feet high close to us, in the distance they were reduced to insignificance. If we look at the means adopted to produce elevation, we shall see that, however numerous the divisions of the columns were to provide the strength required, the architects always took care to have some small fillets, which, being continuous from the bottom to the top, and there vanishing into nothing, give the mind a conception of vast and unlimited height. The contemplation of a cathedral of this kind appears, perhaps, much more elevated, and has a greater effect in raising the imagination than even a mountain itself.

I know nothing in architecture which contains more composition than Gothic architecture—the Greek temple of vast proportions perched on an isolated rock is simple and majestic—but the Gothic cathedral contains an interminable variety of applications from nature. Having said enough on composition in architecture, I may say that it is of no trifling importance to the historical or landscape painter—both will find excellent studies in Gothic architecture. In the combinations of the architect and the artist there is something more required than mere arrangement of parts, for though the Greek architect is limited to such as are symmetrical, the Gothic is not so strictly limited, and the historical painter is called upon for no symmetry at all, yet composition, to have a lasting effect, must operate on the mind, as much as on the eye. We therefore require a combination of poetical feeling with symmetrical arrangement, for to the architect fine feeling belongs as much as to the artist, and although an architect may not have it in his power to make a cathedral, yet he can show much of the same qualifications in a small building, in furniture and hangings, or in plate for a dining room. Plate is generally ordered at the silversmiths to be made after the pattern of that of Mr. So and So, who had it presented to him for services in the East Indies, but as Mrs. So and So, who has never been in India, must have her plate like that of the other individual, it may be made as similar as possible in shape, and yet far from it in detail, and analogous to the condition of the lady. A case in point occurred to me. I was asked to design a monument for a person who was of a very peculiar character, of good circumstances, had been in trade, and led a very even samely life. The deceased having a relation who had died at the head of his regiment, a monument was desired for him like his cousin's. Here was the contrast, a quiet merchant and a dashing colonel, however I did what I could, and I do hope the thing will not be found fault with. If we have a piece of plate to design, we need not attend most to the weight of the material, but with lighter materials we may endeavour to give an appearance of quantity, making the ornaments bold, and cutting away metal and material in different places—although, by the by, persons do inquire into the weight of metal. I have known this to be the case with Committees of the House of Commons, where silver has been preferred to bronze, because it would make a difference of 150*l.* in the value of the material, though the bronze would have cost more in the end, as the cost of the chasing was great. There are several things stand much in the way of good composition—want of a fair protection for copyright, and want of judgment in the public. In the many competitions which are advertised every day, the paltry premium offered for the design may be a hundred pounds, while the profit on the work to be executed may perhaps be thousands. There is a third difficulty, and that is want of power in artists, from the want of fair competition, producing deficiency of high intellect, for those who have the power know better than to exert it on such occasions, they can trust to other ways for making money.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Feb. 8.—Edward Blore, V.P. in the Chair.

Messrs. G. A. Burn and J. J. Cole were elected as Associates.

Among the donations was a copy of Mr. Hay's elegant work entitled Illustrations of Cairo, presented by Mr. Greenough, and Mr. Scoles exhibited an interesting drawing by the late Mr. Bondini of the Cathedral of St. Peter's at Rome, and St. Paul's, London.

The construction of the stone arch, commonly called the stone beam, which exists between the towers of Lincoln Cathedral, having been discussed at a previous meeting of the Institute without any satisfactory results, from the paucity of data which existed in regard to this curious work of science, Mr. Nicholson, Fellow of the Institute, and resident architect at Lincoln, forwarded the following particulars. The arch is at a height of 80 feet from the pavement, immediately over the junction of the vaulting between the towers and the vaulting of the nave; its abutments are thus formed by the eastern walls of the two towers. The arch consists of 23 stones of unequal lengths; the width of the extrados is barely 1 ft. 9¾ in., the thickness of the arch is uniform throughout, 11 inches. The span measured horizontally is 27 ft. 11 in. between its *apparent* abutments, but the arch probably penetrates some more recent casing of the tower walls, so that probably the *actual* horizontal span equals 30 ft. The southern abutment is 12½ inches higher than the northern. This arch has hitherto been considered the segment of an arch; but the observations of Mr. Nicholson led him to the conclusion, that it is a pointed one, each half arch being struck with radii of different lengths, an inequality arising probably from unequal settlement. It is constructed of stone from the Lincoln quarries, the exposed surfaces being wrought with the toothed chisel in a careless manner. The joints are ill formed, and have a mass of mortar full half an inch thick within them. The arch vibrates perceptibly, and Mr. Nicholson is of opinion that the practice of visitors jumping upon it in order to produce this vibration, may eventually lead to very lamentable results. Mr. Papworth suggested that very probably the arch was constructed by the masons at the time to serve as a fixed mark, by which to test the accuracy of the vaulting of the nave, particularly in the groining stages. But Mr. Nicholson considered this ingenious hypothesis hardly admissible, as the four walls themselves afforded a solid datum by which to control the several levels of the vaultings.

Mr. Poynter read some admirable practical observations on the construction of observatories, with which we hope to furnish our readers at full length in some early number.

Feb. 22.—J. Kay, V. P. in the Chair.

Mr. G. Godwin was admitted as Fellow, and Messrs. Wood and Clarke were elected as Associates.

A volume of exquisite drawings by S. Burchell, Esq., of the details of Prior Birde's chantry in Bath Abbey, and ten guineas from T. L. Donaldson, Esq., secretary for foreign correspondence, were announced among the donations, and two numbers of a very well executed German work on Gothic architecture, now publishing at Nuremburg, were presented by Messrs. Black & Armstrong, booksellers, of London. This publication is remarkable for the judgment with which the subjects are selected, and the tasteful effect with which they are engraved.

A letter was read from M. Vaudoyer, corresponding member, communicating various particulars connected with architecture of recent occurrence at Paris, particularly in regard to Marochetti's monument to Napoleon, which consists of an enormous sphere on a square base, surmounted by an equestrian statue of the emperor with his frock coat and little hat. The style of the monument, and the employment of a foreigner on such a work, has excited much displeasure among the artists of Paris. M. Vaudoyer described a new species of competition, which took place in the time of Louis XVI., who was anxious to complete, in a becoming manner, the Palace of Versailles, then unfinished. Upon the recommendation of Monsieur Le Comte d'Aigmillers, five of the most celebrated architects of the period were introduced to the king, who explained to them his views and wishes, and called upon them to assist him by their talents in rendering the Palace of Versailles worthy the nation. He assigned to each of them 12,000 francs as a complimentary sum, and 5000 francs to cover expences, and gave them 8 months to prepare their designs. The intention was, when Messrs. Chalgrin, Heurtier, Antoine, Peyre Jun. and Paris, the architects chosen, had completed their designs to have them exhibited to the public, and then examined by a jury consisting of the candidates themselves and four other architects. This committee were to make individual reports on each, and a general report on the whole, and to select the two best for recommendation to the King, who was to be at liberty to choose any parts of the other designs, so as if expedient to form a new one composed of the chief beauties in the whole number, and which was to be carried into execution by one or both of the two selected by the jury. The designs were made and paid for, but never exhibited; for the storms of the revolutionary period began to cloud the horizon of the arts, and the scheme, so admirably projected, had no positive results. But M. Peyre published his, in his volume of designs, 1818.

Mr. Scoles, fellow, read an analysis of Col. Howard Vyse's splendid work *on the Pyramids of Egypt.* The great pyramid covers rather more than 13 acres, each side of the square being 764 ft., and the height is 480 ft. 9 in. It is generally supposed that the area of Lincoln's Inn Fields equals that of the Great Pyramid. But it appears that one side of that square between the houses, being 831 ft. and the other 625 ft. 6 in., its area is less than that of the Great Pyramid by about 64,000 square feet. The height of St. Paul's is 365 ft. or 115 ft. 9 in. less than the Egyptian building. Mr. Scoles then minutely described the mode of construction, the arrangement of the chambers and galleries, the objects found, and the chronological history of the erection and events connected with these huge wonders of antique art, tracing it down to the discoveries of the gallant author, and for which we must refer the reader to the work itself. Mr. Perring, a civil engineer, took the dimensions of these edifices, and Mr. Arrundale had the management of the volume, and the preparation of the drawings confided to him by the munificent author. Mr Scoles' description, which was rendered doubly valuable from his own personal examination of these monuments, was listened to with much attention, and gave rise to some curious remarks by Mr. Hamilton and other members. For our part, we cannot help imagining that there still remain unexplored chambers in these masses of construction, and that discoveries may still repay the patient investigation of future enterprising travellers.

ROYAL INSTITUTE OF ARCHITECTS OF IRELAND.

ADDRESS TO SIR RICHARD MORRISON.

In a recent number of the *Mail* we noticed with pride and satisfaction the honour so deservedly conferred on our eminent countryman, Sir Richard Morrison, by the representative of our most gracious Sovereign. It is no small addition to our pleasure to lay before our readers, in this day's publication, the honourable testimony of the satisfaction which that act of royal munificence has given to a body of gentlemen who, of all others, are best qualified to appreciate the value of the distinction, and to estimate the merits of the individual who has been thus selected for the rewards of her Majesty's favours.

But it is not alone as a favour to Sir Richard Morrison that this honour is to be considered. It is an honour conferred, in his person, on the noble art which, with such credit to himself, and benefit to the public, he has successfully cultivated. The honour due to Sir Richard for his individual merits, was due also to the profession of which he is and has been a distinguished member, and which he has been mainly instrumental in raising to its proper station of dignity and usefulness in this country, by concentrating its genius and its energy in the association from which this address emanates. It has ever been the policy and the practice of the illustrious house, of which her Majesty is no degenerate descendant, to encourage the fine arts by such honours on their professors as the State can confer; and, whilst we refer with pleasure to the distinctions conveyed, in their professional capacity, on a Reynolds and Chantrey, it gives us no less pride to find our countrymen—a Shee and a Morrison—equally honoured by the distinguishing approval of the Sovereign.

In this instance, at least, justice to the individual has been "justice to Ireland," honour to Sir Richard Morrison, an honour to his profession.

The address was presented to Sir Richard on the 5th ult., at his residence in Mount Street, by a distinguished deputation from the body, and read by John Papworth, Esq., the honorary secretary, after the following brief, but well conceived prefatory observations:—

"Sir Richard Morrison, the duty which devolves upon me this day, as secretary to the Royal Institute of the Architects of Ireland, I feel to be one of an extremely important and interesting nature, whether we consider it with reference to our own profession, or to the fine arts in Ireland. I am highly honoured to be the medium through which the sentiments of our institution are to be conveyed to you, on the occasion of that honourable distinction which has been conferred on you. I am aware my associates around me participate in the feelings of pleasure which I entertain at this moment. It is unnecessary for me, Sir, to dwell upon the circumstance which has brought us together this day, as it is fully expressed in the address which I shall now have the honour to read."—*Dublin Mail.*

SOCIETY OF ARTS FOR SCOTLAND.

January 25.—Dr. Fyfe, President, in the Chair.

Professor Forbes gave, at the request of the President and Council, an exposition of *The Doctrine of the Polarization of Heat.* On this evening he proposed to give an account of the instrumental measurement of temperature. This introduction was illustrated by examples of the various instruments in use, from the air thermometer of Sanctorius, to the delicate thermomultipliers of Nobili and Melloni. In the course of this historical account, he adverted to a recent ingenious improvement of the common flint thermometer, by M. Viiltz, and which, he believed was not yet published: this improvement consists in sinking the tube to the depth of two-thirds of its diameter into the material of the scale; by which arrangement the parallax in one direction is compensated by the refraction in another, so that, in all positions of the eye, the degree read off is the same.

A description of *A Self Inking Press* was read, illustrated by drawings and working model, by Mr. John Napier, which was remitted to a committee; and afterwards a short notice of the completion of the printing of the whole Bible in relief for the use of the blind, by John Alston, Esq., Rosemount (Glasgow; for which he was congratulated by the Society.

February 8.—Shirreff L'Amy, V. P., in the Chair.

The President read an interesting account of a series of extensive experiments *On the Evaporating Power of various kinds of Coal,* (including the anthracite), as obtained by combustion in furnaces. The general result of these experiments seemed to be that the practical heating power of all coals is almost exactly in proportion to the quantity of fixed carbon; there appearing to be no heat whatever procured from the volatile matter of the coal. This circumstance Dr. Fyfe accounted for by supposing that the hydrogen and volatilized carbon abstract, in passing to the gaseous state, as much heat as they develop during combustion.

Mr. Sang drew the attention of the Society to an erroneous deduction drawn by the late Capt. Henry Kater, from his experiments on *the flexure of bars.* Capt. Kater had observed that the elongation of the distance between two marks on the surface of a bar when the bar is supported at the middle, is but one-half of the elongation caused by supporting the same bar at the two ends, the same reduction on account of curvature having been allowed for in both cases. And he had thence concluded that the neutral plane is not, as is usually supposed, in the middle of the thickness of the bar, but only at one-third of that thickness from the convex side. Mr. Sang showed that this result would imply that bodies resist distention with eight times the energy with which they resist compression; and he pointed out that the disparity observed by Capt. Kater is due to the difference of curvature in the two states of the bar, and that that disparity agrees with the deduction of the ordinary theory of flexure. He also pointed out some errors in Capt. Kater's methods of computation and experimenting which seemed to him to destroy all confidence in any of that philosopher's experimental results.

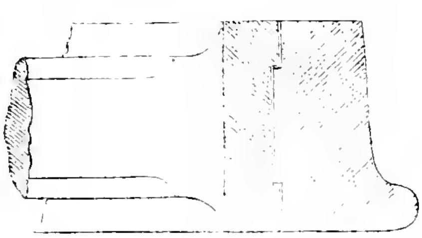
Royal Victoria Gallery, Manchester.—A long discussion has taken place at this institution upon Mr. Palmer's plan for the improvement of the Mersey and Irwell Navigation. In this discussion Mr. Radford, Mr. Hawkshaw, Mr. Buck and other eminent engineers took part: it is, however, reported at too great length to allow us to notice it this month. We are glad to see so much interest taken in engineering in that part of the country, and we should like to see Institutes at Manchester and Newcastle. The architects have already an Institute at Manchester, and the engineers should not be outdone.

Royal Scotch Academy. (From an Edinburgh Correspondent.)—This exhibition is now open, and it is an admirable one; the progress which is being made in art in this country is very satisfactory. There are few architectural designs, which is not to be wondered at, as the accommodation for drawings is miserable, every thing being sacrificed for oil paintings, the veriest daub in oil having a better place than a chef d'oeuvre in water colour. We are even worse off in this respect than you are in London, inasmuch as the little room given to our architecture and water colours is further curtailed by the introduction of the *sculpture!* the specimens of which, with the exception of the works, by members or associates of our Academy, are in most instances below criticism. Our Associations or "Art Unions" are reported to have larger funds this year than last, so that 8 or 9000 pounds will probably be spent in art this year. The last sum must be nearer the truth if general report may be depended on.

EXTRAORDINARY EXPERIMENT.

An experiment was tried on Saturday, 20th ult., of one of the inventions to which we alluded last autumn, which a friend on whom we have reliance had an opportunity of witnessing. The trial took place in the grounds of Mr. Boyd, in the county of Essex, a few miles from town, in the presence of Sir Robert Peel, Sir George Murray, Sir Henry Hardinge, Sir Francis Burdett, Lord Ingestrie, Colonel Gurwood, Captain Britten, Captain Webster, and some other gentlemen, who all appeared very much astonished at what they saw. By the kindness of the inventor our informant occupied a position that enabled him to command a view of all that took place. A boat 23 feet long and 7 broad was placed in a large sheet of water, the boat had been the day before filled in with solid timber, four-and-a-half feet in depth, crossed in every direction, and clamped together with eight inch spike nails. This filling in was made under the inspection of Captain Britten, who stated the fact to the distinguished gentlemen we have mentioned, and also that the inventor never went near the workmen employed, that no suspicion might be entertained of any combustible materials being lodged in the hold of the vessel. Several of the gentlemen were on Saturday rowed in a punt to the vessel, and examined for themselves, so that every doubt might be removed as to the cause of destruction being external, and not from the springing of any mine. When the different parties had taken up their positions, on a signal from the inventor, the boat was set in motion, and struck just abaft her starboard bow, and instantaneously scattered into a thousand fragments. At the moment of collision the water parted, and presented to the eye of our informant the appearance of a huge bowl, while upon its troubled surface he noticed a coruscation precisely resembling forked lightning. A column of water was lifted up in the air like a huge fountain, from which were projected upwards for many hundred feet the shattered fragments of the vessel, which fell many of them several hundred yards' distance in the adjacent fields. Our informant examined many pieces, and found the huge nails snapped like carrots: the mast looked like a tree riven by lightning, and never before, as he assures us, has he witnessed so sudden and complete a destruction, though he has seen shell and rocket practice on the largest scale. Such seemed to be the unanimous opinion of all present. How this mighty effect was produced was of course not disclosed to so numerous a party, but two naval officers present were perfectly aware of the mode of operation, and the inventor offered to go into details confidentially with one or two of the distinguished officers present. In answer to a question from Sir Henry Hardinge, the inventor stated that without a battering train he could transport on a mule's back the means of destroying the strongest fortress in Europe. No doubt this is very startling, but, hearing what we have, we cannot pronounce it impossible; and as in every particular the inventor has done what he has undertaken to accomplish, it is only fair to give him credit for the performance of more than has yet been disclosed. The existence of these tremendous powers is placed beyond all doubt, and the inventor asserts them to be completly under his control, which, from what our informant has had an opportunity of observing, he believes to be really the case. The instrument that wrought so terrible an effect on Saturday, lifting into the air a boat weighing two and a half tons, and filled in with five and a half tons of solid timber, and displacing at least fourteen or fifteen tons of water was only 18 lb. weight. Our informant has handled it and kicked it round a room when charged with its deadly contents, so portable and at the same time so safe is it—a point of vast importance, when we remember the daily accidents that are occurring from the detonating shells now used in our service. At Acre most of those employed burst before they reached their object, and they are liable to explode when rolling about a ship's deck, as was proved by the fatal accidents on board Her Majesty's ship Medea, off Alexandria, and the Excellent, at Portsmouth, and are dangerous to carry in a common ammunition cart on a rough road. Whether Lord Melbourne will condescend to examine into this matter, and secure these mighty powers for this country, or permit them to pass into the hands of our enemies, is more than we can venture to predict, but about which we cannot think England will remain indifferent. The inventor has requested us publicly to return his thanks to Mr. Boyd for his great kindness in permitting him the use of his grounds not only on this but on several occasions.—*Times.*

IMPROVED TIRE OF A RAILWAY WHEEL.



ANNEXED is a small sketch of a section of the tire of a railway wheel, showing a new mode of fixing the outer tire.

Many accidents, particularly to the machinery of locomotive engines, have occurred from the bolts (which are used in general, but in my improvement are not *necessary*) breaking, and allowing the tire to work off laterally, and to come in contact with the working gear. The improvement consists in having a groove turned out of the wheel, and a corresponding tongue on the inside of the tire, as shown in the sketch, which prevents the possibility of the tire coming off, but by its breaking, a contingency which but seldom happens.

H. W.

Manchester, Feb. 4th, 1841. *Railway Times.*

HISTORY OF THE LONDON AND BIRMINGHAM RAILWAY BY THOMAS ROSCOE,

ASSISTED IN THE HISTORICAL DETAILS BY PETER LECOUNT.

SIR—In your last number a communication appears from Mr. Lecount, animadverting on the use of his name in the above work, and also on the publishers for not paying him for his services. Having had the entire direction of the publication of this book, I feel it necessary to say that these statements are grossly incorrect, and that I am ready to prove this when called upon.

Mr. Lecount says "after page 32 I had nothing whatever to do with it, and my name being connected with it is a perfect hoax upon the public." So far from this being correct, I can produce scores of pages of Mr. Lecount's manuscript which are printed in various parts of the volume! It is extremely unpleasant to bring forward the names of gentlemen, and I will here merely remark, that the manner in which his name is printed on the title page of the volume, was agreed to by himself, in my presence, at the suggestion of his solicitor at Birmingham! Indeed if it were improperly used, an injunction could readily be obtained to restrain such an imposition on the public—but Mr. Lecount finds it easier to write scurrilous remarks, than establish that which has no foundation in truth.

By implication he charges the publishers with breach of agreement, wilfully mis-stating facts. He says, "what I furnished for that work although done under a written agreement, has never got me a sight of sixpence of the publisher's money." If such were in reality the case, Mr. Lecount would not be long in claiming his right. I deny, in unqualified terms, any treatment of Mr. L. otherwise than the most honourable. For what services he rendered, he was remunerated by having a pamphlet of about 100 pages printed, which was afterwards "wasted," a single copy only being kept to prove the fact of its having been printed; and I have now before me, in Mr. Lecount's hand writing, a memorandum of the cancelling of the original agreement which was for a pecuniary consideration.

I am, Sir, your obedient servant,

WAREING WEBB.

Castle Street, Liverpool,
February 18, 1841.

ERRORS IN SCIENTIFIC BOOKS.

SIR—It is a little surprising that a few of the most gross and palpable errors as represented in some of the Plates, both in the old and new editions of "*Tredgold on the Steam Engine,*" should have remained so long unnoticed, particularly in Europe, where so very many skilful and scientific mechanics are continually poring over works in every department of science.

The first and only error, I shall *now* draw your attention to, is on plate No. 11, where, in the figure of a steam engine pumping water from a mine, the pump rod is connected with the piston rod *i*, *h*, to produce a parallel motion in both it and the pump rod, which exhibits a profound ignorance of mechanics, on the very face of it, (as there delineated) for though the piston rod will move parallel, the lifting pump rod at the other end of the beam will not.

I have heard of a London waiter getting a quart of wine into a pint decanter, but never heard of the diagonal of a square (or of a parallelogram) being crammed into either diameter of it. I have heard also of a man who affirmed *that nothing was impossible, and that he could bite his own ear off;* but after repeated contortions of the head and other attempts and trials, he gave it up: observing, however, that he *knew it could be done with a sudden jerk.* Perhaps a diagonal can be crammed into the square, as represented in the figure alluded to, in Europe, but to us ignorant folks in the Western World it looks rather "*slanting-dicular,*" makes us rather sceptical, and indeed seems impossible to accomplish, even with a *sudden jerk:* but, like our inquisitive neighbours, the Yankees, if it *can be done,* we are "*kind o' curious*" to know *how.*

As books of science are generally published to instruct the unlearned or uninitiated, it would be as well to have the figure 5, on Plate X (A) *engraved so as to be understood,* because as there represented, it now requires a person who already understands his business, to understand how to construct the parallel motion *as there represented.* The same figure is repeated in the following plate, No. X (B).

If the insertion of this little inquiry is not inconsistent with your sense of duty to the public, please to notice it in your useful publication, and you may perhaps hear again from,

Your very obedient servant,

ROBERT RATIONAL.

British North America,
January 20, 1841.

REVIEWS.

Papers on Subjects connected with the Duties of the Corps of Royal Engineers. Vol. IV. London: Weale, 1840.

We mentioned in our last our favourable impressions as to the manner in which the character of this interesting work is maintained, and it gives us pleasure this month also to bear further testimony towards it.

The volume is appropriately preceded by a memoir of the professional life of the late Thomas Drummond, from the pen of Captain

Larcom, which, restricted as it necessarily is, still shows enough to enable us to appreciate the character of that amiable man.

The first, second, sixth and seventh papers are on subjects purely military, which prevents us, on the present occasion, from making any comment upon them.

The third paper, by Lieut. Nelson, R.E., is on the important subject of shot furnaces, a question in the consideration of which the construction of iron steam vessels should also enter. In this paper we are glad to see an acknowledgment of the valuable suggestions of Sir John Guest and Mr. Evans.

Lieut. Caffin's description of a new steam apparatus for drying gunpowder, shows that he has introduced an important improvement, which we trust will be adopted by the authorities.

The memoranda on blasting rock, by Major General Sir J. F. Burgoyne, form a work, and a most valuable one, in themselves: we cordially recommend them to the attention of our engineering readers of every department.

Major Harry Jones's paper, the eighth, gives an account of the well in Fort Regent, Jersey, a work of great difficulty and great success. Major Jones also gives his personal testimony to having witnessed the successful operation of the water finders with the *baguette divinatoire*. It is curious, but we do not know what to say to it.

Captain Brandreth's report on the Island of Ascension is valuable and interesting, but does not fall within the scope of our observations.

The tenth paper is by Major Bolton, R. E., and is descriptive of the dam constructed across the waste channel at Long Island, on the Rideau Canal. To this we may afterwards have occasion to refer.

Lieutenant Nelson has contributed a series of notes which he calls engineering details, a memoir which must be useful, both as an example and a lesson to the younger members of his corps.

The description of the New Victualling Establishment at Devonport bears ample testimony to the ability of the two Rennies, under whose direction many of the works have been executed. It will be seen, by other examples, that the civil engineer has full attention paid to him in this work.

Mr. Howlett, the chief draughtsman of the Ordnance, describes an ingenious plan of his for connecting a locomotive engine and tender to a passenger train, in which we only see one difficulty—how it would work on sharp curves.

Lieut. Denison, the able editor, is author of the fourteenth paper, on a new weigh bridge, lately erected at Woolwich Dockyard, and also of the next, containing an account of another new work in the same establishment, a single coffer-dam.

The sixteenth and seventeenth papers on injecting cement into leaky joints of masonry, and on the employment of sand for foundations, are translations from the French.

The eighteenth paper is on the rolling bridge at Fort Regent, Jersey.

The nineteenth paper brings us again to a contribution of the editor, describing the mode adopted for restoring the roof of Woolwich Dockyard Chapel, on the failure of the principals.

The twentieth paper is on the wharf cranes made by the Butterley Company, communicated by Joseph Glynn, Esq., F. R. S., and the twenty-first on Mr. Woodhouse's cast iron bridge over the River Trent, at Sawley, on the Midland Counties Railway.

Reports, Specifications and Estimates of Public Works of the United States of America. Edited by W. STRICKLAND, Architect, C. E.: EDWARD H. GILL, C. E.; and H. R. CAMPBELL, C. E. London: John Weale, 1841.

When the "Public Works of England" first appeared, we expressed our approbation of the superior manner in which Mr. Weale had brought out that valuable work, an opinion which was fully borne out by the countenance of the public, and the satisfaction of the profession. It is at once a proof and a result of the success of Mr. Weale's exertions, that our Transatlantic brethren have entrusted to his care a similar volume on the Public Works of America. It affords us double pleasure to see that they have commenced so well, and that they have taken such an effective step to do justice to their works. The present is a companion to the former work, and is fully equal to it, it shows the same careful selection of subjects, the same fulness of details, and the same splendour of execution. We have no doubt of its success with the profession, for every exertion has been made to deserve it, and it has our heartiest wishes, not less for its intrinsic merits than for the good it is calculated to do the profession. We know nothing better adapted to promote professional studies, and to elevate the character of such pursuits among the public, than the productions of works like these, which are the best monument to the old practitioner, and the best lesson to the beginner. This, we are sure, is but part of a series, for the success of the result we trust will embolden Mr. Weale to give us also the Public Works of the Continent, and thus lay the foundation of a museum of practical information, to which every department of the profession may have recourse.

We shall now proceed to detail the contents of the first two parts of the work before us. The first 13 plates represent the Philadelphia Gas Works, constructed in 1835, under the direction of Mr. Merrick: the following extracts will show their extent:

> The works are laid out in eight distinct sections of ten "benches," or thirty retorts each, making an aggregate of two hundred and forty retorts. Each bench yields upon an average 10,000 cubic feet of gas daily, or, when in full action, an aggregate of 800,000 feet.
>
> To each section is a distinct washer, purifier, condenser, and station meter. The two retort-houses are each 200 feet long and 50 feet wide, located in the centre of the square, having between them a passage of 40 feet, which is excavated as a cellar and floored over water-tight. This passage and the arched cellars under the retort-houses serve as coal stores.
>
> Each retort-house contains one stack and four sections of retort benches, built back to back down the centre of the building on each side of the chimney. The apparatus for cleansing the gas is located to the north and south of each retort-house respectively. Two sections of retort benches are now completed and in action, and a third is now in the course of erection.
>
> The retorts are the broad or York D's, 20 inches by 7½ feet in the clear, set upon an original plan.
>
> The gas is washed in two waters through washers of simple construction, with valves so arranged as to use either as the first, the most pure water being used as the second. The condensers are of ordinary construction, modified so as to enlarge the receptacle for the residuum at the base of the columns. The purifiers are constructed for dry lime, with a hydraulic seal for shitting, by which the use of valves in the purifying house is avoided.
>
> After passing the meters, the gas from all the sections mingles in the gasometers or gas-holders.

Appended to the description of the Gas Works there are some valuable reports upon the construction of the works, the cost of making gas, &c.

The next plate is a drawing of a Reservoir Dam across the Swatara. Plates 15 and 16 exhibit the construction of the Twin Locks on the Schuylkill Canal at Plymouth (U. S.) Plates 17 & 18 the bay of Delaware and the Breakwater in progress; the following extract from the report describes its magnitude: after examining into the construction of the Breakwaters at Cherbourg and Plymouth, the report recommends:

> The inward slope at 45°, the top 30 feet in breadth, and at 5⅓ feet above the highest spring-tide; the outward slope of 39 feet altitude, and of 105¾ feet base; both dimensions measured in relation to a horizontal plane passing by a point taken at 27 feet below the lowest spring-tide. The base bears to the altitude nearly the same ratio as similar lines in the profiles of Plymouth and Cherbourg Breakwaters.
>
> The part comprehended between the sea bottom and a horizontal plane 6 feet below the lowest spring-tide, the mass to be formed of stones weighing from ¼ to 2 tons, those of 2 tons comprising three-fourths of the mass. The slopes of this part to be covered with blocks weighing from 2 to 3 tons.
>
> For the part comprised between the latter horizontal plane and the lowest spring-tide, the mass to be composed of stones weighing from ½ to 2½ tons; those of 1½ to 2½ tons forming three-fourths of the mass. The slope of this part to be protected by blocks weighing 3 tons.
>
> For the part comprehended between the lowest and highest spring-tide, the mass to be formed of blocks weighing from 4 to 5 tons, and laid as regularly as practicable. The slopes of this part to be formed of the largest blocks and to be laid headwise.
>
> The estimate submitted by the Board was as follows:—The profile of the work rests on a bottom of $29\frac{1}{10}$ feet, on an average, below the lowest spring-tide, and has a superficies of 535.472 square yards; which, being multiplied by 1700 yards (the whole length of the work), gives for the capacity of the mass $910{,}302\frac{4}{10}$ cubic yards.

Plates 19 to 24 exhibit the construction of the Philadelphia Water Works, the following description will give an idea of their extent:—

> It has been from the commencement determined, for the present, to erect only three wheels and pumps, which are now completed, (there are now six), and with them the most important part of the duty of the Committee. The first of the wheels is 15 feet diameter and 15 feet long, working under 1 foot head and 7 feet fall. This was put in operation on the 1st of July, 1822, and it raises 1¼ million gallons of water to the reservoir in twenty-four hours, with a stroke of the pump of 4½ feet, a diameter of 16 inches, and the wheel making 11½ revolutions in a minute. The second wheel was put in operation on the 14th of September, 1822, and is the same length as the first, and 16 feet diameter; it works under 1 foot head and 7½ feet fall, making 13 revo-

lutions in a minute, with a 4½ feet stroke of the pump, and raising 1¼ million gallons in twenty-four hours. The third wheel, which went into operation on the 24th of December, 1822, is of the same size as the second, and works under the same head and fall, making 13 revolutions in a minute, with a 5 feet stroke of the pump, and raising 1¼ million gallons in twenty-four hours. It is not doubted that the second wheel can be made to raise an equal quantity; thus making the whole supply upwards of 4,000,000 gallons in twenty-four hours.

The wheels are formed of wood, and put together with great strength. The shafts are of iron, weighing about 5 tons each. The great size and weight of the wheel give it a momentum which adds greatly to the regularity of its motion, so necessary to preserve the pumps from injury under so heavy a head as they are required to work, which is a weight of 7900 lb.; the height 92 feet.

The following statement exhibits the extent of the works, the number of tenants supplied, the quantity of water daily distributed, and the amount of revenue for the years 1823 (at which time the city only was supplied with water) and 1837 respectively. In 1823 the three wheels and pumps were in operation, 6½ miles of iron pipes were laid, 4,844 tenants were supplied with 1,616,160 gallons of water daily, and the revenue was 26,191·05 dollars per annum. In 1837 six wheels and pumps are in operation, 98¾ miles of iron pipes are laid, 19,678 tenants are supplied with 3,122,164 gallons of water daily, and the revenue is 106,132·37 dollars.

Plates 25 to 40 contain drawings of Dams and Locks, and Aqueducts of various canals on the James River.

The reports and specifications, which are published in a separate work, are drawn up with considerable care, and show that the profession in America are well acquainted with the practical department of civil engineering.

Railway Transit: a Letter to the President of the Board of Trade. By Francis Roubiliac Conder, C.E. London: Weale, 1841.

In this pamphlet Mr. Conder has gone into the consideration of almost every detail connected with the working of a railway, illustrating the subject by many ingenious and practical suggestions. On most points we agree with Mr. Conder, although we must reserve our opinion as to some other of his suggestions. To the profession this pamphlet will be of great interest, as it advocates their cause with ability and justice.

A Manual of Logarithms and Practical Mathematics. By James Trotter. Edinburgh: Oliver & Boyd, 1841.

This work is from the pen of one of the tutors in the Scotch Naval and Military Academy at Edinburgh, and fully answers to its title. It is one of the best and cheapest manuals with which we are acquainted.

The Year Book of Facts in Science and Art for 1840. By the late Editor of the "Arcana of Science." London: Tilt, 1841.

We, in common with the scientific and professional press who contribute to the Year Book of Facts, may almost be considered as interested while speaking in favour of a work to which our own columns contribute; we are therefore obliged to leave it to the judgment of the public, by calling upon them to purchase and examine it for themselves. We cannot, however, refrain from saying that it is a most valuable compilation, indispensable to the student and man of science.

Gandy and Baud's Windsor Castle. London; Williams.

A third part has appeared of this splendid work, which we lately noticed. It contains a number of valuable and interesting engravings, so that the present subscribers have every reason to be gratified with the exertions of the editors, which we have no doubt will be farther successful in ensuring for it an extensive circulation.

Description of a new Quart and Bushel Measure, by T. N. Parker, Esq., M.A., is a pamphlet on a new system of measures. Mr. Parker proposes that the gallon shall contain 256 cubic inches, so as to give greater facilities in calculation.

A new coloured lithograph of *Menai Bridge* by Mr. Ganci, has appeared—we recommend it to the attention of our readers.

Tyas's National Map of England.—We have before us a proof of No. 11 of this cheap and excellent map, which for clearness of execution, and accuracy, we believe to be superior to any map of its scale, extant, it shows nearly the whole of Sussex, with a large portion of Kent and Surrey. It is so arranged that every sheet is perfect in itself, or any number of sheets may be joined together.

A new edition will shortly appear of Peckston's Practical Treatise on Gas, with numerous plates, corrected and adapted to the present improved state of the manufacture.

NEW IMPROVEMENTS IN THE DAGUERREOTYPE.

On the 4th of January, at the sitting of the Institute, M. Arago announced that M. Daguerre had discovered the means of fixing the Daguerreotype pictures in the wonderful short space of half a second, or in other words instantaneously. This quite unexpected result will henceforward enable the Daguerreotype operator to obtain the representation of living and moving objects, of all which animate a picture. Our streets, squares, bridges and rivers, will not be as before, represented in the middle of the day plunged into a deadly solitude, but they will show us in reality all the animation which gives interest to a picture. The admirers of the Daguerreotype, and they are numerous among the well educated part of the community, are eagerly awaiting the disclosure of the important improvements of M. Daguerre, and we are sorry to hear that the ingenious inventor will not be able to bring his improvements before the public for a few months to come.

We understand that the improvements consist only in shortening the time of the operation, and that the effect produced will not be better than before. In fact we have with infinite gratification admired the specimens obtained by the original plan, which are exhibited by Messrs. Claudet and Houghton, in their numerous and beautiful collection, and we cannot conceive how it would be possible to improve them, except by the addition of living or moving objects.

STEAM NAVIGATION.

RENNIE'S PATENT TRAPEZIUM PADDLE WHEELS.

The object of the above patent is to do away with the defects of the common rectangular paddle wheel, arising out of its great width, weight, and indirect action, and to substitute in its place a wheel which, while it retains the simplicity, obviates the defects of the common paddle wheel. The Trapezium paddle wheel differs only from the common paddle wheel in the form of its floats, which are trapezoidal or spear-shaped, and in the greater simplicity of its construction. The advantages to be derived from this form are a wheel of one half the breadth, one half the weight, and one half of the surface of the common recangular paddle wheel. These advantages require no comment, provided that the form of wheel be equally efficient, and this has been proved by a series of experiments on two separate steam vessels, in opposition to their usual wheels. From the peculiar form of the floats, they enter into the water with the pointed part of the float downwards, and thus gradually arrive at their full horizontal action without shock or vibration, while, after the stroke, they, in the reverse manner, quit the water without raising any portion of it behind. Of course the advantages, arising out of the diminished breadth of a vessel fitted with trapezium-shaped floats, will be, less space occupied in a river, basin, or lock; less surface resistance to a head wind, by all the breadth of one wheel; lighter draught of water, by the diminished weight; less oscillation sideways, and consequently less liability to occasion damage to the engines. The shocks and vibrations now experienced by the striking of the edges of the rectangular paddle wheel against the surface of the water, and the loss of power occasioned in consequence by the oblique action of the wheels both in going into and out of the water will be entirely prevented. Finally, that that the Trapezium paddle wheel will work nearly as efficiently when deeply immersed as when immersed to the usual depth, thus enabling the wheels to work with nearly the same facility at the first as at the last part of a vessel's voyage. All these advantages are obtained without the aid of wheels, eccentrics, or complicated levers of any kind, but simply an alteration in the form of the floats; H. M. ship *African* is now being fitted with Trapezium paddle wheels, instead of her former rectangular paddle wheels.

North American.—In a week or ten days (says the *New York Herald*) one of the most substantial and splendid steam ships in the world will be launched in this city. This steam ship, or steam frigate rather, is owned by Nicholas, Emperor of Russia. She is of immense size, and has been building since last spring. Her dimensions are as follow:—Length of deck 220 feet; length of keel 210 feet; breadth 36 feet; full depth 21½ feet; tonnage 1,500. She is constructed of live and white oak, but mostly of the latter kind, weighing, we believe, about fifty pounds to the cubic foot. She will draw, when launched, ten or eleven feet of water and no more. But when her engines, and boilers, and guns, and all her machinery and her fuel of which she can carry [illegible] eight hundred tons, [illegible] she will pro[illegible] [illegible] The [illegible] of this great war steamer was [illegible] by two officers of the Russian Navy. [illegible] of the steam frigate—no vessel of the kind that [illegible] crossed the A[illegible] [illegible] She is superior to the *Western*, the *Queen*, and the *President*. Her bows are sharp—her stern is round—her lines [illegible] gradual and symmetrical—her wheel-houses [illegible] and not too large, and her whole appearance is rich, attractive, and manof-war like. She has three masts, which, together with her rigging, are very light. This will contribute, in a great degree, to her speed against head winds. Large [illegible] spars are decidedly bad, when winds are unfavourable. Her internal arrangements will be [illegible] [illegible] Her armament is to be very formidable. She can discharge at every broadside more than four hundred pounds of shot! She will mount sixteen fifty-four and thirty-two pounders on the second deck, and two ninety-six pounders hollow shot, called by the humane, death dealers, on the upper deck, which is flush fore and aft—a clear run of two hundred and twenty feet. Her engines will be about six hundred horse power. They will be [illegible] to the ship, for no expense is to be spared in having them perfect. What her speed will be, is, of course, not yet known. We can only guess that she will go pretty fast, if not faster. Another account says—A splendid steam frigate, built at New York, for the Emperor of Russia, was launched on the 24th November. She is to be called the *Kamtschatka*, and is of the burden of 2,281 tons, of the length of 240 feet 6 inches. Breadth across the paddle wheels, 66 feet. Her armament is to consist of twelve 36 pounders, four 54 pounders, and two 96 pounders for throwing hollow shot.

Steam Navigation.—If the French Government carry their projection for admitting the importation of foreign marine steam engines free of duty, it will give extensive employment to the engine manufacturers in this country, and greatly extend French steam navigation.

West India Mail Steam Packet Company.—This Company have in hand 14 steam vessels of 1400 tons burthen, each to be fitted with a pair of engines of 220 horse power—6 pair are being made in the Clyde, 2 pair by Fawcett and Co., 2 pair by Maudslay and Field, 2 pair by Miller, Ravenhill and Co., and 2 pair by Acraman and Morgan—the parties are under heavy engagements to have them ready within a very short time.

New York.—We believe that we are at last enabled to announce the establishment of a New York line of steam ships between New York and England. The preliminaries are, we understand, nearly completed, and within a short time the keels of four gigantic vessels will be laid. They are to be about 2,000 tons, with engines of 800-horse power.—*New York Commercial Advertiser.*

The City of Dublin Steam-packet Company.—We understand that this Company have decided on laying down two new steamers immediately, to run in conjunction with their unrivalled vessels, the *Prince* and *Princess*, to and from Kingstown. As the utmost speed that can be attained is determined on without regard to expense, the contracting parties are bound, under heavy penalties, to construct them to outstrip any sea-going steamer afloat; and it is confidently anticipated, that the average passages will not exceed nine hours.—*Liverpool Albion.*

PROGRESS OF RAILWAYS.

GRAND JUNCTION RAILWAY.

Expenditure to December 31, 1840.

Engineering, surveying, parliamentary, legal and general expences; construction of line and works, stations, land and compensation, rails, chairs, &c.	1,616,606	10	10
Locomotive engines and tenders, and establishment—carriages, wagons, trucks, and horse boxes	228,694	16	0
Purchase of Warrington & Newton line	65,463	7	4
Purchase of Chester and Crewe line	192,550	0	0
Expended to Dec. 31, in works, &c. on Chester & Crewe line	65,475	14	3
Interest on loans previously to the completion of the line	22,270	18	3
Arrears of fourth call on half-shares, less received on account of fifth call on do., and Warrington & Newton interest not applied for	1,585	8	9
Total	£2,192,046	15	5

Value of Stock, December 31, 1840.

Locomotive Engine Department	109,215	6	8
Waggon, horse box, and carriage truck department	53,451	7	5
Coach-building department	51,843	14	3
Total value	£214,510	8	4

Manchester and Birmingham Railway.—The Directors of the Railway have, by a *unanimous* vote, awarded to John Byth, Esq., V.P. of the Architectural Society of London, and R. Cromwell Carpenter, Esq., F.S.A., the premium of two hundred pounds for their designs for the Manchester Station.

The Strasburg and Basle Railway Company has just received from the bank of France the sum of 1,200,000f. on a warrant from the treasury, being the first of the three instalments of 12,000,000f. which the French government is authorised to lend it. The Company therefore is about to adopt additional measures for carrying on their works.

LONDON AND BIRMINGHAM RAILWAY.

Expenditure to December 31, 1840.

To land and compensation	721,556	17	3
To works of road and stations	4,348,269	12	5
To locomotive stock, viz.—engines, tenders, tools, and implements	154,635	0	7
To carrying stock, viz.—coaches, trucks, wagons, cranes, &c.	195,310	5	0
To charges, viz.—			
Obtaining act of incorporation	72,858	18	10
Law charges, conveyancing, engineering, advertising, and printing, direction, office expenses, salaries, and sundries	172,175	9	0
To interest on loans, previous to general opening, 17th Sept. 1838, and debenture charges	127,649	8	6
Total	£5,792,475	8	7

Value of locomotive engines and carriage stock, Dec. 31, 1840	£319,945	5	7

394,088 passengers travelled on this railway during the last year, each an average distance of 65½ miles.

LONDON AND GREENWICH RAILWAY.

Extracts from the last Report.

The cost of locomotive power, per train, has been 1s. 2¾d. per mile.

Relaying of the line, together with the asphalting over nearly 500 arches have been completed, and the new rails on cross sleepers laid thereon, and, so soon as the season of the year will permit, the remainder will be proceeded with.—1,506,730 passengers were safely conveyed over this line during the past year.

In conformity with an act obtained last session, empowering the Company to increase the width of the railway from the London station to the junction with the Croydon Railway, so as to admit of four lines of way instead of two, as heretofore, two contracts have been entered into for widening the railway as above mentioned, and which extend over about 2,400 yards, leaving only about 660 yards of the line and the addition to the station to be contracted for. A list of the tenders for the first contract was given in the Journal for last December, and we now annex a list of tenders for the last contract.

Messrs. Little & Sons	£16,350
Messrs. Lee	17,628
Mr. Jackson	17,650
Messrs. Grissell & Peto	17,734
Mr. Grimsdell	17,986
Mr. Munday	17,988
Messrs. Ward	18,650
Mr. Bennett	18,764
Messrs. Baker & Son	19,340
Mr. Mac Intosh	21,283

BLACKWALL RAILWAY.

List of Tenders for the extension from the Minories to Fenchurch-street, delivered in on the 23rd ult.

Jackson	£29,800
Webb	30,333
Baker and Son	31,888
Lee	32,333
Piper	32,690
Grissell and Peto	33,000
Grimsdell	33,120
Cubitt	33,940
Bridger	34,900

Stockton and Hartlepool Railway.—On Tuesday the 10th ult., this new Railway was opened by the Directors, and on the following day to the public. It connects the flourishing ports of Stockton and Hartlepool, and must prove a convenient means of communication between the two places. The undertaking altogether reflects the highest degree of credit on the public-spirited company who are engaged therein, and also on the talented engineers and their assistants, and the contractors who have been employed in executing the work. In point of fact, we shall not overstate our feeling on this subject, if we remark that the way in which the works have been finished on the Stockton and Hartlepool railway affords a model of railroad construction. Messrs. George Leather and Son, of Leeds, are the engineers-in-chief, and Mr. John Fowler, their assistant, was the resident engineer.—*Leeds Mercury.*

Railway to Cambridge.—In the last month there have been no less than three different surveys between Bishops Stortford and Cambridge, one for extending the line of the Northern and Eastern Railway to the latter place; one line by the East Anglian Railway; and the other for the railway to York, through Lincoln. We certainly think it a great fault in the present state of affairs for new companies, as in the above case, to attempt to do too much. It would have been far better for the projectors of the lines from Norwich and York, to have made an arrangement with the Northern and Eastern Railway Company to have completed their line to Cambridge, from which the other two lines could then have diverged, and at some future time a line to the westward, through Bedford to Rugby, and unite with the London and Birmingham Railway. By such a step the expense of conflicting surveys, and perhaps of a parliamentary contest would be avoided, and the Eastern Counties really benefited.

The Sheffield and Manchester Railway.—It appears the works in the centre tunnel are going on night and day, the men working in shifts." But when we find it is three miles, or 5,280 yards in length, and there are five shafts sunk of the following depths, some time must elapse before this great work is finished:—Shaft No. 1, 180 yards deep; No. 2, 194 yards; No. 3, 169 yards; No. 4, 193 yards, No. 5, 135 yards.

The Cromford and High Peak Railway.—The application of the locomotive engine to the purposes of railway transit on this line, was made about a fortnight since, several of the proprietors accompanying the engine. The intention is to construct, as speedily as possible, two more engines to work the two twelve mile levels between Hopton and Buxton, at a rate of from ten to twelve miles per hour, so as to enable the Company to transport goods and passengers to Whalley Bridge in a few hours, instead of two days, which it now usually takes.—*Sheffield Iris.*

The Taff Vale Railway.—The operations for finishing the line are going on with great vigour, particularly at the Merthyr Terminus, where a great number of men, carpenters, masons, and labourers are at present busily employed. The damage caused by the late sudden rise in the river, has, we are glad to hear, been greatly overstated, as a comparatively small sum will suffice to repair it. A wall is now building on the bank of the river, which will be built so strong as to prevent the recurrence of a like calamity, and the void caused by the earth having been carried away is now being filled up.—*Monmouth Gazette.*

Great North of England Railway.—Mr. Storey has resigned the office of Engineer-in-chief, who has been succeeded by Mr. Robert Stephenson.

ENGINEERING WORKS.

Crown Point Bridge.—The Commissioners of the Crown Point Bridge and Roads met at the Court-house, in Leeds, on Monday the 15th ult., for the purpose of letting the works of this bridge, when tenders were received from many highly respectable contractors, and the competition was, we are informed, exceedingly close. The bridge is to be thrown over the river Aire, a little above the Nether Mills Weir, or from Chadwick's dye-houses on the south side (part of which will have to be removed in order to make way for it), to Medley's Oil Mill on the north side; and when the roads to and from its site are completed, it will open out a direct communication from Hunslet-lane and the southern parts of the town to York-street and the northern and eastern district of the town. The design for the iron bridge, prepared by Messrs. George Leather and Son, the engineers, of this town, is one of the most tasteful and elegant we have ever seen, combining in a remarkable degree symmetry and lightness with strength. The bridge will be of one arch, including in its span the whole width of the river and the towing path on its side. The span will be 120 feet, (that of Victoria bridge being only 80 feet), the rise of the arch 12 feet, but the height, from the water of the river to the waterside, of the arch at the crown will be 17 feet, and to the roadway of the bridge about 22 feet. The width within the parapets will be 42 feet; there being a Macadamized carriage way of 10 yards wide, with a footpath or causeway of two yards wide on each side. The arch upon which the road is to be constructed will be entirely of iron; the abutments and wing walls will be of stone. The total weight of iron is estimated at about 420 tons. The masonry was let to Messrs. Bray and Duckett, who have executed works in a very creditable and satisfactory manner on the North Midland Railway, and who are also contractors for the works now in progress for the Leeds Waterworks Company, on Woodhouse Moor. The ironwork was let to Messrs. Booth and Co., of Park Ironworks, Sheffield, who are also a firm of the first respectability. The sum at which the bridge let for was, we understand, £8,750, being somewhat lower than the estimate of the engineers, so that the commissioners have every reason to consider the bridge favourably let, not only as regards the respectability of the contracting parties, but also as regards the terms on which it was taken. The work will be commenced forthwith, and the terms of the contracts are such as to ensure its being carried forward with vigour, and it is confidently anticipated that this bridge may be opened for the use of the public at the close of the present year.—*Leeds Mercury.*

Portsmouth Harbour.—A most complete survey of the Portsmouth Harbour, with its various lakes and approaches, has recently been made by Lieuts. Sherringham and Otter, and their assistants, including a minute map of the towns. The most extraordinary coincidence exists, we understand, between the present survey, with all the improved methods, and still more improved instruments, and the old survey of Mackenzie, made in 1782, and the still more recent one of the late talented and industrious Mr. Park, who was then Master Attendant here; and, still more extraordinary, the soundings, all over, have varied only in the slightest degree in the period alluded to, 60 years. The bar off the Southsea land-marks remains unaltered from its shape and size as recorded in the oldest minutes; and we find it consists of no shifting matter, but is a firm substance of flint and chalk, almost concreted together with gravel; it could be channelled with much ease, but with some expense.

The Shannon Improvement.—Two steam dredging machines have commenced operations on the shoals of the river near Banagher. One of the machines it is stated, removed 38 tons of clay intermixed with gravel in 20 minutes. Besides the dredging operation, works have been contracted for at Killaloe, Meelick, Banagher, and Athlone.

An Iron Bridge has been constructed at Nantes, on the same principle as that adopted by M. Polonceau, on the Pont du Carousel, drawings of which and a description will be found in the 2nd volume of the Journal. The bridge of Nantes is of one arch, about 66 feet span, and the width of the road way 40 feet.

MISCELLANEA.

Artificial Staining of Marble.—This art was practised by [illegible] and is described by Zanon [illegible] considerable [illegible] at Verona. The results are as follows:—A solution of nitrate of silver penetrates the marble, and communicates a deep black colour to it. A solution of nitrate of gold penetrates less deeply, and communicates a beautiful purple violet colour. Verdigrise sinks to the depth of a line into the marble, and gives it a fine green colour. A solution of dragon's blood communicates a beautiful red colour, and gamboge a yellow tint. To apply these two colours it is necessary to polish the marble with a pumice stone, to dissolve the gum resins in hot alcohol, and put them on with a camel-hair pencil. The tinctures obtained from woods, as Brazil wood, logwood, &c., penetrate deeply into marble. Tincture of cochineal, with the addition of a little alum, gives marble a fine scarlet colour, similar to African marble. Artificial orpiment produces, when dissolved in ammonia, a lively yellow colour. If verdigrise be boiled with white wax, and the mixture be applied to the marble, and then removed when it has cooled, it will be to have penetrated five lines, and to have produced a fine emerald colour. When it is wished to apply the different colours in succession, some precautions are necessary. The tinctures prepared by spirit of wine and by the oil of turpentine are to be applied to the marble while it is hot; but the dragon's blood and gamboge are to be used with the marble when cold. For this purpose, it is necessary to dissolve them in alcohol, and employ the solution of gamboge first. This, which is clear, soon becomes turbid, and affords a yellow precipitate. Those parts of the marble which are covered with the tincture are then to be heated, by passing over them, at the distance of half an inch, a red-hot iron plate, or a charcoal chauffer; it is then allowed to cool, and the iron is again passed over those portions where the colour has not penetrated. When the yellow colour has been imbibed, a solution of dragon's blood is to be applied in the same manner; and, while the marble is hot, the other vegetable colours may be communicated. The last colours to be applied are those in union with the wax. These must be used with great caution, because the slightest excess of heat causes them to penetrate deeper than is necessary, which renders them less adapted for delicate work. During the operation, cold water should be occasionally thrown upon them.—*Athenæum.*

Height of Waves.—The highest wave which struck the French ship *Vénus,* during her voyage, was 7·5 metres (23 feet); the longest wave was met with in the south of New Holland, and was three times the length of the frigate, or 150 metres (492 feet).

The quantity of Air necessary for the Healthful Respiration of the Horse.—The Committee of the Academy of Paris, to whom this question was referred by the Minister of War, have reported, that in a building where the air is properly renewed, and that result is effected by a skilful and efficient system of ventilation, a horse can never suffer, so long as he has from 25 to 30 cubic metres of air.

A new method of nailing deck plank has been adopted in the upper deck of the Driver steamer, the invention of Mr. Blake, by which the expense of copper or composition nails in the deck may be saved, simply by punching the nails down one inch, and filling the hole with a circular plug dipped in white lead.

Reflecting Telescope.—Unfortunately Sir William Herschel never made public the means by which he succeeded in giving such great development to this telescope, and the construction of a large reflector is still a perilous adventure. According, however, to a report by Dr. Robinson to the Irish Academy, Lord Oxmantown has overcome the difficulty, and carried it to an extent, which even Herschel himself did not venture to contemplate, the illuminating power of this telescope, along with a sharpness of definition little inferior to that of the achromatic; and it is scarcely possible, he observes, to preserve the necessary sobriety of language in speaking of the moon's appearance with this instrument, which Dr. Robinson believes to be the most powerful ever constructed. However, any question about this optical pre-eminence is likely soon to be decided, for Lord Oxmantown is about to construct a telescope of six feet aperture, and fifty feet focus, mounted in the meridian, but with a range of about half an hour on each side of it.

Hotel de Trémouille.—All who take an interest in Parisian antiquities, may be glad to know, that the demolition of the Hôtel de Trémouille, in the Rue des Bourdonnais, is not to include that of the beautiful little tower which forms the conspicuous ornament of its principal court. The proprietors have presented this fine relic of the architecture of the 13th century to the city,—and it is about to be transported to the Museum of Historical Monuments.

Head of the Laocoon.—The following statement has appeared in the French papers, and is professedly contained in a letter from M. Valmore, an artist at Brussels—"In the gallery of the Duke d'Aremberg there are many things which are not known to any but the initiated. Among them is *the original head of the Laocoon.* This fine group, when first discovered in Italy, was," as is generally known, "without the head of the father, and an arm of one of the sons. The head was supplied by a celebrated artist, who copied it from an antique bas relief. Some time afterwards, the original was found by some Venetian connoisseurs, and was ultimately sold to the grandfather of the Prince for about 160,000 francs, and brought to Brussels. When Napoleon, during the Consulate, had the group transported into France, he knew that the real head was in possession of the Duke, and offered him his weight in gold for it. This was refused; and as it was known that Napoleon was not scrupulous in gratifying his desires, the Duke d'Aremberg sent this *chef-d'œuvre* to Dresden, where it remained concealed for ten years, but was brought back again into Brussels, when Belgium became tranquil. It expresses, in the highest and most admirable degree, moral grief mingled with physical pain. The compression of the teeth and contraction of the lower jaw are almost too horrifying to be long contemplated; and yet in this intense expression of suffering there is not the slightest grimace. The pupils of

Cornwall.—A new Episcopal Chapel is now erecting at Flushing, in the parish of Mylor. The building is constructed from the designs, and under the superintendence of Mr. Wightwick, of Plymouth. It is in the Anglo-Norman style, and calculated to accommodate 250 sitters, without reckoning the gallery, which it is not proposed in the first instance to erect. Lord Clinton is the chief private subscriber, and the London Incorporated and Local Diocesan Societies, have afforded also liberal assistance.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 30TH JANUARY, TO 23RD FEBRUARY, 1841.

Six Months allowed for Enrolment.

Charles Schafhautl, of Swansea, Doctor of Medicine, Edward Oliver Manby, and John Manby, of Parliament Street, Civil Engineers, for "*improvements in the construction of puddling, balling, and other sorts of reverberatory furnaces, for the purpose of enabling anthracite, stone coal or culm to be used therein as fuel.*"—Jan. 30.

James MacLellan, of Glasgow, Manufacturer, for "*an improved combination of materials for umbrella and parasol cloth.*"—Jan. 30.

Ezra Jenks Coates, of Bread Street, Cheapside, Merchant, for "*improvements in the forging bolts, spikes, and nails.*" Communicated by a foreigner.—Jan. 30.

Henry Pape, of Great Portland Street, Piano Forte Manufacturer, for "*improvements in castors.*"—Feb. 1.

Charles Hood, of Earl Street, Blackfriars, Iron Merchant, for "*improvements in giving signals.*"—Feb. 1.

William Wilkinson Taylor, of Barrowfield House, Essex, Gentleman, for "*improvements in buffing apparatus for railway purposes.*"—Feb. 1.

Dominic Frich Albert, of Cadishead, Manchester, L.L.D., for "*an improved or new combination of materials and processes in the manufacture of fuel.*"—Feb. 1.

Francis Sleddon, jun., of Preston, Machine Maker, for "*improvements in machinery or apparatus for roving, slubbing, and spinning cotton and other fibrous substances.*"—Feb. 2.

William Ward Andrews, of Wolverhampton, Iron-monger, for "*improved methods of raising and lowering windows and window blinds, and opening and shutting doors, which are also applicable to the raising and lowering of maps, curtains, and other articles.*"—Feb. 2.

Thomas Young, of Queen Street, London, Merchant, for "*improvements in furnaces or fire places for the better consuming of fuel.*"—Feb. 3.

William Hancock, jun., of King Square, Middlesex, Accountant, for "*an improved description of fabric suitable for making friction gloves, horse-brushes, and other articles requiring rough surfaces.*"—Feb. 3.

Joseph Bunnett, of Deptford, Engineer, for "*certain improvements in locomotive engines and carriages.*"—Feb. 3.

John Cartwright, of Loughborough, Manufacturer of Hosiery, Henry Warner, of the same place, Manufacturer of Hosiery, and Joseph Haywood, of the same place, Frame, Smith, for "*improvements upon machinery commonly called stocking frames or frame work knitting machinery.*"—Feb. 4.

Thomas Griffiths, of Birmingham, Tin Plate Worker, for "*improvements in such dish covers as are made with iron covered with tin.*"—Feb. 8.

James Thorburn, of Manchester, Mechanist, for "*certain improvements in machinery for producing knitting fabrics.*"—Feb. 8.

William Ryder, of Bolton, Lancaster, Roller and Spindle Maker, for "*improved apparatus for forging, drawing, moulding, or forming spindles, rollers, bolts, and various other like articles in metals.*"—Feb. 8.

Thomas Fuller, of Salford, Machine Maker for "*improvements in machinery or apparatus for combing or preparing wool or other fibrous substances.*" Partly communicated by a foreigner.—Feb. 8.

Elisha Oldham, of Cricklade, Wilts, Railroad Contractor, for "*improvements in the construction of turning tables to be used on railways.*"—Feb. 8.

Charles Green, of Birmingham, Gold Plater, for "*improvements in the manufacture of brass and copper tubes.*"—Feb. 8.

William Wigston, of Salford, Engineer, for "*a new apparatus, for the purpose of conveying signals or telegraphic communications.*"—Feb. 8.

Joseph Scott, of Great Bowden, near Market Harborough, Timber Merchant, for "*improvements in constructing railways, and in propelling carriages thereon, which improvements are applicable to raising and lowering weights.*" Feb. 8.

James Johnstone, of Willow Park, Greenock, Esquire, for "*improvements in motive power.*"—Feb. 8.

William Henry Fox Talbot, of Locock Abbey, Wilts, Esquire, for "*improvements in obtaining pictures or representations of objects.*"—Feb. 8.

William Edward Newton, of Chancery Lane, Mechanical Draughtsman, for "*improvements in obtaining a concentrated extract of hops, which the inventor denominates 'humuline.'*" Communicated by a foreigner."—Feb. 8.

Theophilus Smith, of Attleborough, Farmer, for "*improvements in ploughs.*"—Feb. 15.

James Whitelaw and George Whitelaw, Engineers, of Glasgow, for "*a new mode of propelling vessels through the water, with certain improvements on the steam engine when used in connexion therewith, part of which improvements are applicable to other purposes.*"—Feb. 15.

Philip William Phillips, of Clarence Place, Bristol, Gentleman, and William Bishop Beck, of Broad Street, Bristol, Wine Merchant, for "*improvements in four wheeled carriages.*"—Feb. 15.

James Ransome, and Charles May, of Ipswich, Machine Makers, for "*improvements in the manufacture of railway chairs, railway or other pins or bolts, and in wood fastenings, and trenails.*"—Feb. 15.

William Scamp, of Charlton Terrace, Woolwich, Surveyor, for "*an application of machinery to steam vessels, for the removal of sand, mud, soil, and other matters from the sea, rivers, docks, harbours, and other bodies of water.*"—Feb. 16.

William Samuel Henson, of Allen Street, Lambeth, Engineer, for "*improvements in steam engines.*"—Feb. 16.

George Edward Noone, of Hampstead, Civil Engineer, for "*improvements in dry gas meters.*"—Feb. 18.

William Orme, of Stourbridge, Ironmaster, for "*improvements in the manufacture of coffered spades, and other coffered tools.*"—Feb. 18.

John Collard Drake, of Elmtree Road, Saint John's Wood, Land Surveyor, for "*improvements in scales used in drawing, and laying down plans.*"—Feb. 18.

Anthony Bernhard Von Rathen, of Kingston-upon-Hull, Engineer, for "*improvement in fire grates, and in parts connected therewith, for furnaces for heating fluids.*"—Feb. 22. (Four months.)

William Newton, of Chancery Lane, Middlesex, Civil Engineer, for "*improvements in the process of and apparatus for purifying and disinfecting greasy and oily substance, or matters both animal and vegetable.*" Communicated by a foreigner.—Feb. 22.

Thomas William Booker, of Merlin, Griffiths Works, near Cardiff, Ironmaster, for "*improvements in the manufacture of iron.*"—Feb. 22.

Jonathan Guy Dashwood, of Ryde, Isle of Wight, Plumber, for "*improvements in pumps.*"—Feb. 22.

Moses Poole, of Lincoln's Inn, Gentleman, for "*improvements in tanning, and dressing, or currying skins.*" Communicated by a foreigner.—Feb. 22.

Charles Sneath, of Nottingham, Lace Manufacturer, for "*improvements in machinery, for making or manufacturing of stockings or other kinds of loop work.*"—Feb. 23.

John Dean, of Dover, Chemist, for "*improvements in preparing skins and other animal substances, for obtaining gelatine, size, and glue, and in preparing skins for tanning.*"—Feb. 23.

TO CORRESPONDENTS.

A. Q. Z. *We cannot give the description he requires, it has already appeared in several publications.*

G. H. S. *The rules he requires we shall publish at some future opportunity, but not at present.*

Mr. Hance's *communication will be noticed next month.*

The Wesleyan Centenary Hall and Mission House next month.

An Old Subscriber *will feel obliged if any of our readers can inform him, the process of printing Transparent Window Blinds.*

Communications are requested to be addressed to "The Editor of the Civil Engineers and Architect's Journal," No. 11, *Parliament Street, Westminster.*

Books for Review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume.

ERRATUM.

At page 58, line four from the top of the first column, for "In all *our* architectural drawings," read "In all *old* architectural drawings."

NOTES RELATIVE TO TOWING PATHS AND BANKS OF CANALS IN GREAT BRITAIN.

By M. Vuigner, Inspector of the Paris Canals.

(With an Engraving, Plate IV.)

(Translated from the French.)

M. Vuigner, being commissioned by the company of the Ourcq and St. Denis canals to study the various systems of works in use on the British canals, and particularly to examine the different methods used in forming the foundations of the hauling or towing paths, and protecting the slopes of the interior banks from the effects produced by the ordinary and irregular fluctuations of the water, he visited, for this purpose, in the course of 1837, the canals of that country, which stand the first in construction, and collected considerable information on the subject.

In England the canals of Taunton & Bristol, those of Birmingham, (from Liverpool to Leeds) Preston & Lancaster, in Scotland those of Paisley or Ardrossan, the Forth and Clyde, and the Union Canals, furnished him with every information that could be required. On his return to France, the company, who wished to establish on the Ourcq canal a set of passage boats, empowered M. Vuigner immediately to apply the information he had acquired. He was first engaged to macadamize the towing path of the left bank of the Ourcq canal between La Villette and Meaux, and caused part of its banks to be improved, and he also applied some improvements resulting from his observations in Great Britain.

The present paper will contain a description relative to the *metalling* of the towing paths, and the protecting of the banks on the English and Scotch canals, as well as describing the macadamizing and facing used on the Ourcq canal to prevent damage by the action of the water.

Towing or Hauling Paths.

In England there is generally only one towing path, though, upon some new lines, especially the Birmingham, there are two paths. This is an exception which a particular circumstance required, but which, however, is not a deviation from the general rule. The Birmingham has a towing path on both sides until it is divided into two branches, one to Wolverhampton, and the other to Walsall, each having their towing paths, one on the right side and the other on the left. On that part where there is a towing path on each bank, the navigation is extremely active, amounting to more than 1000 boats per week. The navigation is facilitated, and at the same time the horses that tow the boats coming from Wolverhampton and Walsall have not to change their sides, nor obstruct one another. The breadth of the towing paths is generally not more than 10 feet, which is considerably less on some canals, and especially at Taunton, a canal of very small section, navigated by boats of only 10 tons.

On the new line of the Birmingham canal, the breadth of the towing path in cuttings is about 12 feet, and on embankments 15 feet. The path is generally divided into three parts, one part next the canal forms a fender or raised mound 1 ft. 6 in. to 2 feet wide, which is turfed over, the middle part forms the trackway for the horses, and is covered with metalling or broken stone to the width of five or six feet, and the other part is the remainder of the land unappropriated; sometimes it contains a drain for carrying off the surface water, and is enclosed with a hedge which determines the limit of the canal property. On the opposite bank, there is, in some parts, a footpath about 3 feet wide, but more frequently the underwood or cultivated land reaches to the water's edge, so that no more land is taken than what is absolutely necessary for the canal.

On the Preston, Lancaster, Paisley, Forth & Clyde, and Union Canals, where there are fast passage-boats, the width reserved for the fender between the towing path and the interior slope of the canal, is on the average two feet wide at the base, and raised from 6 to 8 inches above the path, or from 2 ft. to 2 ft. 6 in. above the surface of the water, the top, about 1 ft. to 1 ft. 4 in. wide, is generally turfed over. The interior edge forms the continuation of the interior slope of the canal, and the outer edge is sloped and protected with large round pebbles placed at intervals of 2 to 3 feet, which are partly imbedded in the earth, and project about 2 inches above the fender: these pebbles are now abandoned, as they were found inconvenient for the towing ropes when the speed was slackened. On some parts of the canals the fender is formed of flat stones, the edge of which forms the top of the stone facing of the bank, as shown in sections, Figs. 17, 18, and 19. The fenders answer the purpose for limiting the track of the horse, preventing the mud being washed over the path, and a protection to the edge of the slope.

The towing path of the above canals is mostly formed of a layer of broken or round pebbles laid to a thickness of 4 to 6 inches according to the nature of the soil, and then covered with a layer of gravel from 1 in. to 1½ in. thick. On some parts marly clay is used to bind the pebbles, and on other parts, especially at the stopping places, at the bridges, and even the whole length of the Paisley canal, the pebbles are covered with a layer of iron slag, which, when well beaten in, forms a path extremely hard and compact, besides, it is not slippery in rainy weather, and is free from dust in summer. The broken pebbles used are generally not larger than 1½ inch at most. The best macadamized paths are those made of broken limestone, and better still with basalt; these materials are found nearly every where on the banks of canals, which renders their formation and repair very cheap.

The transverse slopes of the towing path, where there are fast passage boats, have an inclination of about 2 inches to the yard declining from the canal: this inclination is found to give the best hold for the horses' feet. The surface water is carried off on the outside of the path, and is seldom allowed to run into the canal, excepting in such parts where the canal is formed in cutting; it is then carried off by under drains of dry stones, which pass under the towing path transversely from longitudinal gutters or drains, formed on the outside of the path.

Towing Paths of L'Ourcq Canal.

The towing paths of this canal, and in general on all the French canals were formed on the natural soil, without the least metalling or stoning of any sort: in winter time they were quite impassible in parts, especially in the Paris division, between La Villette and Claye. In this state of things it was difficult to think seriously of establishing passage boats, which the Ourcq and St. Denis canal company was desirous of introducing into France; they therefore determined upon adopting the English system of macadamizing the towing path of the left bank of the Ourcq canal between La Villette and Meaux. On the Ourcq canal the ordinary boats are towed up by one horse; but the passage boats, as well as the Government boats, are towed by two horses abreast, as well going up as down, which is still the case. The experiments which were made on the speed of passage boats, showed that three horses, two horses abreast in front and one behind, were necessary for towing these boats. It thus became necessary to increase the width of the towing path. In those places where the banks had retained their first form the breadth of the path was 13 ft., which was diminished to 11 ft. 6 in., where the banks were raised 1 ft. 6 in. above the surface of the water. The towing path is now reduced throughout to a breadth of 9 ft. 6 in., consisting of a fender 2 ft. wide at the base, the trackway for the horses 6 ft. 6 in. wide, and a drain 13 inches wide. In the Meaux division they have only allowed a breadth of 6 feet for the towing path, but the drain has been increased to 19 inches wide, which still gives a breadth of near 8 feet upon which the horses can walk or run with ease. This breadth might be considered insufficient at the points of crossing, where four horses have to pass; but the company decided that in case that should occur, they would cause the front horses to be harnessed one before the other. Another important consideration which determined the company to adhere to 9 ft. 6 in. was that of economy, as it would involve an extension of the work for more than 30 miles between La Villette and Meaux, and double that distance if extended between La Villette and Mareuil.

Experience has proved that the adopted width is sufficient for the different boats, as the horses of the passage boats in general never pass each other, excepting at the different stages, where the path is widened. As regards the horses of the other boats when they pass, the horses go a little on one side, or on to the exterior slopes, and if it be found too inconvenient to act thus, it is immediately obviated by harnessing the horses one before the other as before observed.

The breadth being settled, it then became necessary to fix the height of the towing path above the surface of the water. Between La Villette and Meaux the top of the interior slope was 8 ft. above the bottom, but between La Villette and Claye it was only 6 ft. 6, and from Meaux to Claye 5 feet, so that the same height of path could not be adopted throughout. Between La Villette and Meaux the height of the fender was fixed at 2 ft. 6 in. above the soffice of the water, and 6 inches above the towing path, which made the latter 2 feet above the water, as shown in sections, Figs. 5, 7, & 11.

The paths were formed in some places with broken limestone, in other places with clean pebbles mixed with sand or coarse gravel, and laid to a thickness of 4 to 5 inches, and covered with a layer of gravelly sand from 1 in. to 1½ in. thick; the pebbles, when mixed with coarse gravel, were used without an extra coat, and laid to a thickness of 6 inches. As soon as the paths were finished, a roller 5 feet broad, drawn by 3 horses, were passed over them: this roller was constructed on the Polonceau principle, and made of wood lined on the inside with lead, and the outside covered with sheet iron, and filled with sand: it weighed 3 tons.

Interior Slopes.—In ordinary canals the exterior slopes are frequently of earth turfed, and if they have stone or timber facing at any point it is generally in those places where there are wharfs, however, on the Birmingham Canal stone and timber facings have been substituted in the upper part for earth banks, the slopes having been preserved below the surface of water as a counterpoise to the masonry and timber work, this method shown in section fig. 8, allowed the wharf walls to be made thinner, and the stakes or piles of the timber facing to be reduced to a minimum length. Thus the foundation of the masonry hardly goes down to the level of the bottom of the canal, and the piles are not driven to a greater depth, these piles are placed from 3 to 4 feet apart from centre to centre, and have a capping or campshed 7 inches square, which serves as a support to the planks placed behind to keep up the ground between one pile and another: these timber facings are very simple and very cheap, and may be made at all seasons without forming a coffer-dam, or laying the canal dry.

Ardrossan or Paisley Canal.

The section of this canal is shown in fig. 9, the breadth at top is 35 feet, depth below the ordinary surface of the water 4 feet, and 6 feet from the top of the banks to the bottom. The banks are faced with stone as shown in figs. 9, 12, and 13. In section fig. 9, the stone facing is laid 16 inches below the water surface, and 12 inches above: it is constructed with 4 courses of rough stone laid dry and scabbled on the face, the lower course projects forward, and small stakes are driven every 2 feet at the base, to protect the stone work. Section fig. 12, is constructed in a similar manner, excepting the stones are larger and in 3 courses, and have no stakes to protect the foundation. Section fig. 13, has 4 courses of large stones as fig. 9, but they are set like steps. These two last sections were only tried by way of experiment, that which is now adopted is shown in fig. 9, it gives the greatest resistance, and is best calculated to deaden the action of the waves, or surge of the water, and at the same time the most economical.

Forth and Clyde Canal.

This canal has a mean breadth of 60 feet at the top, and 8 feet deep below the water surface, and 12 feet deep below the top of the bank; different methods of lining the banks have been adopted to prevent the abrasion of the banks by the action of the water, occasioned by the establishment of quick passage boats, as shown in sections figs. 10, 15, 16, 17 and 18. On the towing-path bank of section fig. 10, the facing is laid in the same manner as in fig. 9, of the Ardrossan Canal, excepting the courses of stone are more numerous, and there are no stakes to protect the foundation. On the opposite bank, as those points most likely to be affected, they are cased with rubble work. Section fig. 15, shows a broad bench at the bottom, and the stone facing laid on a slope of 45°, which is carried up to one foot above the water surface. Section fig. 18, the stones are laid on a slope and continued up to the top of the bank, which is capped with a flat stone 1 foot 8 inches wide. Section fig. 16, shows another method of construction, the stones are laid to the form of the curve of degradation: the stone work does not extend more than 12 to 15 inches below the water level, and the same same height above. Section 17, consists of 4 courses of basalt, each 10 inches high and 1 foot 8 inches to 2 feet deep, it is carried up to the top of the bank, the top course oversailing at the back, and forms the fender.

These different systems of stone facing for banks have been tried on a scale sufficiently large to form a tolerably correct judgment as to their expense and efficiency. The last section fig. 17, is evidently the best, but the cost is very high, and the same may be said with regard to section fig. 18, besides neither of these two last sections have the advantage of deadening the effects of the wave. The section ultimately adopted is that shown in fig. 10, its cost is 2*s.* 1*d.* per yard forward.

The Union Canal.

This canal has a breadth of 40 feet at the top, and a mean breadth of 37 feet on the line of the water surface, the depth below this line is 5 ft. 3 in. and 4 ft. 6 in. to 2 ft. 3 in. more to the top of the banks. This section, as will be presently described, is more favourable for passage boats than the section of the Forth and Clyde Canal.

It is on this canal that stone facing have been adopted to the greatest extent since the establishment of passage boats, and on which circumstances have been most favourable for this description of traffic. The same systems have been tried as on the Ardrossan and the Forth and Clyde Canals, but the nature of other materials on the spot have caused the adoption of a different system for those canals, more simple in operation and better adapted to effect the end proposed. The section fig. 11, shows the stone facing of the bank, it is nearly similar to those of the Forth and Clyde Canal fig. 10. On the towing-path bank there is however a slight batter or inclination given to the facing, and also on the opposite bank are laid large pebbles placed irregularly to a certain thickness, instead of rough stone.

A considerable length of bank is faced with stone as shown in section fig. 18, of the Forth and Clyde Canal, and another system has been tried similar to section fig. 19. But the facings adopted and generally followed are those shown in sections figs. 20 and 21. In section fig. 20, stone slabs of different lengths, from 28 to 32 inches wide, and 2½ to 3 inches thick form the facing, they are sunk into the clay puddle of the bank: it was found that the upper part of the facing was not sufficiently firm, consequently another narrow slab was laid on the top horizontally, as shown in fig. 21, which prevented the pressure of the earth against the top of the facing, and made a base for the turfing of the slope of the fender.

The facings of the towing-paths on the banks of the Union Canal, between Falkirk and Edinburgh, have been made the same as the two last methods just described, nearly throughout the whole length, and in some cases the opposite bank also. This description of facing has an excellent effect, both as to appearance and as to its operation on the waves of the canals. The joints being well secured, no water can get in to injure the bank, and this plan which gives the best appearance to the work, is in reality the most economical, the cost being only from 2*s.* 6*d.* to 3*s.* per yard forward, while the work in fig. 11, costs from 3*s.* to 4*s.* The reason for this cheapness is the abundant supply on the spot of a slaty stone well adapted for the purpose.

Canal de L'Ourcq.

The canal de l'Ourcq had already suffered very much from the action of the water, on the two banks between la Villette and Claye, when it was proposed to run passage boats upon it. It therefore became necessary to repair the banks, and the expense of stone facing on the English plan, and the want of good materials rendered a distinct course necessary. The canal company having a large quantity of brushwood and cuttings, wished to have a trial made to protect the banks with fascine work, as in section fig. 5. Stakes of oak 4 inches thick were therefore placed at every twenty inches distance, and driven into the ground 2 ft. 3 in. to 3 feet deep, and fascines placed behind them. It was soon found, however, that the fascine work was ineffective, as the water got in during the undulations, and on retiring carried away the earth. The fascines have therefore been removed, and oak planks laid behind the stakes, as shown in fig. 14. This plan, there is every reason to believe, will prove cheap and work well.

On other parts of the works another plan, as shown in figs. 2 and 7, has been adopted, like that on the Ardrossan and Forth and Clyde Canals. The works however get on slowly on account of the difficulty of finding stones large enough.

RAILWAYS BILL.

Since our last number, Mr. Labouchere's bill has made farther progress, and such is the want of effective opposition, that it would doubtless have passed through all its stages by this time, had not Sir Robert Peel interfered to get it referred to a select committee. From this committee, however, we expect little good, although Sir Frederick Smith is said to have been sorely discomfited in his examination by Sir Robert Peel, when his incompetency was shown so fully as to have been convincing to the minds of unprejudiced persons. Mr. Labouchere felt this, and was in the greatest possible rage, so that, to cool himself, he endeavoured to harrass several of the witnesses in such a manner as to call down the remarks of the chairman, although he effectively succeeded in frightening some parties.

The opposition, as it is called, which is now being carried on, proceeds from a committee of the delegates of boards of directors, who have overstepped their powers, and are disunited among themselves. Several of the chief of the delegates are, indeed, publicly charged with giving underhand support to the Government plan, while they throw every obstacle in the way of those who attempt to carry on the opposition in earnest. From such parties no good can be expected under any circumstances, and we need scarcely say that they are totally unfitted for defending the interests of the engineers, which, by the Government attempts, are the most threatened. The delegates are all from railways which have their bills, and most of them from finished lines. Chairmen of companies of course care nothing about how the engineers are likely to be interfered with, neither do the directors of finished railways care one straw about what measure is meted out to the projected lines; on the contrary, they would willingly give every aid, as they have shown, towards casting obstacles in their way. Narrow or broad gauge, six or four wheeled engines are nothing to directors, but they are great things to engineers, who are not likely to be best pleased with the exercise of their profession, when it is to be ruined by being placed under the tampering knick-knackery of a railway inspector, who entered on his duties ignorant of the works he was called on to inspect, and who has distinguished himself ever since by his disposition to foist his own crotchets, in opposition to the experience of other men. Although Sir Frederick Smith does not claim the power of meddling with engineering details at present, he evidently reserves it, and we have, in the report of the horse marine steam-boat inspectors, a pretty good inkling of the kind of interference which they ultimately look forward to. We have seen one difference of opinion already, and we ask what farther we have to expect from the forbearance of the government jobbers. A pretty pass affairs have come to in the profession, when the Stephensons, Brunel or Locke, are to knuckle down in their own department to a military engineer, to come like petty schoolboys and recite their tasks to a dabbler in the art, themselves have created. The statues of Smeaton, Watt and Telford, may tremble on their pedestals at this insult to their successors. What tribunal would be called upon to decide if men at the head of the law or medical profession entertained a doubt? Is there any tribunal? We think there is none. The government would think otherwise; the course they would adopt would be to send the Lord Chancellor or Lord Denman, Sir James Clarke or Sir Henry Halford, to some one in the lowest ranks of their professions. We consider the interference of the government with engineering, as a gross insult to the profession. They would not refer the fortification of Chatham to us, why then should military engineers be sent to interfere with railways?

It is the eleventh hour, but we call again on the engineers to come forward, and to resist these encroachments ere it be too late. Government cares nothing for their interests, neither do railway directors, so that the only way engineers have of protecting them, is by protecting them themselves. The injury threatened by the government is very great, no one can tell the greatness of its extent, for one successful attack upon the liberties of the profession cannot fail to lead to farther inroads. Let the engineers do as the marine engineers did last year, and as they mean to do this, unite, and we have no doubt that the jobbers will be defeated. If, however, they like to be under the dominion of the one-tailed bashaw in Whitehall, they will remain supine and allow themselves to be sacrificed. We call upon them therefore to lose no time in organizing an opposition. The Institution of Civil Engineers we feel are particularly called upon, and we consider that they will grossly neglect the interests of the profession if they do not immediately send a petition to both Houses of Parliament, praying that no government interference with the profession may take place. The engineers generally should also meet, and send similar petitions, and a committee should be formed to oppose the bill at its future stages.

ENGINEERING WORKS OF THE ANCIENTS, No. 3.

MINES OF THE THASIANS.—SIPHNIANS.—ATHENIANS.

Continuing our extracts from Herodotus, we find that the Thasians derived considerable wealth from their mines. From those of gold at Scaptesyla they obtained upon an average eighty talents; Thasos itself did not produce so much; but they were on the whole so affluent, that being generally exempt from taxes, the whole of their annual revenue was two hundred, and in the times of the greatest abundance three hundred talents. It may be observed that many of the Greek states derived considerable revenues from mines, which admitted of the application of slave labour on a large scale. So with some of our modern states mining and mining monopolies are important sources of income. Of the Thasian mines, Herodotus remarks, that he had seen them, the most valuable were those discovered by the Phenicians, who also were engaged in the Cornish tin trade, and in working the mines of Spain. The Phenicians are stated by our author to have first made a settlement on the island under the conduct of one Thasus, and to have named the island after him. The mines so discovered were between a place called Ænyra and Cœnyra. Opposite to Samothracia was a large mountain which by the search after mines was effectually levelled, from which it is evident that the working was surface working. The Thasians also, according to the testimony of Thucydides, had some valuable mines on the coast of Thrace. If the mining of the Thasians was confined to surface-working, it could scarcely be from want of a knowledge of other modes, as we shall see by the example of the Samians that tunnelling was carried on upon a large scale. The Siphnians were also a mining people, their soil producing both gold and silver in such abundance, that from a tenth part of their revenues, they had a treasury or cash-box, as we should call it, in the general bank of Greece at Delphi, equal in value to the richest which that temple possessed. Their power was consequently considerable, and they were at one time the richest of all the inhabitants of the islands, although their territory was but small, being one of the seventeen small islands opposite Attica, called the Cyclades. This isle is now called Siphanto, and although it no longer has mines of gold and silver it still has plenty of lead, which the rains discover. The Siphnians every year made an equal distribution among themselves of the produce of their mines, as did the Athenians of that of the silver mines of Attica. In allusion to stream-works, Herodotus says that the Indians obtained great abundance of gold, partly by digging, and partly from the rivers. Of the Ethiopian gold our author speaks, but does not say how it was obtained. Tin is mentioned as being obtained from the Cassiterides, supposed to be the Scilly Isles, of which Herodotus says that he has little information.—The north-west of Asia is represented as abounding with gold, but how it was obtained was not known. This passage might refer to the mines of the Ural.

WORKS OF THE SAMIANS.—TUNNEL.—AQUEDUCT.—MOLE.—ENGINEERS.

The Samians were distinguished among the Greeks for their engineering monuments, for which very reason Herodotus says that he was particular in his account of those islanders. Of these works, remains to this day exist. Through a high mountain they are said to have cut a passage, seven stadia (about a mile) long, eight feet high, and as many wide. By the side of this was a canal or aqueduct three feet in breadth, and twenty cubits, according to our author, in depth, but in this there must be some mistake.—In this canal pipes were laid conveying to the town the water of a copious spring, supposed to be that of Metelinous. Another work is the Mole now forming the left horn of Port Tigrani. According to Herodotus, it was two stadia or more in length, and twenty orgyiæ or cubits in height. The engineer of the tunnel was Eupalinus, the son of Naustrophus, and an inhabitant of Megara.

TRENCH OF THE SCYTHIANS.—WALLS—BRIDGES.

The descendants of the slave population having revolted against the Scythians, intersected the country with a deep trench, supposed to have separated the Crimea from the mainland. In the time of the Emperor Constantine Porphyrogenitus this was filled up, it must however have existed for a long period. In Scythia are also mentioned bridges and walls constructed by the Cimmerians.

Polybius.

CARTHAGINIAN ENGINEERING.—BRIDGE OVER THE MACAR.—NEW CARTHAGE CANAL.—GOD OF MINING.

From Herodotus we come to Polybius, but it is to be regretted that the latter has rather applied himself to accounts of political intrigues than the descriptions of the physical features of the countries on which he writes. From him therefore we are enabled to glean but little information, and that of a most discursive character. He gives several hints showing us the capacity of the Carthaginians for engineering, but he has not entered into those explanations which would have come with weight from him as an eye witness. The passage of the Alps, by Hannibal, is sufficient to prove the skill of the Carthaginians, but we have too vague a description of the mode of proceeding to allow us to profit by it.

In the 1st book chapter 6, a singular account is given of a bridge near Carthage, which was laid over the Macar, a deep and rapid river, scarcely fordable in any part. This was the only bridge on the river and formed one of the passes to Carthage. On it Polybius states that a town was built by the soldiers and used as a garrison. The roads in the neighbourhood of Carthage were mostly made by great labour.

In their military operations the Carthaginians were well accustomed to pass rivers, instances of which we have in the course of Hannibal's expedition.—His passage of the Rhone belongs rather to military tactics, but there is one point to which we think it necessary to allude, as it may be of interest to our bridge engineers. Having formed a me of large boats across the river, he made use of them as a coffer-dam or breakwater, and under the shelter of them, passed over the troops in canoes, and swam over the horses, which were guided alongside of the vessels by men stationed on board of them.

At Nova Carthago (Carthagena) in Spain, one of their principal colonies, we again find traces of their engineering works, between the lake and the sea they cut a narrow navigable canal, and across this there was a bridge used by carriages and beasts of burden. In the city, one of the hills was dedicated to Aletes, who is said to have obtained divine honours, from having first discovered the silver mines, which were extensively wrought by the Carthaginians in Spain.

GREEK ENGINEERING—BRIDGES—PHŒNICE—PSOPHIS.

In Epirus we find mention of a bridge, which seems to have been after the fashion of that at Babylon, mentioned in our first article, and to have been of a class common among the ancients. This was at Phœnice, and had piers of stone with moveable planks laid upon it. At Psophis in Arcadia a bridge is mentioned over the Erymanthus, a great and rapid stream.

CAUSEWAY—AMBRACUS.

Ambracus in Etolia is described as a fortress of considerable strength situated in the middle of a marsh, and secured by a wall and outworks It was only to be approached by one narrow causeway. It was besieged and taken by Philip king of Macedonia, who carried causeways through the marsh.

SIZE OF FORTS.

Speaking of Tichos, a fortress near Patræ, Polybius says that it was of no great size, being not more than a stadium and a half in circumference, so that it might have sides of eighty yards in length.

ENGINEERS.

Among the supplies furnished by the Rhodians to the Sinopeans in their war against Mithridates,* engineers are mentioned, and military engines.

REBUILDING OF RHODES.

On the destruction of Rhodes by an earthquake, large supplies were sent by the allies of that city in order to enable them to rebuild it. Among these supplies Ptolemy, king of Egypt, sent forty thousand cubits of square pieces of fir; a hundred architects, and three hundred and fifty labourers. Antigonus sent them ten thousand pieces of timber, that was proper to be cut into solid blocks from eight to sixteen cubits: five thousand planks of seven cubits; three thousand weight of iron. Seleucus his father sent ten thousand cubits of timber.—Other parties sent in the same proportion.

Building materials seem to have been considered as of great value, for in case of the sacking of towns the timber and tiles were frequently carried off.

EPISODES OF PLAN.

(Continued from page 71.)

Although they may seem to betray a consciousness of the weakness of our cause, upon the principle of *qui excuse, accuse*, we have considered the preceding remarks necessary, in order to combat the opposition which the system we would recommend is likely to encounter. But it would be a positive weakness on our part, were we to assume a deprecatory and apologetic tone, as if we had misgivings of our own, and accordingly threw ourselves entirely upon the indulgence of our readers, for presuming to bring forward what its novelty alone may be thought to condemn. The starting matters altogether so new is in itself an act of presumption, if merely because it is a tacit reproach upon the indolence, the indifference, or ignorant carelessness of those, who, having had the opportunity, have never touched upon, or called attention to them; consequently sinning as we do to that extent, we may dispense with what would be as troublesome to ourselves, and as impertinent towards our readers, as it would be useless—namely, any affectation of modesty.

Be it said that opportunities for applying any striking combinations of plan, even in the way of episodical parts in a building, are of rare occurrence, that ought to be a *raison de plus* wherefore every thing like an opportunity should be eagerly caught at, and turned to the utmost account. So far from which being the case, it appears to be especially shunned. There are some hundreds of seats and residences throughout the country, from which, putting them all together, hardly half a dozen fresh ideas are to be obtained. That they may be "goodly houses,"—well built, and containing well proportioned, expensively and luxuriously furnished rooms, is not denied. Their plans may be perfectly unexceptionable as regards comfort and convenience,—free from aught amounting to a fault, or even to a blemish, nevertheless as insipid and uninteresting as possible. Look at the majority of the plans given in Richardson's Vitruvius Britannicus,—which, it may be presumed, are rather above than under the average: do they offer a single happy architectural point worth studying? Yet in houses of the class there shown, some merit of that kind might reasonably enough be expected. The chief lesson to be derived from them is that both their employers and architects themselves are satisfied with the very first ideas that come *to hand*—and the hand seems to have more to do with such matters, than the mind. Exceptions, it is true, are to be found; yet they are merely the *rari nantes in gurgite vasto*;—which circumstance, however, much as it is to be regretted in itself, has its convenience, because all the examples of that kind might be collected together within a moderate compass: and it has frequently struck us as rather singular that no one should hitherto have brought out a publication devoted entirely to a series of studies of interior architecture, elucidated not only by plans and sections, but perspective views also, for the purpose of showing effects. Of course we would have only the very cream served up, without a particle of that "thrice skimmed sky-blue," which architectural caterers are too much in the habit of imposing upon their customers.

Were it properly got up, some such work as what we have just pointed out, would be found eminently instructive, particularly if accompanied by *pentimenti and variations* of the plans (in wood-cuts), showing the same general ideas differently modified. It is true, something of the kind may even now be picked up out of architectural publications: but then it is not from such as are to be met with in a moderate collection, or as are likely to fall in the way of students. Neither are such subjects satisfactorily elucidated, when they occur merely as parts of general plans and sections, in which latter far more is sometimes left unexplained and doubtful, than is actually shown. It may be said, and very truly so, that the want of any work of the kind has not been felt, or else we should have had not only one, but a number of them ere now, as in all such cases supply invariably keeps pace with demand. Yet, if this cannot be disputed, it seems to us only an additional proof of the utter disregard paid to the subject itself; as if any thing would do for interior architecture, and that nothing more is required in the way of designing than to be able to draw the doors, chimney-piece, and cornices of the rooms in a section. An architect, it would seem, requires no instruction for designing the interior of a building, except what he can gather from his own observation and practice; positive lessons and studies for the purpose, are quite unnecessary. There he may safely be left entirely to his own guidance; although, if such be the case, we do not see, wherefore so many finical rules should be deemed necessary for even the most trivial circumstances in external architecture,—more especially as those petty rules are after all little better than impertinences, for those who are worthy of the name of artists are guided by something better, while those who are not, blunder on by help of rules, pretty much as they would blunder on without them. Hardly can it be said that there is less occasion for the student's directing his attention to interior arrangement and design, than to exterior architecture, there being, according to the doctrine of chances, quite as much probability that he may have at least one opportunity of displaying his taste and ability in planning and decorating a moderate sized yet recherché residence, as that he will ever be called upon to erect a palace, a senate-house, a cathedral, a museum, or in short any one of those *pleasures* upon which academical students are set to work their wits before they are capable of producing a single new idea on a moderate scale.—To be sure there is less study required for producing something catching on a large scale, where the "lion's-hide" pompousness of the subject conceals the inanity and poverty of the conception.

Probably the remarks we have just made, will be considered quite irrelevant and impertinent; and that they are somewhat ungracious we admit—would to Heaven! they could be proved to be utterly unfounded and unjust!—But of introductory observation our readers have by this time had enough—more than may be altogether palatable: it behoves us therefore, now to come at once to our professed subject; which is, indeed, one both so new in itself, so complicated, and of such extent, as to render the task we have undertaken rather an embarrassing one. We do not pretend, however, to treat it systematically, proceeding gradually from the simplest elements of plan, to the most varied combinations of them; but shall merely in the first instance, enumerate some of the leading circumstances by which different con-

* Polybius book 4, chap 5

binations may be obtained, and then exhibit some detached *Episodes*, and individual instances. Hitherto, *Plan*—by which we mean not only the outline of the floor, but that of profile and section likewise—has been allowed to exhibit scarcely any variety, effect being almost exclusively limited to that kind of it which arises from material, colour, and decoration. Accordingly if it can be shown that there are other sources of variety, it becomes evident that there is far greater scope afforded by interior architectural composition, than where novelty of design consists in nothing more than substituting one order of columns for another, or something else of that kind, without any novelty whatever in regard to arrangement, shape, and proportions in the ensemble.

Of course where a room is a simple square or parallelogram in its plan, there can be no combination; yet as soon as we proceed a step further various combinations may be obtained. Still we choose to limit ourselves in nearly every case to the simplest and first step: for if it be required to give rather more than ordinary architectural character to a room, it is usually done by putting two columns towards each end, so as to divide it into three compartments: and that being done we seem to have fairly got *au bout de notre Latin*. Let us, then, take no more than a triple arrangement of plan, and show some of the combinations that may be obtained from it, distinguishing the divisions of the plan by the terms Centre and Ends; and it will be less troublesome to ourselves, and more intelligible to our readers, if we give them in the form of a mere list. First then, in regard to plan, we have the following varieties:—

Centre and Ends all rectangular, equal in breadth, and differing only in their relative proportions.
Centre wider than Ends.
Centre narrower than Ends, or the Ends *expanded*.
Centre rectangular, Ends semicircular or curvilinear.
Centre circular or polygonal, Ends rectangular.
Centre a square or parallelogram, Ends octagonal, hexagonal or other form of polygon.

Secondly. In regard to Profile or Section:—
Centre and Ends, of uniform height and with flat ceilings.
——————— ditto arched.
Centre loftier than Ends, but with flat ceiling.
——————— and domed, or arched.
Ends loftier than Centre, and arched traversely to the latter.
——————— and domed.

Thirdly. In regard to arrangement of windows and mode of lighting:—
Centre and Ends all lighted from one side of the room.
Centre lighted from side, Ends from the extremities of the room.
Centre lighted from one side, and Ends from opposite one.
Centre lighted from side, Ends from above.
Centre lighted from above, Ends from side.
Centre and Ends all lighted from above.
Centre alone lighted, either from side or above.
Ends alone lighted, ditto.
Centre or Ends lighted not from ceiling but from windows at the sides, at a distance from the floor.

Without our extending this list any further, it will be evident that a vast number of combinations may be obtained, entirely independent of the innumerable differences arising from columns and other decoration, from dimensions and proportions, from colour and material. In fact every one of the modes above enumerated—and they are by no means all—affords as much or more scope for architectural design in other respects, than there is now by the single one which is almost invariably adhered to.

We have merely mentioned as one distinction that produced by lighting either the whole room, or one or more of its divisions from the ceiling; but then, that, too, may be effected in a variety of different ways. The light may be admitted through glazed coffers or panels (plain, again or coloured), through a dome, or through a lantern, which last admits of almost infinite variety of form and design. Lantern lights may not only vary in their plan,—be square, oblong, circular, octagonal, &c., but be ceiled above and have windows on their sides, or closed at the sides, and have the light transmitted through the ceiling, accordingly as either the design itself, or other circumstances may dictate.

It may be said—and that not unreasonably—the kind of room we have noticed, namely, one capable of being divided into compartments, is fitted only for a gallery or library of some extent. Still there are a variety of other combinations to be effected in rooms of a different class, by merely breaking their plans, yet without exactly dividing them into distinct compartments. Dining-rooms certainly admit of great architectural character being bestowed upon them, by a sideboard alcove, by which is to be understood something more than a mere shallow or *blank* recess—as it may not improperly be termed—which where there is any thing of the kind at all, is generally the *maximum* attempted, although in itself it is exceedingly little indeed.

(To be continued.)

ESTABLISHMENT FOR PROCURING MOULDS FROM MONUMENTS OF ART.

Sir,—The debate which followed Mr. Gillon's motion, cannot fail to raise the hopes of all who have the interests of taste at heart; and I hope that you will permit me, at this apparently auspicious time, to bring forward in your columns a scheme, which, although, if I may judge from the brief paragraph in a former number, does not meet your approbation in its original shape, yet if some other mode of operation can be devised, its object will, I feel convinced, have your earnest support. I allude to the formation of an establishment for procuring moulds from interesting monuments of art, and for diffusing casts from these at the cheapest possible rate, over the country.

The French have long possessed such an establishment, under the immediate patronage of government, and moulders are constantly employed in foreign countries, as well as in different parts of France, making moulds from monuments of art of every age, from the earliest times down to a late period. French moulders are to be found not only in the capital cities of Italy, but also in the ancient towns which offer so many interesting specimens of the arts of the middle ages. A few years ago, as I have already stated in a former paper, elsewhere, 11,000 dollars were spent in Florence alone, in making moulds which were afterwards conveyed to Paris. How advantageous the results of such a system! In Paris artists of every description may find specimens of sculpture from every statue and building with which they are acquainted. Architects may at a very small cost, in addition to their libraries, form museums, containing casts from portions of the buildings, the plans and elevations of which their books contain. Engravings however perfect, can convey but a faint idea of the graces of execution in architectural sculpture, and I think that the consequences of designing from these alone are sufficiently illustrated, in our cold, spiritless, and precise ornamental details.

I wish to see some such establishment as the French one in London; the subject has excited much attention in Scotland, and when I first brought it forward it was warmly taken up by many enlightened and energetic individuals; but objections were urged against it in London, although I have not been able precisely to ascertain their nature or extent. I believe that the apprehension of the creation of a monopoly, and the consequent injury to individuals who have already invested capital in casting was the strongest objection. I should like to know, how much capital is really invested in this branch of trade, and how many individuals pursue it, and how many good moulds they possess? of this I am certain that we have repeatedly been obliged to send abroad for casts, after vainly seeking them in London. It may be observed that this is not surprising, if we demand casts from works, of which it is most unlikely that casts should exist, but this has not been the case, the casts required have in most cases been such as *ought* easily to have been found in London. Your own Schools of Design are furnished from Paris, for with the exception of casts from sculptures in the British Museum, which are of the best quality, a few from foreign monuments of a very indifferent quality, and some from our national specimens of art, nothing is to be had in London.

I would here point out that there are difficulties in the way of procuring moulds from important monuments, which are insuperable to private enterprize. Government alone for instance, could procure a new mould of the Venus de Medicis. I feel convinced that although the Grand Duke will not hear of a mould from this statue of statues, he would at once accord it, to the request of a nation preferred through the proper channel, to which he owes his possession of the gem. I have no doubt that established London sculptors would willingly give fifty guineas for a first cast from a new mould of the Venus, I have known twenty-five paid in Rome for a good cast of this statue; in this point of view it seems evident that such an establishment could not prove a very costly one to the nation, for however liberal its Directors ought to be to public galleries, and however cheap casts generally should be sold to effect the good anticipated, still first casts from rare and precious works should be disposed of to individuals on different terms. There are unquestionably numberless specimens of art of the highest value and interest, casts from which, could be procured only by government influence. I mentioned the deficiency in London of moulds from important monuments, I should imagine that the chief source of profit to your casters must proceed from their employment by living sculptors, and a National Casting Establishment whose object would be wholly different, and which would supply deficiencies which it is impossible that they can ever supply, could not prove so fatal to their interest, but on the contrary, by promoting taste, and exciting a love for such objects would prove a source of increased encouragement.

If the objections to a national casting establishment are insuperable, could not some other plan be devised? The object is a great one, a commencement might be made by making moulds from the finest works in Great Britain, and then we might proceed to foreign countries: casts should be sold at as low a rate as possible, provincial galleries and schools of design should be supplied free of charge. I should hope to see every workshop a museum. The more we can accustom our lower orders to the contemplation of beautiful forms the better, and what better or cheaper means can be devised? I go further, I think it possible to erect casts in appropriate galleries of many architectural monuments, the sizes of which do not offer any insuperable difficulties. The student might measure, and delineate the Choragic monument of Lysicrates, or the arch of Titus, without going beyond London. Casts of many Gothic shrines and monuments might be put up in all the splendour of their full proportions, and where the gigantic size of any building utterly precluded such an idea, still casts of entire entablatures, capitals, and portions of shafts might be erected. What a magnificent spectacle would such a gallery offer, which contained a series of casts from early monuments down to the architecture of the last age of original invention.

I have alluded to the interest this subject has excited in Scotland, and I may truly say in England also. Learned societies, noblemen, members of Parliament, and other influential gentlemen, besides some of the most talented artists now living, have approved of this idea. I trust, Sir, that the day is not far distant when we may hope to see it adopted and followed out under some good working form, and I hope that those who have studied the subject will favour all who are interested in it with their suggestions.

I am, Sir,
Your very obedient servant,
Charles H. Wilson.

8, Northumberland Street, Edinburgh.
13th March, 1841.

[If such an establishment were confined to obtaining and moulding new works, it would, as our talented correspondent says, be most advantageous: but if, as the plan was originally proposed, it were to be a general public factory, we think that it would be of no good, but, on the contrary, productive of harm.—Edit.]

CANDIDUS'S REMARKS ON THE LECTURES OF THE PROFESSOR OF ARCHITECTURE.

Sir.—Will you allow me to offer a few remarks on the last Fasciculus of Candidus, in which he makes so free with the Professor of the Royal Academy. I would submit that he has misunderstood him on an important point in his lectures, and given him credit for a "bigotry" of which he is in nowise guilty. The Professor said nothing in disparagement of "Gothic Architecture," unless indeed his remarks on the beauty of a series of Gothic windows, on the good effect of Gothic spires in a level country, on the excellent construction and beautiful proportion of Salisbury Cathedral—on the elegant fret-work and tracery of a Gothic window, &c., may be taken in that signification. All that he said which could be interpreted as unfavourable to the style was, that he considered the revival of Gothic architecture as a fashion of the age, and like other fashions, one that passeth away.

Now if we examine the history of any age or country we shall observe a very marked correspondence between the character of the architecture, and the literature, habits and condition of the people, and that these have always progressed together. For example, the architecture of Greece clearly evinces itself to have been that of a highly refined people, possessed of a limited extent of territory, and whose principal wealth was in the hands rather of the state than of individuals, and therefore lavished almost exclusively on public buildings;—a people ambitious of bringing every thing they attempted to the utmost perfection. Their style of architecture was in all its main features adopted by the Romans, but received from them such alterations as were necessary to accommodate it to their peculiar circumstances, those of conquerors of the world; the extent, variety and magnificence of their structures were increased to a degree unknown before or since, and the exquisite delicacy of the Grecian detail in a great measure disregarded—their endeavour being to strike *every* beholder with awe—while the Greek architects sought rather to captivate the admiration of men of a refined and cultivated taste.

Taking these as examples, and I feel assured that the same reasoning may be applied to the architecture of all countries, it would seem very doubtful, whether a style which has arisen naturally from the wants and habits of one nation, could with advantage be assumed by another whose state of civilization and feeling are totally different;—and I must acknowledge that I think classical architecture harmonizes more nearly with the habits of the present age than does the Gothic. The Greeks and Romans had reached the highest point of luxury and refinement at the period at which they erected those buildings, of which the remains form models for our imitation—while on the contrary civilization has been regularly proceeding in countries where Gothic architecture was practised from that time to the present. The Romans again had communication with all parts of the known world, in almost as great a degree comparatively as we now have, while our ancestors of the middle ages had but few opportunities of enlarging the scope of their understanding, by their researches in foreign countries. The mechanical arts have since the middle ages made gigantic strides towards perfection, insomuch that many of them which have become necessary to our comfort, are found inapplicable to the peculiarities of Gothic architecture. Mullioned windows are more suitable for casements with small panes of glass, than for the large squares now in use. The introduction of slate renders the high pitched Gothic roof unnecessary, and every architect must have experienced the difficulty, nay impossibility of introducing joinery and interior finishing generally, of good Gothic character. Another great proof of the incongruity of the style with the general habits of the age, is the difficulty of persuading persons to adopt it who are not possessed of an antiquarian taste—while the expense of producing architectural effect, is with the mass the only objection to the Italian or Grecian styles.

There is still another point, and perhaps the most important of all, and that is the object of the architect where he designs in the Gothic style, compared with his object when he employs the Grecian or Roman—in the former case it is *imitation* that he aims at, in the latter *invention*. Thus the great work of excellence in a modern Gothic building is that it should be mistaken for an ancient one, the architect being governed by authority in all his details; and a departure from this rule is the principal cause of all the bad Gothic with which the eye is offended in every part of the country. This is not so much the case with Grecian or Roman—from the nature of the style a greater regularity is necessary, certain proportions have been determined on for the principal members, and as long as these are preserved, there is no restriction on any novelty that may be produced in accordance with them. This last objection applies as much to ecclesiastical as to domestic architecture, which I admit is not the case with those first stated.

If these views are correct, it is very possible to discourage, with the Professor, the indiscriminate revival of the architecture of the middle ages, without in the slightest degree adopting the prejudices of Evelyn, in considering it "monkish and gloomy, and devoid of all harmony and proportion," or those of Morris,* who looked upon the "boasted piles of Salisbury and Westminster, &c., only as so many monuments of wanton and tasteless expenditure;" or those of Hamilton,† who looks upon it as the offspring of the dark ages of Gothic barbarism.

I am, Sir, &c.

HARBOURS ON THE SOUTH EASTERN COAST.

Sir—As you have done me the favour to insert several communications of mine relative to bars and other nautical matters, I take leave to request that you will give publicity in your next Journal to the following observations, suggested by the motion of the hon. member for Dover, E. A. Rice, Esq., for a select committee of the House of Commons on the state of the harbours on the S. E. coast, to which the report of the commission of 1840, on the state of the harbours on that coast, should be referred. This motion was negatived by a majority of 64 in a house of 140 members.

The mover and seconder of the motion re-stated what has been often urged on the public by your Journal, *i. e.* that on the entire extent of coast from the Thames to the Isle of Wight, there is not a harbour of refuge either as a port of rendezvous for the navy, or for the protection of our merchant vessels in adverse winds, and stormy

* In a small work on the proportions to be observed in architecture. By R. Morris, 1739.

† Letter to the Earl of Elgin on the new Houses of Parliament. By Wm. Hamilton, architect, 1836.

weather. This, too, is on a part of the coast at a short distance from that of France, the government of which has caused essential improvements to be effected in various ports opposite to the English shores, and to which their steamers can resort in time of war, much to the annoyance and injury of our commercial marine, while our shores have no such port or protection.

That part of the coast and Channel here referred to, is navigated by a greater number of valuable ships and cargoes than any other channel in the world, except the N.E. coast; consequently the loss of valuable property (£5,000,000 *annually*, and the more valuable human lives, 100,) is in the proportion to the number of vessels passing up and down the British Channel, losses which are occasioned by the lack of harbours of refuge, (as a committee of the House of Commons have determined,) and yet the legislature of the greatest of all naval and maritime commercial nations has negatived a proposition of such vital importance to the safety of the navy, and the protection of our merchant vessels and their crews; an object of primary and vital importance.

The Right Honourable the Chancellor of the Exchequer was pleased to observe, in his opposition to the motion, "as regarding the commission he did not hesitate to say, that from the character of those composing it, and their fitness for the task assigned to them, no committee of the House of Commons could have the same weight with the public." But the public might have had much more confidence in the opinions which would have been elicited from scientific and practical men, whom such a committee would examine. The right hon. gentleman subsequently said, "With respect to the report of the commissioners, one part of it was somewhat doubtful;" (a *most important* part;) "Three different plans were proposed, and the expences were estimated at £6,000,000: now he *doubted* whether means could not be adopted for effecting the purpose at a much less expense."

In a petition which I had presented to the House of Commons in the session of 1840, I endeavoured to show that the sites selected, and the plans recommended by the commissioners for the construction of three refuge harbours, could not obtain the proposed advantages. *i.e.*, eligible harbours of refuge, with safe ingress and egress *at all times*; and, that much beneficial improvement might be effected at Dover, and that all that could be obtained in that vicinity was attainable at a cost of £3,000,000.

The estimated cost of constructing a harbour at the North Foreland, at Dover, and at Beachy Head, as contained in the report referred to, emanated from the engineers who were of the commission: the accuracy of these estimates is doubted by the Chancellor of the Exchequer. If those gentlemen were in error on that part of the case which immediately belongs to their department, no correct information ought to be expected from them on the nautical part of the subject, *i.e.* an eligible site for construction, and the best method of forming the entrance and departing passages.

It is essential to remark here, that the harbours of Lowestoft, Dover, Hartlepool, &c., demonstrate two important facts, that the application of sluicing or scouring water is a most fallacious principle to pursue, either in constructing or in improving harbours, and that the impetus of the wave and the influence of the wind and tides, are not to be controlled by mathematical calculations; harbours and bars are affairs exclusively to be managed by men of long nautical experience, possessing local information; but other parties being consulted give cause to the many failures in attempts to improve and construct harbours, and the immense loss of money in such attempts: *e. g.* Lowestoft, an entire failure, with the loss of an expenditure of about £100,000, now offered for sale by her Majesty's loan commissioners for £17,000. Dover, after a large expenditure—bar accumulating. Hartlepool—sluices injurious, and therefore discontinued.

The competency of the other gentlemen of the committee is not proved by their previous practical knowledge of the S. E. coast, for if they have at any time navigated that part of our seas, it was, no doubt, under the direction of pilots. The report bears testimony that to the places and principles for constructing harbours on the S. E. coast, as recommended by them, there is an insuperable objection.

Regretting that a subject of so much importance should have been so long neglected and again procrastinated, a subject brought before a committee of the House of Commons in 1826 and 1827, and again in 1836,

I remain, Sir,
Your's, &c.,
HENRY BARRETT.

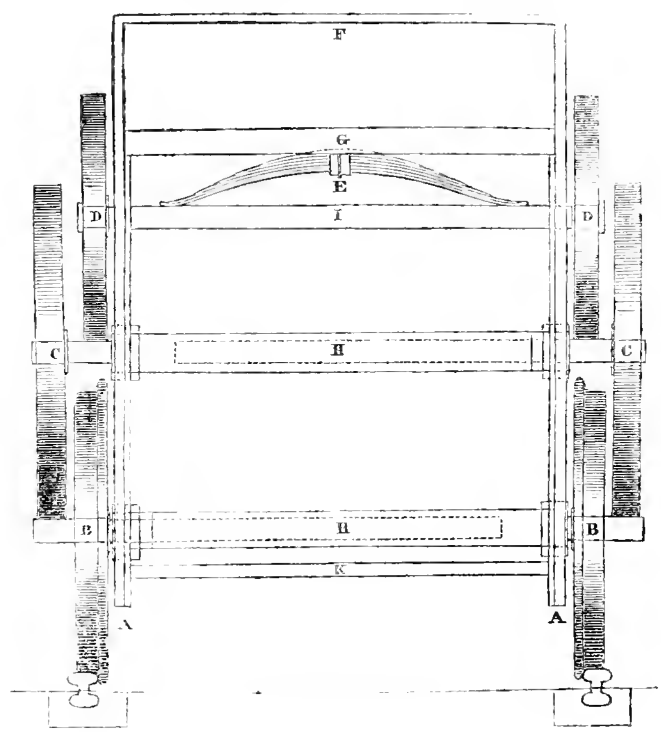
23rd March, 1841.

COLES'S PATENT SOCKET AXLETREE.

Mr. Coles the inventor of the Anti-friction Wheel Carriage described in the Journal vol. I, p. 107, has lately taken out a patent for an improvement in axle-trees for railway carriages, whereby one of a pair of wheels may turn without the other. It is well known that there is great friction between the flange of a wheel and the rails when working round curves, particularly if they be sharp ones; to obviate this evil, Mr. Coles has invented a socket axle-tree as described in the annexed engraving, whereby it will be perceived that either wheel may turn whilst the other is standing still, at the same time the axle possessing all the rigidity of one that is fixed to both wheels; by this arrangement the outer or off wheel when working round a curve can make a larger number of revolutions than the inner wheel, and when running on a straight line they will both make the same number of revolutions.

The axle-tree is thus formed, a hollow axle is carefully turned with a socket or tube nearly the whole length of the width of the carriage, into which is fitted the axle of the other wheel, this axle is carefully turned with a shoulder at each end three or four inches wide, the small vacuity between the shoulders, and also between the outer and inner axle-trees is filled with oil, which lubricates the rubbing surfaces of the axle.

Transverse section of a carriage showing the frame, axles and wheels, for working on common rails or roads.



A A, the frame; B B, the ground wheels, which are anti-friction; C C, the large anti-friction wheels; D D, working or friction wheels; E, the spring; F, top of carriage; G, upper cross stay; H H, axles working in sockets; K, the bottom cross stay.

Government Museum of Economic Geology.—The arrangements for the opening of this new institution are progressing but slowly, and nothing has yet been decided as to when it will be thrown open to the public. It occupies the two corner houses, Nos. 5 and 6 in Craig's-court, which have undergone extensive alterations for the purpose. In addition to several rooms which will be devoted to the arrangements of the cases and cabinets composing the museum, there is a well-stored laboratory for instruction in practical analysis upon the ground floor. A large and prominent part of the collection in the museum is the extensive series of specimens of stone obtained by the commission for investigating the best material for building the new Houses of Parliament. The depository for mining records, forming another branch of the establishment, is already rich in statistical annals and details connected with the mining industry of the kingdom. Each department will be open to the public on three or more days in the week under certain restrictions.—*Morning Post.*

RAILWAY STATISTICS.

[The following Tables have been compiled from Mr. Whishaw's work on the Railways of Great Britain.]

Table A gives the total lengths of railways, from which it appears that of 58 railways enumerated, 1699½ miles in length, 31 (measuring 319¾ miles) are under twenty miles in length, suggesting a great waste of capital in the management.

Table B gives the lengths of 58 railways distributed as single and double lines of railway, by which it appears that not more than a sixth are single lines of railway.

Table C shows the number of miles of single and double railways laid down upon each gauge for 1756 miles of railway, with the total of miles of single railway laid down on each system, giving a total of 3217¾ miles of single railway, of which 2544 are laid down on the common gauge, and 427 miles on the broad gauge.

Table D shows the number of miles of single and double railway, the stated number of miles of railway, and the number of miles of single railway laid down with each of seven principal forms of rails, according to the classification of Mr. Whishaw.

Table E shows for 2271½ miles of single railway, the number of miles of single and double railway, the total number of miles of railway, and the number of miles of single railway, of each kind of rail, with the total weight in tons. It thus appears that rails of nearly 30 different weights are in use.

Table F shows for 2271½ miles of single railway, the number of miles of single railway of each description of rails, with the weight in tons, and the proportion per cent. of each class. From this it seems that about a quarter or 516¾ miles of single railway have rails under 50 lb. weight. The total weight of rails for 2271½ miles of single railway is 204,412 tons, and if we take the remaining portion of railways at the same average, we shall have a total of 309,604 tons of iron consumed as rails.

REMARKS ON THE CENTRAL FORCES OF BODIES REVOLVING ABOUT FIXED AXES.

By Joseph Martin, M.D.

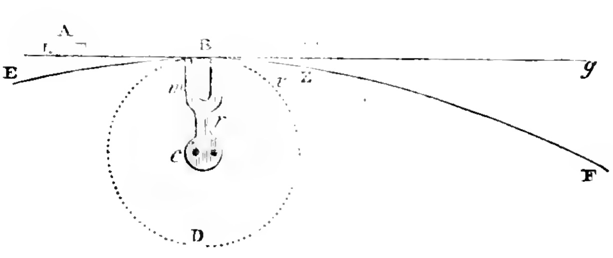
(From Silliman's American Journal.)

The theory of curvilinear motion may justly be considered one of the most important and interesting subjects connected with the physical sciences. It explains the motions of the heavenly bodies, and, by unfolding some of the grand phenomena of nature, makes them applicable to the most important and useful purposes of life. It has accordingly engaged the attention of the greatest philosophers for centuries, who have, by means of the most searching analyses, not only pointed out the slightest irregularities of those bodies which compose the great planetary system, but have discovered the causes of the seeming aberrations, and given satisfactory explanations of them. And yet it would seem that the most simple case of "central forces," the rotation of a heavy body about a fixed axis, has been in some measure neglected, or at least, treated as a subject of too little importance, either in a theoretical or practical point of view, to deserve more than a passing notice.

To explain the motions of the heavenly bodies it has been found necessary, by means of mathematical reasoning, to determine the ratio of attraction and original impulse, or projectile force, and to show the effects of their separate and combined operation. In this way the part that each of the three forces, the projectile and the central, perform in producing and preserving the motion of a planet in its orbit, is clearly defined; as well as the results that would follow if either of the last should cease to act. But the ratio of the forces which act upon a body made to revolve about a fixed axis, and the nature and extent of their separate or combined action, have not been distinctly shown. In other words, it is believed that the relative proportions of the moving power, and the forces that it produces directly and indirectly—the manner in which the central forces are excited—and the combined operation of all the forces upon a body whilst revolving and when projected, have not been satisfactorily explained.

It is not intended, however, at present to enter into an investigation of the subject upon principles purely dynamical, but the object of these remarks is to show by mathematical reasoning, founded upon experiment and familiar examples, that the power employed to revolve a body about a fixed axis is wholly expended in giving velocity to that body in the direction of the circle, and that, consequently, the central forces must be excited in obedience to a law of nature; and, in the second place, that the moving and excited forces act in conformity with the principles of "the composition of forces."

Fig. 1.



If the bar of soft iron m, fig. 1, be prepared as a horse-shoe magnet and secured in a proper manner to the rod r, working horizontally on an axle at c, it may be connected at pleasure with a galvanic battery, by means of its wires and the usual arrangements of cups containing quicksilver, at the centre. The iron bar A, of a suitable size and description, moving with a given uniform velocity along the straight line Ag, would be attracted at B by the magnet, if it were connected at that moment with the galvanic battery, and would be made to move in the curve Br of the circle BD, but in virtue of its inertia it would, in the absence of friction and atmospheric resistance, continue to move in that circle with the same uniform velocity. For the deflecting force being independent of the projectile force, and acting at all times in the direction of the radii of the circle, it cannot in any respect increase nor diminish the original velocity of the bar. And for the same reasons the force with which the bar is moving in the circle can have no influence upon the deflecting force. But a body moving in a curve or circle is always found to be acted upon by a third force, which is opposite and equal to the deflecting or centripetal force; and as there cannot be an effect without a cause, this third force must either be derived from one of those mentioned above, or their resultant—or from some other source. Supposing the circle BD, in which the bar moves, to be one foot in diameter, and the velocity of the bar to be 25·14 feet per second, or at the rate of eight entire revolutions in a second, its centrifogal velocity would be $= \frac{v^2}{2r} = \frac{25{\cdot}14^2}{1} = 632$ feet per second, and its centrifugal force $= 39$ lb. its weight being one pound, v representing the velocity in the circle, and r its radius; for if a be the weight of the bar, g equal to $32\frac{1}{12}$ feet, and x the force required, then $r : \frac{v^2}{g} :: a : \frac{v^2 a}{gr} = x = \frac{25{\cdot}14^2}{16} = 39$ lb.* But the force in the circle $= \frac{25{\cdot}14}{16} = 1{\cdot}55$ lb. only, consequently the centrifugal force could not have been caused by the projectile force. And it is evident that it cannot be a part of the magnetic force, for it acts in a directly opposite direction; and it is equally evident that it cannot be the resultant of the other two forces, for then its direction would be to some point within the circle. The pressure from the centre of thirty-nine pounds must therefore have originated in some other way.

Such are the facts when the deflection from a straight line is caused by a centripetal force directed to a fixed centre of rotation, and the projectile or moving force is applied before the body is constrained to move in a circle. We will now stop the revolving rod r, leaving the bar A attached to m, by the magnetic force. If by means of a winch the same number of revolutions in a second be given to the bar that it had in the first experiment, the centripetal or magnetic force will perform the part of cohesion, and the circumstances in every other respect will be the same that would attend such a rotation if the bar were welded to m. Does the moving power, applied in this manner, directly produce the central force or immediately impart it to the moving body? or, in other words, is centrifogal force a part of the force employed to revolve the body? Without attempting to prove the negative of this question by minute mathematical investigations, which will be avoided as much as possible on this occasion, I will show by a reference to the familiar examples of the common sling and fly-wheel, that in a revolving body centrifugal force, whatever be its source, is much greater than the power necessary to give rotation to that body, and that it cannot therefore be directly caused by the moving power,—and then explain how it may be proved by a simple experiment.

It has been stated above that writers on dynamics have not clearly defined the operation of the laws of curvilinear motion on bodies revolving about fixed axes. One only of the many instances in which erroneous views are given by popular writers in noticing the subject of central forces, will be mentioned. In the Library of Useful Knowledge [London edition] a writer, after enumerating some of the wonderful effects produced by *accumulating force in the circumference* of a fly-wheel, remarks: "the same principle explains the force with which a stone may be projected from a sling. The thong is swung several times round by the force of the arm until a considerable portion of force is accumulated and then it (the stone) is projected with all the collected force.† By observing the facts we may discover how all this accumulation of force is produced by the strength of the arm. A stone, S, fig. 2, weighing one pound, secured to the end of a string rather less than two feet long, may be whirled in a circle of four feet diameter at the rate of two entire revolutions in a second. It is done by turning the hand in a small circle AB, about a moving axis of rotation. The velocity in the large circle $= 12{\cdot}57 \times 2 = 25{\cdot}14$ feet per second; and, as shown above, if S represent the weight of the stone, v its velocity, r the radius of the circle and x the centrifugal velocity, then $r : \frac{v^2}{64} :: S : \frac{v^2 s}{32r} = x = \frac{25{\cdot}14^2}{32 \times 2} = 9{\cdot}87$ pounds. The velocity in the circle being 25·14 its force in that direction is equal to 1·58 lb. ‡ and if we add 1·42 lb. for the weight of the stone and atmospheric resistance, which is more than sufficient, we have three pounds as the force with which it is impelled in the circle ST. To enable him to move the stone in the circle the operator has to *resist a force nearly equal to ten pounds, which urges his hand from the centre at every instant*

---

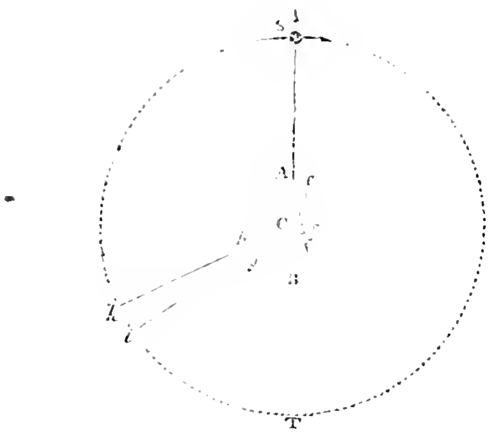
† Vol. I. p. 51. Art. Mechanics.

‡ Cavallo's Philosophy p. [illegible]

Fig. 2.

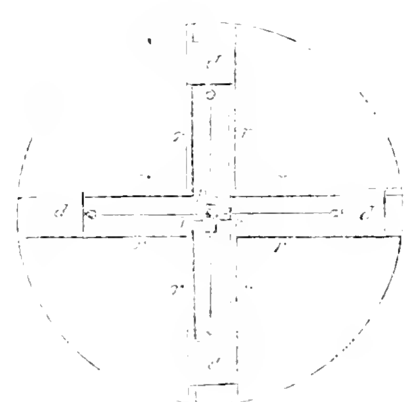


of time. He must therefore exert his strength at A in the direction of the resultant of the two forces with an effort which is equal in amount to their mechanical equivalent. If we make A*s* and A*c* in length proportionate to the forces 3 and 10 respectively, then the diagonal A*f* of the parallelogram A*sfc*, will show the direction in which he draws at the string, and $\sqrt{10^2 + 3^2} = 10{\cdot}44$ lb. will be the amount of force necessary to give the required velocity; of which, as shown above, two-thirds are expended in retaining the stone in the circle. Now it would be about as easy to show that a man can draw at a flexible cord secured to a stationary object with a force equal to 10 pounds, and at the same time press against that object, *by means of the cord*, with a force equal to six pounds, as to prove that the centrifugal force in this case is the immediate effect of the moving power. The man moves his hand in a small circle and pulls at a stone, nearly in the direction of the string to which it is attached, with a force equal to six times the weight of the stone, and yet, according to the popular belief, he not only imparts directly to it all the force with which it is projected, but dashes it off at right angles to the thong, as if it were moved at the end of a lever.

The thong of the sling, from what is said above, may be considered as in the place of an inflexible rod, the hand resisting the pressure that would act as a strain upon an axle at *c*; and if such a rod had a handle at A, the same effect might be produced. But it would cause great friction and strain upon the axle, and to obviate those difficulties, we will consider the circle ST as passing through the centre of the rim of a fly-wheel connected by arms with the small circle AB, representing a nave working on an axle at *c*. If the rim be supposed to weigh 150 lb. it might easily be revolved at the rate of two entire revolutions in a second by a handle at A, which is four inches from the centre, or so considered for illustration. When the winch A is moved about the axis, the force may be considered as acting by repeated slight impulses, as if it were applied at right angles to the radius of the circle, at each instant of time along the side of a polygon with an infinite number of sides, drawn within the circle. If the sides of the polygon be one hundred in number, they would be one fourth of an inch long, and then one and a half inches in the larger circle ST, will be the length of each side of a polygon along which the centre particles of the rim may be supposed to move. As the proportion of the circle ST is to AB as six is to unit, a moving power acting on the latter at the winch A, with a given force, through *g*, *h*, one fourth of an inch, will move the rim through *i*, *k*, equal to six times that space, with one sixth of the force applied; but as *the moment of rotation is equal to force multiplied by leverage*, the whole amount of force upon the rim through that space must be exactly equal to the power applied through the fourth of an inch upon A. And so of each side of the two polygons respectively. But they are considered infinitely small and ultimately become parts of the two circles; the power therefore must be applied in a circle, and the particles of the rim must be propelled in circles with a force exactly equal to that power. Consequently, the moving power, applied to a fly-wheel or to any other revolving body, cannot be expended in pressing the particles of such bodies from the centres nor in the direction of tangents to the circles in which they revolve. And this is evident from the fact, that such moving bodies cannot give out nor impart, in any manner whatever, more force than is applied to revolve them. And *that force is not only equal* to the power applied, but it is always returned in the circle in which the body moves, *and in a direction contrary to that in which it was received.* "If a wheel spinning on its axis with a certain velocity be stopped by a hand *seizing one of the spokes*, the effort which accomplishes this is exactly the same, as, had the wheel been previously at rest, would have put it in motion in the opposite direction with the same velocity."* The force applied to the winch, in the case above, was wholly expended in giving velocity to the rim, with the slight exceptions mentioned. Consequently, whatever other forces may have operated on the rim whilst revolving must have originated in some other way. And yet those extraneous forces would amount to 1480 lb., as shown by the above formula, the rim weighing 150 lb. and being revolved at the rate of two entire revolutions in a second. No part of this force could be communicated to the arm of a man who would stop such a wheel by seizing one of the spokes, because *each particle* of the rim is acted upon by the central forces, which are always opposite and equal, in the direction of the radius of the circle *at that point;* and it has just been shown that the moment of rotation of each particle is equal to the moment of rotation of the power that impels it, but "as the direction of the central forces is in that of the radius, their moment of rotation is equal to nothing."† Consequently the centrifugal force cannot act upon the hand that stops the wheel. If, indeed, the centrifugal force were increased to sixteen times the above amount, the result would be the same. By giving the wheel eight revolutions in a second we would have the central force $= 1480 \times 16 = 23{,}680$ lb. and the force in the circle would be $= \dfrac{12{\cdot}57 \times 8 \times 150}{16} = 925$ lb. Here the centrifugal force is twenty times greater than the force in the circle, and yet as the central force would act in the direction of the radii, its moment of rotation would be $= 0$. Or, what is more strictly the fact, the central force acts by pressure, and a resultant from that pressure and the force in the circle is the consequence, but so long as resistance from cohesion continues, neither motion nor pressure can be imparted to another body by the central force. These are the obvious reasons why no greater force could be communicated by the rim than the 925 lb., which it only possesses as a mass of matter moving in a circle.

The following experiment may be considered as a practical illustration of the theoretical views given above. A whirling table may be made of any convenient size, we will say, for the present occasion, rather more than four feet in diameter, to revolve horizontally on friction rollers placed near the centre; the axle being a hollow cylinder, through which four cords pass to the floor to be connected with a tin tube for containing shot or some other weight. The cords are brought over the pulleys *p, p, p, p*, fig. 3, at the centre, and secured to the dishes *d, d, d, d*, weighing one pound each, and moving, with very

Fig. 3.



little friction, on little wheels adapted to the strips or rails *r, r, r, r*. By connecting this table with wheel-work, having bands or teeth acting on the hollow cylinder as a spindle, by means of a weight or power

* Kater and Lardner on Mechanics, p. 24.
† Renwick's Mathematics. Art. Composition of Forces.

suspended by a rope wound round an axle, and moving *very slowly*, a certain number of revolutions in a minute will be given to it by the power, in passing through a given space, and the four dishes will raise, by their centrifugal force, a weight in the tube below, proportionate to the velocity and their distance from the centre. If the *moving power be then doubled*, with a slight addition to overcome the additional friction and atmospheric resistance, it will be found, *that in moving through an equal space in the same time*, it will give twice the former velocity, and the dishes, at the same distance from the centre, will raise in the tube below, in an equal time, *quadruple the weight first raised*. Then by loading the dishes and increasing or diminishing the velocity, and varying the distances of the dishes from the centre, a variety of experiments may be made, and weights may be raised, with corresponding distances and velocities proportionate to those given above.

By observing the manner of performing the experiments with the magnetized bar, it will be seen that a centrifugal force is excited, INDEPENDENTLY OF THE PROJECTILE FORCE, equal to the supposed power of the magnet, and we have shown that the same effects would follow without the use of the magnet. And that the impelling or moving power performs no other part in producing the complex effects attendant upon rotation, than simply to move the particles of a mass of matter in circles about a fixed axis, may be clearly shown by the theory of curvilinear motion, which those experiments were designed to illustrate. But without attempting to prove this at present, by abstract mathematical reasoning, the nature of deflection and the extent of its operation in exciting the central forces, may be explained by a reference to the action of electro-magnetism as shown in Fig. 4.

The bar A, when attached by the magnet, being supposed to revolve in a circle of one foot in diameter, at the rate of eight revolutions in a second, or 25·14 feet, to determine the amount of deflection in any unit of time, say one fiftieth of a second, the whole space through which it moves in a second may be divided into fifty parts, which will give six inches for each unit of time. If this space be measured on the tangent from B to *x*, and on the circumference of the circle to *r*, the deflection for the one fiftieth of a second would be equal to the square of B*r*, divided by BD, or the diameter. For by dynamics, "if a body revolve uniformly in a circle, the space through which it would move by the action of the centripetal force alone in any unit of time, such as a second, will be equal to the square of the arch described in the same unit divided by the diameter or twice the radius."* And the deflection of the bar in the $\frac{1}{50}$ of a second $= \frac{Br^2}{2Bc} = \frac{6^2}{2r} = 3$ inches. That is, the deflection from the tangent B*g*, during the time that the bar would have passed over six inches in that line, is three inches; and the deflection corresponding with the space B*g*, which is equal to two feet, and through which the bar would have passed in the $\frac{1}{12}$ of a second, would be $= \frac{2^2}{2r} = 4$ feet, and so of any other space.

Now to show that the amount of this deflection or centrifugal force depends upon the curve in which the bar is moved in a given time, and not upon the moving power, or projectile force, we will cause the same bar, moving with an equal uniform velocity, to be attracted in a similar manner by the magnet *m*, attached to an arm revolving in a circle of eight feet in diameter, and let EF be an arch of that circle, touching the straight line A*g* at B. As the velocity of the bar and the circumference of the circle are equal, the bar, after being attracted by the magnet at B, would move on with the same uniform velocity and perform one entire revolution in a second, friction and the resistance of the atmosphere being considered equal to nothing. And its deflection from the straight line, or its centripetal force for $\frac{1}{50}$ of a second, would be equal to the square of the arch B*z*, which is six inches, divided by the diameter of the circle, that is $= \frac{6^2}{8} = \cdot375 = \frac{3}{8}$ of an inch, or only one eighth of the deflection caused by the smaller wheel; and in the same ratio for any other spaces through which the bar would have passed whilst moving through equal spaces in the circle. And hence it is that the central forces are inversely as the diameters of the circles in which a body is made to move with a given velocity. The increment of deflection for an entire second being $= \frac{25\cdot14^2}{1} = 632$ feet per second in the smaller wheel, and in the larger one $= \frac{25\cdot14^2}{8} = 79$ feet per second only; and yet the bar has precisely the same velocity, and consequently the same force in the latter that it had in the former. Therefore, aside from friction, it would, if welded to *m*, require no more force to revolve it in the former than in the latter case.

For the same reasons, with a given velocity for the particles of the rims, the smaller a fly-wheel is, the greater will be the amount of centrifugal force, other things being equal. This will appear obvious upon inspecting the figure; for it will be seen that a particle of iron at *r* in the rim of a small wheel would be deflected from the straight line eight times as many inches in a given unit of time as a particle would be at the point *z* of the large wheel. The measure of the deflection from that line must therefore be the measure of the centrifugal force for any instant of time; and consequently the aggregate amount will be proportionate to the curve in which the body moves. This deflection takes place when a body is moved in a curved line, and the tendency to resist it and move in a straight line is excited in such a mass of matter in obedience to the important law of inertia, with as much certainty as electricity would result from the action of sulphuric acid upon two contiguous plates of zinc and copper. *Centrifugal force may therefore with propriety be considered a physical agent, which is called into action, by an inscrutable law of nature, whenever matter is made to move in a curve;*—which ought to be no more a subject of surprise, than that magnetic force should be excited in a bar of iron by certain chemical operations, the precise nature of which is as little understood as that of inertia.

The centrifugal principle has been employed as a projectile force from the earliest ages. It would be interesting to notice the extent to which it was used in ancient wars; and particularly to point out, as might be done even with the feeble lights afforded us, how much Archimedes was indebted to the central forces for the destructive effects of his engines, which I believe to have been no fabled nor imaginary productions of genius.

As I shall here come in conflict with some generally received opinions, I will give a short extract from Professor Renwick's Elements of Mechanics. Not that he differs from other writers on this subject, but I find that the extract will be useful in explaining what is to follow. "The simplest case of central force is where a body connected with a fixed point by an inflexible straight line is impelled by a projectile force at right angles to that line. The latter force would have impressed upon the body a motion with a uniform velocity. The body, then, in consequence of its connexion with a fixed point, describes a circle of which that point is the centre. If the connexion were to cease at any point in the curve, the deflecting force would cease to act, and the body would go in a straight line whose direction would be a tangent to the curve. The force acting at any point in the curve must therefore be decomposed into two, one of which is in the direction of the curve, the other in that of the radius."†

If a ball at A, Fig. 4, weighing one pound, and attached to an inflexible rod AC, two feet long, be impelled by a projectile force or moving power at the rate of two entire revolutions in a second, or $25\frac{14}{100}$ feet per second, it will have a centrifugal velocity equal to 157·76 feet per second.‡ Those two velocities, then, equivalent to the forces 1·58 lb. and 9·87 lb. respectively, constitute the aggregate amount of force acting on the body at any point of the curve or circle; the former acting in the direction of the curve, and the latter in that of the radius—one caused by the motion of the particles of matter, the other excited by a cause producing pressure, resisted by cohesion. Now, according to the fundamental principles of mechanics, "the same cause acting upon a body will either produce motion or pressure, according as the body is free or restrained." And, "if two forces act upon the same point of a body in different directions, a single force may be assigned which, acting on that point, will produce the same results as the united effects of the other two." Here we have two forces acting on each particle of the revolving body, but they are resisted by cohesion, therefore when cohesion ceases to act, the effect of the two forces must be, according to the theorem of the composition of forces, to impel it in the direction of their resultant, and with an amount of force equal to their mechanical equivalent; and experiment shows the correctness of the theory. If an ounce ball of lead, with a small hole drilled through it, be firmly secured by a catgut string close to the perimeter of a fly-wheel, or any other wheel that can be rapidly revolved, it may be discharged from the vertical point of the circumference, whilst the wheel is revolving, by interposing a sharp knife well fixed in a slide. When the velocity necessary to project the ball horizontally at a given short distance has been ascertained, then by increasing the velocity and taking care to discharge the ball from the same point of the circle, and at an equal distance from the centre of the wheel, its elevation will be found to increase with the increased

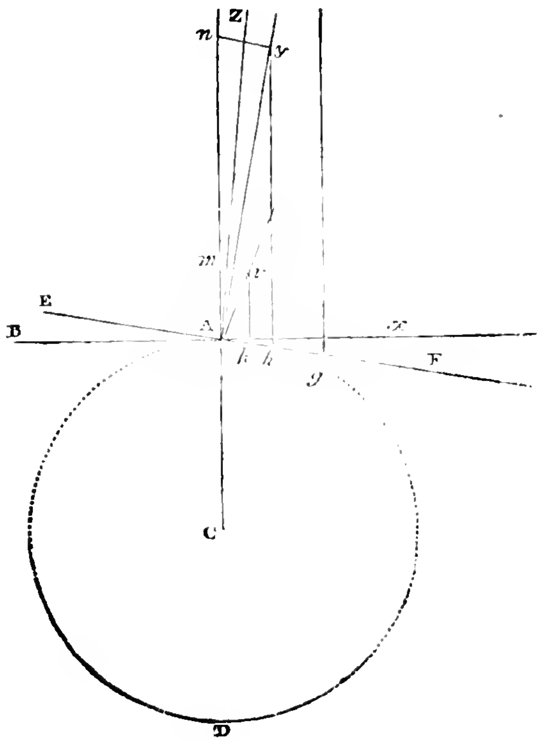
Fig. 4.



projectile force. And the experiment may be varied by having a number of balls prepared of the same weight, and varying the velocities and the distances from the centre. The effects of gravity, however, and the difficulty of representing by a straight line what may be considered the direction of the circle, have prevented me from determining *geometrically the direction* of the projectile, although in practice it may easily be ascertained.

If the ball be discharged from the point A with one revolution in a second, its velocity in the circle would be 12·57 feet per second, and its centrifugal velocity would be $= \frac{v^2}{2r} = \frac{12{\cdot}57^2}{4} = 39{\cdot}44$ feet per second, and the initial projectile velocity would be $= \sqrt{12{\cdot}57^2 + 39{\cdot}14^2}$ $= 41{\cdot}40$ feet per second, disregarding for the present atmospheric resistance. And if, in the way of illustration, AF be considered as the direction of the force in the circle AD, the sides A*k* and A*m*, of the parallelogram A*mrk*, being made proportionate to the two velocities 12·57 and 39·50 respectively, the diagonal A*r* of the parallelogram will represent in direction and proportional amount the velocity 41·15 or initial projectile velocity. If a billiard-ball, moving upon a table with a velocity equal to 12½ feet per second in the direction EF, were to receive at A an impulse in the direction of *cn*, which alone would cause it to move with a velocity equal to 39½ feet per second, no other direction and velocity could be assigned to it, than that designated by the diagonal A*r* of the parallelogram. The revolving ball is supposed to move in the direction A*k* with the velocity of 12·57 feet per second, represented by that side of the parallelogram, and at the same time to be acted upon by a force which would cause it to move with a velocity equal to 39½ feet per second, in the direction of the side A*m*, which indicates that velocity, consequently *no other direction nor amount can be assigned to it, when projected, than the diagonal* A*r of the parallelogram* A*mrk*. If the velocity of the ball be doubled, the centrifugal velocity increasing as the square of the increased velocity in the circle, it would be $= 39{\cdot}14 \times 4 = 157{\cdot}76$ feet per second, and the initial projectile velocity would be $= \sqrt{25{\cdot}14^2 + 158^2}$ $= 160$ feet per second; and the two first would be represented by the sides A*h* and A*n*, respectively, of the parallelogram A*nyh*, and the diagonal A*y* would indicate the direction and relative proportion of the initial projectile velocity. With four revolutions in a second, the initial projectile velocity would be 635 feet per second, in the direction of the line A*z*. At least such would be the directions for those three velocities *at the instant the ball leaves the point from which it may be discharged.* But with such low velocities a pound ball would not indicate those directions by its path, for the reasons given above. *With very high increasing velocities*, however, the experimenter will find that a small leaden ball will move in directions approaching that of the radius, as shown in the diagram. In repeated experiments made with a machine revolving vertically, and having a tube placed in the direction of a tangent to the circle in which leaden balls were revolved, it was found that with very high velocities they were forced through the tube with difficulty, and a portion of each was removed by the friction, and the upper part of the tube, on the inside, was worn smooth. But with much lower velocities the balls passed through the tube without any apparent friction.

In performing the first experiment, the bar, (A, Fig. 1,) moving with uniform velocity in every part of the circle BD, has the same centrifugal force at *r* that it would have after revolving for a minute or more; for the amount of that force depends upon the curvature and the circular velocity, and consequently was excited to the amount of thirty-nine pounds instantaneoosly, and if it had been discharged at three inches from B it would have been projected with that force. If this were not the case with bodies moving in space, supposed to be thus deflected, they would fall to the centre of attraction. Now as this is the fact, the *tangent* B*x* in the diagram only serves, as every mathematician knows, to show geometrically *the amount of deflection in a unit of time*, measured at right angles to that line, the space *xr* representing that through which the centripetal force alone, acting uniformly, would cause the body to fall in the fiftieth part of a second; the tangent, therefore, represents THE LINE FROM WHICH *the body would be deflected in an instant of time, and* NOT *that in the direction of which it would move with all its projectile force.*

Again, if the segment of a fly-wheel disintegrated by centrifugal force would be projected "in a straight line, whose direction is that of the tangent," the pressure which produces the fracture must act upon each particle of iron in the direction of a tangent to the circle in which the particle is revolved, for the direction of a moving body is always that in which a single force, or the resultant of two or more forces, acts to cause the motion. And it is self-evident that no amount of force, applied in that direction upon the particles in the revolving rim, could overcome the attraction of cohesion. And it is equally evident that such cannot be the direction in which the pressure acts, for whilst it is stated that the tangent is the direction in which the dissevered fragment is projected, we are informed that the force which causes the fracture acts at right angles to the tangent.

By the theory given above, however, which is founded upon observation and experiment, all the circumstances that attend this phenomenon are easily explained. And when we consider the immense increase of centrifugal force as the velocity of the rim is increased, *and the direction in which the resultant of the two forces acts*, we ought not to be surprised to find that such masses of iron can be broken and projected with so much destructive effect by this powerful agent. The operation of the sling may also, in this way, be explained in a few words. For a man, with a thong three and a half feet long, has only to give to a stone at the final effort a velocity, in a very small segment of a circle, equal to 132 feet per second, which would be at the rate of 360 revolutions in a minute, and he will project it with a force equal to that given to a ball of the same weight by an ordinary charge of gunpowder, after deducting one-third of its initial velocity for atmospheric resistance. But to "accumulate" an equal force in the circle by the strength of his arm, he would have to revolve the stone at the rate of 6850 revolutions in a minute, which is impossible.

Without intending to enter into any particulars as to the probable results of a practical application of this principle, I will close with a few remarks designed to show the amount of force excited by the rotation of heavy bodies about fixed axes, and the extent to which we may reasonably conclude it might be employed, if it could be controlled, by giving the relative proportions of the power necessary to revolve a body and the central force excited, considered abstractedly, apart from friction and atmospheric resistance. "The arc which the revolving body describes in a given time is a mean proportional between the radius of the circle and double the space which its centripetal force alone, acting uniformly, would cause it to fall through in the same time."* Consequently the diameter is to the circumference as the circumference is to the space which the centripetal force of the body would make it fall through in the time of one revolution. That space, therefore, is to the circumference as 3·141 is to unit, [3·141 being the circumference of a circle whose diameter is unit,] and the central velocity or force for an entire revolution in a second is equal

* Cavallo's Nat. Philos. p. 66.

to the circumference multiplied by 3·141. Hence *the ratio of the central force to the force in the direction of the circle, or the moving power, is as the product of the number of revolutions in a second by 3·141 is to unit.* That is, if there be two entire revolutions in a second, whatever be the weight of the body or its distance from the centre, the ratio of the centrifugal force to the moving power would be as 3·141 × 2 is to unit, or as six to one, nearly; and with eight revolutions in a second the ratio is as 3·141 × 8 to unit, or as twenty-five to one. And since "the velocity of rotation is almost unlimited,"* if a fly-wheel, similar to the one described above, were revolved at the rate of twelve hundred revolutions in a minute, the excited or centrifugal force in the rim would be equal to sixty-two and a half times the amount of power employed to give the requisite velocity, some deduction being made for friction and atmospheric resistance.

ON THE POWER OF FLUIDS IN MOTION.

In Silliman's American Journal for January last appears the following abstract of a paper read at the American Philosophical Society, "On a new Principle in regard to the power of Fluids in Motion to produce Rupture of the Vessels which contain them, and on the Distinction between Accumulative and Instantaneous Pressures: by Charles Bonnycastle, Professor of Mathematics in the University of Virginia."

Mr. Bonnycastle's investigation was suggested by a paper read by Dr. Hare, and printed in the Transactions of the Society, entitled "On the Collapse of a Reservoir, whilst apparently subject within to great Pressure from a Head of Water." Dr. Hare pointed out the circumstances attendant upon this curious occurrence, and showed how the vessel might have been momentarily relieved from the pressure of the water within, so as to make that of the surrounding air efficient in producing the collapse. The principal object of Mr. Bonnycastle's paper is to investigate the precise nature and degree of the forces brought into action in this and similar cases.

The results at which Mr. Bonnycastle arrived, are stated by him as follows:—

1. It is convenient to distinguish between accumulative and instantaneous loads, or between those which are gradually increased until the deflection due to the ultimate load is obtained, and those which commence in full efficacy from the initial position of the support.

2. Within the limits of perfect elasticity, instantaneous pressure produces twice the effect of that which is accumulative, whether the result be to produce deflection or fracture.

3. In regard to supports perfectly elastic in one direction, and perfectly flexible in the other, instantaneous action, at right angles to the axis of elasticity, produces a deflection which is to that of accumulative action as $\sqrt{4}$ to 1, whilst the tendencies to fracture are as 4 to 1. But should any case occur when the law of elasticity follows an extremely high power of the deflection, then the singular result will follow, that the deflections are the same, whether the force be exerted from the initial state or the state of load, but that the tendency to fracture will be immensely greater in the former case than in the latter.

4. In producing the fracture of natural substances, which all depart from the law of perfect elasticity as we approach the limit of fracture, the ratio of the effect of instantaneous and accumulative action will vary with the nature of the substance, never being less, for elastic bodies, than 2 to 1, nor for flexible than 4 to 1, and more usually approaching 3 or 4 to 1 for the former case, and 5 or 6 to 1 for the latter.

5. Let a vase or conduit be acted upon by a load which is alone sufficient to break it, and let this load be partly balanced by a small exterior force; should the great interior force suddenly cease, the small exterior action may crush the vase or conduit inward; its energy in such case being the sum of the interior and exterior forces.

6. Should the interior force be a vibration of the kind already explained, and should the exterior action be extremely feeble, and act on a very great mass, this extremely feeble action may crush the vase inward, with a power that shall exceed in any degree the enormous action of the interior or explosive vibration. The comparison of the interior and exterior actions is best effected in this case, by finding the modulus of elasticity of a material spring that shall coincide most nearly in effect with the interior tremor. For putting ϵ and ϵ' respectively for the modulus of the spring and of the support, and σ and σ' for the deflections resulting from the tremor acting alone, and the reaction as it does act, we have $\frac{\sigma'}{\sigma} = \sqrt{\frac{\epsilon}{\epsilon'}}$, or, in other words, the deflection produced by the reaction, is to the deflection that would be produced by the interior tremor alone, in the inverse proportion of the square roots of the moduli of tremor and support.

7. Combining what is here said with the known laws of fluids moving in pipes, and whereby they necessarily produce hydraulic shocks, it follows, that any vessel connected with such a train of pipes, and plunged at some little depth in a considerable mass of water, or other heavy fluid, will occasionally be subject to a crushing and exterior force vastly greater than the interior strain due to the constant head of fluid.

In illustration of the principles thus developed, Mr. Bonnycastle details some experiments, and mentions a phenomenon which occurred under his own notice, and is analogous to the one described by Dr. Hare. In making experiments on the propagation of sound through water, he had occasion to cause an explosion of gunpowder within a hollow metallic cylinder, open at the lower end, and immersed under the liquid; and, although the strength of the cylinder was abundantly sufficient to bear the statical pressure of the surrounding water, he found it crushed inward after the explosion.

* Fisher's Nat. Philos.

ROMAN ARCHITECTURE.

[We have heretofore had occasion to speak in praise of several articles on architecture which have appeared in the "Penny Encyclopædia," and have given several extracts; we have now much pleasure in making some additional extracts from a very able article on "Roman Architecture," which appeared in one of the recent numbers.]

With regard merely to the orders, Roman architecture presents chiefly a corruption of the Doric and Ionic, for it may claim the Corinthian as almost entirely its own, the Roman examples of that order being not only numerous and varied, but at the same time exceedingly different in character from the almost solitary specimen of one with foliaged capitals which occurs in a Grecian building. But even as regards the application of the orders, there is a wide difference between the two styles; in the Roman they are frequently employed as mere decoration, the columns being *engaged* or attached to the walls, or in some cases (as that of triumphal arches) though the columns are insulated and advanced from the structure, they are in a manner detached from it, inasmuch as they do not support its general entablature, but merely projecting portions of it. Nor are these the only differences, for besides the frequent employment of pilasters as substitutes for columns—that is, as constituting the order without columns—the practice of *supercolumniation*, or raising one order upon another, was by no means uncommon; a practice that was indeed a matter of necessity in such enormous edifices as the Colosseum, if columns were to be employed at all. From all this it will be evident that, as regards the orders alone, there is a very marked difference between Roman and Grecian architecture; yet such difference is by no means the whole, the two styles being almost opposites in nearly every respect. If there were no other distinction between them, that arising from the arch, and diverse applications of its principles to vaults and domes, would be a very material one; but we also meet with a variety and complexity in Roman buildings which does not occur in those of Greece. The only instance that we are acquainted with in Grecian architecture, of anything like grouping or combination of building, is that of the Erechtheion, or triple temple on the Acropolis of Athens. With this exception, Greek temples were merely simple parallelograms, differing from each other as to plan only in the number and disposition of the columns around the cella; consequently, however beautiful when considered separately, a very great monotony prevailed in that class of buildings, at least, in which the forms were so limited and fixed as to preclude any fresh combinations, or anything approaching to what is understood by composition.

By the adoption of the circular form in their plans, whether for the whole or parts of a building, the Romans introduced an important element of variety into architectural design; especially when we consider that to such shape in the ground plan is to be ascribed the origin of the *tholus*, or concave dome, which harmonizes so beautifully with all the rest, and renders the rotunda-shape at once the most picturesque and the most complete for internal effect,—that in which both unity and variety are thoroughly combined. The Pantheon alone would suffice to convince us that the Romans were not mere copyists, and that if as such they deteriorated the Greek orders, they also added much to the art, and greatly extended its powers by new appliances. As regards its exterior, the Pantheon presents what is certainly a strikingly picturesque (and what we consider to be also a consistent and appropriate, because a well-motived) combination, namely, of a rectangular mass projecting from a larger circular one. In that example the body of the edifice, or rotunda itself, has no columns externally; but circular peristylar temples, or rotundas, whose cella was enclosed by an external colonnade, were not uncommon. Of this kind is the temple of the Sibyl, or, as it is otherwise called, that of Vesta, at Tivoli, an edifice of singular beauty, and highly interesting as a very peculiar and unique example of the Corinthian order, the first application of which in any modern building was made by Soane, at the Bank of England. Edifices of this kind were covered with hemispherical domes, or with smaller sections of a sphere, which consequently did not show themselves much externally, as they were raised only over the *cella*, and therefore the lower part was concealed by the colonnade projecting around it. The dome of the Pantheon is hemispherical within, but is of very low proportions and flattened form without, for its spring commences at about the level of the first or lower cornice of the exterior cylinder, and is further reduced by the base of the outer portion of the dome being expanded and formed into separate cylindrical courses or gradini. If the dome had sprung immediately from the upper cornice, so as to present a perfect hemisphere on the outside, the rotunda itself would have looked merely as a *tambour* to it, and the effect would have been as preposterous as if the cupola of St. Paul's and the colonnaded rotunda on which it is raised were placed immediately on the ground, instead of being elevated upon a larger pile of building.

Polygonal forms of plan were sometimes employed, of which there is an instance in what is called the temple of Minerva Medica at Rome, which is circular on the exterior, but internally decagonal, with nine of its sides occupied by as many recesses, and the other by the doorway—a remarkable peculiarity, it being very unusual to enclose a polygon within a cylindrical structure, although not the contrary, nor to erect a cylinder upon a square or polygonal basement. Octagon plans were by no means uncommon: such form was frequently made use of for the saloons of public baths; and there is an instance of an octagonal temple, supposed to have been dedicated to Jupiter, in one of the courts of Diocletian's palace at Spalatro. Of hexagonal structures we are acquainted with no example, but a court with six sides occurs in the remains of the temple of Baalbec, not however a regular hexagon, but of elongated figure, two of the sides being 110, and the remaining four 88 feet each. In the later periods of Roman architecture, circular and polygonal structures became more frequent, and those of the first-mentioned kind deviated considerably from the original simple rotundas and circular temples. An inner peristyle of columns was introduced so as to make a spacious circular or ring-shaped ambulatory around the centre, which was much loftier than the colonnade being covered by a dome raised upon a cylindrical wall over the columns. What is now called San Stefano Rotunda, at Rome, supposed by some to have been originally a temple dedicated first to Faunus, and afterwards to the emperor Claudius, and by others to have been a public market, is a structure planned according to the arrangement just mentioned, with a circular Ionic colonnade of twenty columns and two piers. The Church of Santa Costanza, traditionally reported to have been a temple of Bacchus, but now generally supposed to have been erected by Constantine as a baptistery, and afterwards converted by him into a funeral chapel to his daughter Constantia, is a remarkable example, owing to the columns being not only coupled, but unusually disposed, and to there being arches springing from their entablature, that is, there are twenty-four columns (with composite capitals) placed in pairs, on the radii of the plan, or one behind the other, forming twelve inter-columns and as many arches: and as far as the mere arrangement goes, this interior is strikingly picturesque; but it would be an improvement, if the dome were in such case to spring immediately from the imposts of the arches, and the latter to groin into it; or at least were it to spring from the vertex of the arches.

The circular form was a favourite one with the Romans for their sepulchral structures of a more pretending class than ordinary. It will be sufficient here merely to mention those in honour of Augustus and Hadrian. The tomb of Cæcilia Metella is a low cylinder, the height being only 62 feet, while the diameter is 90; and it may be considered as nearly solid, the chamber or cella being no more than 19 feet in diameter. This cylindrical mass is raised upon a square substructure; which combination of the two forms is productive of agreeable contrast; and it was accordingly frequently resorted to. The tomb of Plautius Sylvanus near Tivoli consists also of a short cylindrical superstructure on a square basement, but is otherwise of peculiar design, one side of that stereobate being carried up so as to form a sort of low screen or frontispiece, decorated with six half-columns, and five upright tablets with inscriptions, between them. The tomb of Munatius Plancus, at Gaeta, is a simple circular structure, of low proportions, the height not exceeding the diameter, and therefore hardly to be called a tower, notwithstanding that it is now popularly called Roland's or Orlando's Tower. Of quite different character and design from any of the preceding ones, is the ancient Roman sepulchral monument at St. Remi, which consists of three stages; the first a square stereobate raised on gradini, and entirely covered on each side with sculptures in relief: the next is also square, with an attached fluted Corinthian angle, and an open arch on each side; and the uppermost is a Corinthian rotunda, forming an open or monopteral temple (i. e., without any cella), the centre of which is occupied by two statutes.

These notices may serve to convey some idea of the variety aimed at by the Romans in the distribution of the plans and general masses of their edifices, independently of decoration. Their thermæ, or public baths, a class of structures remarkable for their vast extent and magnificence, are most interesting studies of combinations of plan, as they were not merely baths, but places of public resort and amusement, and consisted of an assemblage of courts, porticos, libraries, and spacious saloons and galleries, most of which presented some peculiarity of form and distribution.

The Romans seem to have affected the practice of grouping buildings together as features in one general symmetrical plan. Their temples and basilicas were frequently placed, as the principal architectural objects, at the extremity of a forum, or other regular area enclosed with colonnades. The temple of Nerva stood at one end of, and partly projected into an enclosure (measuring about 300 by 160 feet), the entrance end of which had five open arches, and the sides were formed by screen walls, decorated with Corinthian pilasters, and columns immediately before them, over which the entablature formed breaks. Of Trajan's forum, which was surrounded not only by colonnades, but various stately edifices, nothing now remains except the celebrated triumphal column that occupied its centre, and which, so placed as a principal object, must have heightened the splendour of the whole. Like that of Nerva, the temple of Antoninus and Faustina was placed at one end of a court of moderate dimensions, whose sides were adorned with coupled columns placed immediately against the walls; and only the portico part of the temple (a Corinthian hexastyle, triprostyle) advanced into the enclosed area in front. The forum of Caracalla was nearly a square, entirely surrounded by arcades, presenting thirteen arches on each of the longer and eleven on each of the shorter sides. In the centre was a Corinthian temple very similar in plan to the Pantheon, with an hexastyle, triprostyle portico in front, and remarkable for having inner columns behind the second from each angle, so that there was a double range of them at each end, and the central space within the portico was a perfect square equal to three intercolumns.

As our object is rather to direct attention to the modes of composition affected by the Romans and the elements of their style, than to describe their chief architectural monuments, either historically or according to their respective classes and destination, we proceed now to consider some of the individual peculiarities and features belonging to their buildings.

In the application of sculpture, particularly of statues, they were prodigal; but they employed the latter chiefly as architectural accessories, frequently placing them over columns, or on the summits of their edifices as acroteria to pediments, by way of giving variety to the outline of their buildings, and also of indicating at first sight their particular appropriation—a practice almost unknown to the Greeks, there being only one instance of it. In Italian buildings, on the contrary, the practice has been frequently carried to a preposterous extent, rows of statues being placed on the pedestals of balustrades, so as almost to look like pinnacles, and to produce rather a stiff and formal effect than one of richness; whereas when they are introduced on the angles and apex of a pediment, or when there is merely one in the latter situation, such monotony does not take place, and additional importance and loftiness may be given to that portion of the edifice by such decoration. The abundant use of statues led to the adoption of the niche—a feature unknown in Greek architecture—as a convenient mode of inserting them within the surface of walls, and thereby decorating them; at the same time space was gained in interiors, where, if otherwise placed, they would have taken up room. Niches frequently occur in Roman temples and baths; and, as we have seen, from the account given of the temple of Venus and Roma, were occasionally decorated with a frontispiece of small columns, with their entablatures and pediments, but were generally left plain, and were for the most part semicircular in plan, in which case they usually terminated in an arch and semidome, after the manner of a tribune or large recess, of which the niche was in fact a miniature copy. Niches, however, were very frequently rectangular in plan, as were also exhedræ, or recesses, in which case the latter formed arches vaulted hemicylindrically.

These various applications of curvilinear forms, both in plan and elevation, undoubtedly furnished Roman architecture with resources unknown to that of Greece. Nor can it be denied that the arch itself is a very beautiful feature, although it was employed by the Romans to such excess as rather to occasion monotony than to contribute to variety of design; for if the general character of Greek temples was invariably uniform, presenting in the exterior merely lines of columns, the amphitheatres and similar works of the Romans consisted only of continuous tiers of arches, which constituted their more strongly marked features, the columns placed against their tiers being merely ornamental accessories, and comparatively of little effect, and even that not of the very best kind. In either case—the Roman or the Greek—a single compartment of an edifice, whether arcaded or colonnaded, serves as a pattern for the whole; and although uniformity and continuity conduce to grandeur, yet if precisely the same kind of uniformity recurs in every building of the same class, it becomes wearisome.

We now come to consider a practice eventually adopted, by means of which the arch and column became amalgamated as integral parts of the same ordinance, viz. that of supporting arches upon columns, making them spring either directly from their capitals or from an entablature-shaped block over them. We are aware that this practice is almost uniformly condemned as barbarous and absurd; yet in our opinion somewhat too hastily, and with more of prejudice than of fair examination. That it was introduced during the decline of the art, and that it was an innovation subversive of former principles, is not to be denied. Yet if it must be reprobated, it ought to be so for its own demerits, not as an innovation; for all invention is such. It appears a very poor argument against it, to say that columns were originally designed to support horizontal architraves; we do not see how that circumstance, of necessity, renders every other application inadmissible. At that rate we must censure as vicious a great deal of both Roman and modern architecture, where attached columns are employed merely as ornaments, yet, as frequently as not, in such manner as to produce a character of littleness and poverty, they being so small in proportion to the rest as to appear insignificant, and at such intervals from each other that all the beauty and harmony of a columnar ordinance is lost. Where columns are employed to support, it certainly cannot be alleged that they are idle unmeaning expletives: nor that they are mutilated by being apparently partly embedded in the wall behind them. "A pier," it has been remarked by an intelligent waiter, "is but a differently shaped and more massive column:" which being granted, what impropriety can there be in employing the latter as a substitute for the other, provided it be done with judgment and discretion, and where, upon the whole, it will prove an advantageous mode of treatment? It certainly is a barbarous mode to turn small arches upon columns, which are not more than between two and three diameters apart, of which we have examples in the basilica of S. Paolo, and Santa Agnese fuor delle Mura, at Rome. The intercolumns are such that they might easily have been closed horizontally: indeed the openings between the columns have scarcely the appearance of being arches; but the whole looks as if the wall resting upon the columns was scooped out into diminutive arches over the intercolumns. In those instances, too, the arches themselves are quite plain, without archivolt or mouldings of any kind, and consequently all keeping is destroyed: the architectural embellishment terminates with the capitals of the columns, and so far the effect is similar to what would be produced by placing a plain horizontal mass upon a range of columns, instead of a moulded entablature. Although one of an opposite kind, it is equally a fault to make the arches spring not immediately from the capitals of the columns, but from square fragments of entablature over them (as, for example, in the interior of St. Martin's, London) not only because such fragments are unmeaning in themselves, and suggest the idea of the columns having been found too short for their intended purpose, but because they remind us quite unnecessarily of the original application of the column to the horizontal entablature. If entablature be admissible at all, it is when the columns are coupled, as in the church of Costanza already noticed: for then some kind of architrave at least becomes requisite, in order to connect the two capitals, as it were, together. One very great advantage attending the combination of the arch with the column as its support, is, that it allows the openings to be considerably wider than they otherwise could be, because such intervals as would produce a poor and straggling effect in a colonnade, become well proportioned and agreeable when spanned by arches. Such columnar arcades have frequently been employed by the Italians with happy effect in *cortili* and places of that kind, where piers of the usual kind would obstruct the view too much, and where intercolumns of the same proportions, between pillars supporting a horizontal entablature, would have a poor and disagreeable effect, particularly if, as is generally the case, other stories of the building rested upon the porticoes below. In fact, ordinances composed of arches and pillars constitute the best specimens of Italian columniated architecture. That in the cortile of the Palazzo Piccolomini at Siena, the work of Francesco di Giorgio, is singularly beautiful in its distribution, remarkable for the richness of its details, and also for the variety which it presents in perspective, as may be judged from the view of it given in Grandjean and Famin's "Architecture Toscane." We have already mentioned the interior of St. Martin's as containing an example of arches upon columns, and that of St. Bride's, London, furnishes another, but neither is a favourable one. A more satisfactory example may be found within the loggia of the Strand portion of Somerset House, where, though the arches spring from entablatures over the columns, yet as the latter are placed in pairs, those horizontal parts are more than mere upright blocks over the capitals. The quadrangle of the late Royal Exchange, London, had arches springing immediately from the capitals of the columns, but their breadth was excessive in proportion to the height of the latter, and their elliptical form was a great defect, and certainly did not at all contribute to beauty. All that we contend for is the principle on which the practice is founded; for as to the merits of the buildings in which it is adopted, that must, like every thing else in architecture, depend upon the taste shown in the particular application of it, which may be exceedingly good or altogether the reverse. Hungerford Market affords a good example of an ordinance composed of columns and arches, and also an idea of the general character of a basilica, though of course somewhat modified, and without any sort of architectural luxury.

ARCHITECTURE OF LIVERPOOL.

NORTH AND SOUTH WALES BANK.

In an article in thy Journal headed the Architecture of Liverpool, signed H., occurs the following sentence. "This is an example of the effects of modern competition, where the successful architect, having had his design adopted in consequence, it is said, of his private interest in the committee of management, has not only the advantage, as was understood at the time of examining those of his competitors, during the six weeks which elapsed between the decision of the committee and the return of the designs to their respective authors, but is permitted to expend about twice the amount to which they were in the first instance limited;" which under the mean mark of, "it is said," hides four distinct assertions meant to reflect discredit on the committee of management and on myself,—all four are thoroughly untrue. In the first place 1, the architect, had my design chosen unanimously by the committee, without the interference of any private interest. Secondly, I did not either at the time of the designs being before the committee, or any other time see, or have opportunity to see any one of them, (excepting only the one considered second best, sent by Mr. Leigh Hall, of Manchester, and to see which, I went to his office by his own invitation some months afterwards.) On the contrary, the manager of the bank carefully kept them unseen after the decision, until at various times they were sent for by their owners—considering it his duty to the unsuccessful architects; and certainly I should not have been mean enough so to examine them, or under the shuffling cloak of the words "understood at the time," to assert and publish anonymously that any other person did so, unless I had known it of my own knowledge. Thirdly, The time the plans were in the directors hands was four, and not six weeks, and during all that time I was engaged in a tour in the west of Scotland and the north of England. And fourthly, no amount whatever was named to limit the architect, and the sum expended is not greater than was anticipated, and shown by the architect, except such part of it as is due to the fact of the foundations having to be taken down 27 feet below the surface, in consequence of the discovery of the site being partly that of the old castle ditch of Liverpool, and which part of the cost is well invested by the building in that depth, strong and valuable bonding vaults. I send a ground plan by which you will see that H. contradicts himself, by stating that the obtuseness of the angle is rendered "most painfully obvious," by my having placed the line of wall "at right angles to the long side, and therefore not parallel to its own line of front;" *it is* parallel to its own line of front, and therefore is 6¼ feet in 35 more obtuse than a right angle; surely the writer must have distorted vision who could not see the difference between an angle of 101 degrees and a right angle, even when it was rendered "most painfully obvious," the fact shows that the obtuseness of this angle was a "difficulty" so "overcome," as to baffle his discernment. That I have taken away by my pilasters two feet in width, and by the entrance five feet in length, is untrue; the bases are allowed by the town's authorities to project beyond the building line, and the space from the front of the pilaster to the inside of the stone work of wall is just two feet, so my judicious and veracious friend H. would leave nothing for the thickness of the wall; this blunder arises no doubt from the common practice of making pilasters merely accessory; in my building they *are the wall*, and are throughout the structure *the support*. The building has been admired not only by your judicious writer "Eder," but by many whose opinions are at least as well worth having as that of the sharp-sighted H.

I am, respectfully,
EDWARD CORBETT, *Architect*.

King Street, Manchester,
3rd Month 2, 1841.

RAILWAY ACCIDENTS.

SIR—As the greater number of fatal accidents which have recently occurred on railways may be fairly (at least in my opinion) traced to a want of sufficient look-out ahead, it has occurred to me, that great advantage would result from having a third person as a conductor on the engine, whose duty it should be exclusively to attend to the signals, keep a look-out ahead when the train is in motion, and apprise the engineer of any other train, workmen, materials, &c., being on the line from which danger may be apprehended, as also to apprise such train, workmen, &c. of the approach of that to which he is attached.

This person should not be associated with the engineer and stoker on the stage behind the fire-box, but should be elevated on a seat before the chimney, where he would at all times have a much better opportunity of keeping a look-out than the engineer has, whose view is often partially or entirely obstructed (as I have frequently observed) by the steam escaping from the valves, or by the smoke and steam from the chimney, besides the disadvantage the engineer always labours under in looking along the side of the boiler. The situation of the conductor would be particularly advantageous in the night for observing the signal lamp of a train in advance, which from its position may be easily overlooked by the engineer, who has the light of his own fire to distract his attention.

The situation of the conductor which, is herein advocated, I am aware would be attended with little advantage without an adjunct. I therefore propose that there should be two whistles on the boiler, over the fire-box, with levers and rods attached to them, leading to the seat of the conductor, so that by means of them he may easily communicate with the engineer, or give warning to the train or workmen, &c., on the line before him. One of these whistles should be used as a warning only, and the other to convey to the engineer a peremptory order to stop the engine in case of a sudden emergency. The engineer should still have, as at present, the means of working the cautionary whistle, independent of the conductor; and he might be furnished with an apparatus to arouse the attention of the latter in case of his being in doubt.

The responsibility and attention of the engineer would not necessarily be diminished by the adoption of this plan, on the contrary, while he should be required to keep as vigilant a look-out as at present, the superior situation of the conductor would be a great additional security to the lives and property of the public. The directors of railways incur, as was very properly expressed by them at their late meeting at Birmingham, a fearful responsibility, and it behoves them to take every precaution in their power for the protection of the lives and property intrusted to their care.

Should this suggestion prove to be the means of lessening the danger of the public, and the responsibility of those whose duty it is to protect them, the object I had in view by troubling you with this, will be fully answered. Begging the favour of your giving this a corner in your valuable Journal,

I remain, Sir, your most obedient servant,
A CIVIL ENGINEER.

Thornhill, near Wakefield,
March 11, 1841.

PUBLIC SAFETY AND CONVENIENCE.

SIR—It is to be hoped that the recent accident of two houses falling down in so public a thoroughfare as Fleet Street, which is constantly thronged during the day time, will at least have the good effect of exciting greater vigilance for the future. But, at present, it seems there is no adequate authority which can interfere imperatively and instantly in such cases; or, if there be any authority and responsibility, there must be most scandalous and criminal negligence somewhere or other.

Passing the other day through that not very refined but now classical locality of Pickwick celebrity, yeleped Goswell Street, I was struck by the frightful manner in which, owing to the accumulation of earth behind it, the churchyard wall bulges out above in such manner, that it looks as if about to give way. Would it not, therefore, be advisable to ascertain whether there is any real danger of its doing so, and whether it would not be prudent to strengthen it by buttresses at intervals?

That far greater attention is paid to the comfort and security of pedestrians in London than in any other capital or city, may be readily admitted; nevertheless there are improvements which might be adopted, were all that relates to the care of the public streets placed under the control of a general Board for the whole metropolis. Though it may be thought a very trifling matter in itself, it would be well were there some kind of authority to regulate the names of streets, and thereby prevent the inconvenience sometimes occasioned by the same name being borne by half a dozen or half a score different streets in various parts of the town. Surely it would not be a matter of great difficulty to find a distinct name for every street, even were the metropolis to grow to twice its present size. Therefore, although to attempt now to correct the present nomenclature, by naming afresh some of our numerous George Streets, King Streets, Castle Streets, might occasion as much confusion as it would obviate, there might be a regulation, ordering that in future, no new street should have a name already appropriated by some other.

Far more essential is it to the public that they should be enabled to cross such exceedingly wide carriage ways as those in Oxford Street, Regent Street, Charing Cross, Whitehall, Holborn opposite Furnival's Inn, &c., with less inconvenience and danger than they now incur. What objection there can possibly be to erecting a lamp-post here and there, with short posts around it, so as to form a secure spot midway of the crossing where foot-passengers might stand in security, it is difficult to conceive. It is true something of the sort has been done already, but not effectually; for the crossings are still left dangerously wide, as for instance, that opposite Northumberland House, where there ought to have been two lamp-posts and resting-places instead of a single one. Besides, why should there be none at all in Regent Street, &c., where they are quite as much wanted? or does it not matter whether people be run over by carriages in those particular places? Another thing that might be attended to, were it made any body's duty to do so, is the sweeping the crossings in dirty weather, for the swept pathway is generally so narrow, that if two persons meet, they must either jostle against each other, or one of them step into the mud. At the time of the thaw, some weeks ago, the streets were almost impassable for foot-passengers; which would not have been the case had the snow been entirely cleared away from the crossings, leaving there a passage of about 12 feet broad.

There ought to be some regulation for providing *urinals* at suitable distances, whereas, at present, there seems to be no regulation at all in regard to them, that being a public accommodation left entirely to chance; so that in many parts of the town it is difficult to meet with any place of the kind. Yet, if no where else, one might be fixed at the entrance to every carriage mews; and not only might they be better contrived than they usually now are, but it should be made the duty of the police to see that they are not scrawled over in the disgusting manner they frequently are.

Unfortunately it is worth nobody's while to make a stir about such matters, because they are not of the kind which the newspapers gabble about. No! any one might gain greater celebrity any day by merely standing on his head at Charing Cross.

I remain &c. &c.,
A PEDESTRIAN

Metallic Relief Engraving.—As you are ever anxious to give the first tidings of new inventions, I doubt not the two following embryo methods of engraving will be as interesting to yourself as to your readers:—Take a tablet of plaster of Paris, and, having heated it, apply wax for absorption to all the faces save that on which you intend yo r drawing to be, and to that one apply your drawing, executed with lithographic ink, on lithographic transfer paper. Let the side of the tablet on which is the transferred drawing, be now dipped in weak acid and water, and then permitted to absorb a solution of sulphate of copper. By electro-metallurgy a deposition of copper can be made on all parts s ained with the sulphate. Ere this coating be too thick, let the tablet be removed from the vessel in which this last operation has been carried on, washed *carefully*, dried, and a mixture of isinglass and gin be poured on it: its redundancy be gently blotted off with blotting-paper till the surface be level (*i. e.* the copper lines and isinglass cement be of the same height), again, let the deposition take place, and again its succeeding operation, after which let common black lead be rubbed over the whole surface; and the deposition being renewed, a copper mould, from wh ch a type metal block may be subsequently cast, is now formed.—*Another method.*—Draw with a pen dipped in warm isinglass coloured cement, and when your drawing be dry, for an instant expose it to steam, and then coat it with leaf gold. Proceed by electro-metallurgy, as in last method, and no cast is necessary.—*Athenæum.*

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXV.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. It were to be wished that some of those who profess to admire Palladio, would be at the trouble of specifying his particular merits and beauties by pointing out striking instances of them in his works. Instead of which they deal only in vague eulogium, which teaches nothing. Surely they do not mean to say that it would not be worth while to perform so good an office for their favourite, nor can we imagine that it would be either a difficult or a disagreeable one to themselves. On the contrary it would afford them the opportunity of dwelling upon his excellences one by one, while such analysis of them might perhaps enable them to detect, to a certain extent at least, the secret of his peculiar art in composition. Neither would the task be at all superfluous, because I have met with others besides myself, who have confessed that they have not only been struck by egregious faults and solecisms in Palladio, but have been utterly unable to perceive any counterbalancing merits in him,—at the best no very striking beauties. For my own part I should say there is scarcely any work of Palladio's which does not afford an instance of something or other tasteless or faulty. By no means do I intend to deny that there are many useful elements to be derived from them, but as exhibited in his own compositions, they are either valueless, or else overpowered and neutralized by the rest.

II. It is likewise not a little remarkable that after Professor Hosking's bold attempt "to disabuse the public mind as to the merit of the work of Vitruvius," not only the public but professional men should continue to speak of it with implicit deference as before, and without attempting in turn to vindicate it from the aspersions so cast upon it, just as if the opinion put forth in such diametrical opposition to their own, had been given to the world anonymously in some obscure newspaper paragraph, instead of proceeding from an authoritative quarter, appearing in a treatise in the Encyclopædia Britannica, afterwards published separately, as a manual for students, consequently likely to prove extensively mischievous—at least in the opinion of those who still continue to "swear by Vitruvius," looking upon him as an infallible oracle. If such persons are perfectly sincere—which is somewhat problematical—their silence argues a great want of moral courage, since they patiently allow their oracle to be treated with contumely and indignity, without reproving the offenders:—unless indeed it be by merely affecting to sneer "at the small fry of critics who carp at Vitruvius." Such cool contempt may look very magnanimous, but it is in reality little better than cowardice, and a virtual acknowledgment that the less the merits of Vitruvius are inquired into, the better for him and his admirers. It is not denied that his writings have some interest, but then it is almost entirely in a philological point of view. They may occasionally help to elucidate archæological facts; but as far as the study of the art is concerned, they require to be elucidated by means of the other more satisfactory and more copious sources of information now opened to us. Perhaps it would have been a blessing to architecture had they never been discovered, for they have undoubtedly exercised a baleful influence on the Italian school, since had it not been for the blind deference paid to them, it is probable that on the revival of Roman architecture, the great masters would have freely imitated the orders of antiquity, instead of cramping the art, by establishing positive rules for each, and by endeavouring to make them conform as nearly as possible to the *recipes* given by Vitruvius;—in contradiction to that license—if it must so be termed, which manifests itself in actual examples—not those afforded by buildings alone, but by detached specimens and fragments, some of which are infinitely more valuable as artistical studies. Would Vitruvius help us to the Tivoli Corinthian, or to any of those varieties of the Ionic capitals, &c., which we meet with in Piranesi's "Magnificenzes"? Vitruvius and the Italians who have given us their codes of the orders, would reduce each to a single *pattern*: Doric, Ionic, and Corinthian, must each be put into its respective uniform, the precise cut of which is established by their martinet regulations, which, like the laws of the "*Maids* and *Parsons*" as Hook calls them—are to remain unaltered.

III. In this country architecture—or at least the study of it, seems to be just now marching at quick pace—backwards. While the Institute is forming a collection of the various editions of Vitruvius, the Royal Academy Professor is instilling some very odd notions into his audiences;—of course quite orthodox, since he himself must be looked upon as the very centre and fountain of orthodoxy; nevertheless far from being of the most enlightened kind, or manifesting a genuine *Catholic* love of the art. Wren seems to be the god of his idolatry—the master to whom he would refer us at the present day as the standard and compendium of architectural excellence. He claims our admiration not only for St. Paul's,—which we most readily concede, but for every other production of Wren's, although the majority of them possess no beauty whatever, but on the contrary display utter want of taste, and scarcely any invention.

IV. I am sometimes inclined to wonder, not that architecture should not be cultivated as a mere study, but that it should have any volunteer followers at all, for the silly trifling, the dulness, the pedantry, the bigotry, the extravagant galimathias, the downright nonsense, one has either to *wade* through, or else *evade* by skipping over,—are enough to disgust people with most treatises on architecture. As a mere vague, indistinct poetical analogy, something of the kind may be fancied to exist between architecture and music; but to adopt such speculations seriously as Vitruvius suggests—although he has not explained *how* we are to set about doing so, is sheer extravagance—a will-o'-the-whisp chimera, a delirium of the intellect. A thousand other analogies just as much to the purpose, just as substantial, and not a whit more whimsical might be traced by any one who chooses to be at the trouble of doing so. For instance, I myself would engage to show the analogy between Architecture and Cookery much more clearly and explicitly than has hitherto been done in regard to that fancied to exist, between Architecture and Music. The fantastic opinions promulgated by some in regard to architecture, convince us that Swift's Laputa is no caricature—quite the contrary, for the idea of extracting sunbeams from cucumbers, or of applying trigonometry to tailoring, seems perfectly rational compared with Michael Angelo's queer crotchet—viz., that a knowledge of anatomy is indispensable to the architect; or with the crazy metaphysical rhapsodies of Padre Georgi and his "Platonic principles" in architecture! what lunatic reveries!

V. Among the very queer things which have fallen from the Professor's lips during his course of lectures, may be reckoned, his admonition to students to avoid aiming at the Picturesque in architecture. Without going any further, it would be sufficient to remark that the advice, however salutary, is perfectly superfluous, for whatever else may be alleged against modern architecture and architects, it is quite impossible to lay picturesqueness, or the aim at it, to their charge. On the contrary we see building after building erected, which are remarkable for nothing so much as the entire absence of all picturesque quality, so that if not amenable to criticism when examined by standard rules, they are quite spiritless and insipid. Even allowing that the advice was intended chiefly as a caution to the junior students, to guard them from the error of attending chiefly to such effect, and overlooking more important considerations,—it does not seem to be of the soundest and most wholesome kind. If the architect intends to become more than a builder, we should say, it is highly important that he should begin to cultivate his taste, to exercise his fancy as soon as possible. For if the imagination is to be restrained until the judgment shall have been matured, and until proficiency in practical knowledge shall have been attained, the probability is that there will then exist no imagination to be brought into play. To expect that they who begin as plodders will end as artists, is to expect the order of nature will be reversed—that after-life will prove the season of genial inspirations and high imaginings which never came across the mind in youth—and that after years of torpidity and dulness, the powers of fancy will burst forth with peculiar vigour. Methinks it would have been greatly more to the purpose had the Professor exhorted his pupils to endeavour to secure picturesque quality in the first sketches of their ideas upon paper, and then rigorously to revise them, correcting, sobering down, maturing, until the whole should satisfy the judgment as well as the fancy. If, indeed, the principal or sole merit of a design consists in its being picturesque, it will be more or less defective in more essential points: yet that quality in itself is not a defect, unless it can be shown that every thing else has been sacrificed in order to obtain it. I almost wonder the Professor did not follow up his admonition by a fling at that specimen of the picturesque in architecture which his predecessor both at the Academy and the Bank of England,—has given us in the North-west angle of the last-mentioned building. And except that, there is hardly another instance about town, where picturesque expression has been studiously brought in, unless it be in that very strange piece of architecture in the Assurance Office in the Strand, which the Professor should have held out *in terrorem* to his pupils, and held up in derision to his audience generally.

VI. Some one, I find, has been liberal enough to say of me in a newspaper critique on one of the late numbers of the "Civil Engineer," that if I wanted a motto, I might take "Castigat Ridendo" for the purpose, and that my remarks, though "exceedingly pleasant, are also confoundedly caustic, original withal, and full of matter." This is certainly encouraging, and holds out to me the hope that the continual drippings of my pen may in time make impression somewhere, and wear away some of the prejudices against which they are directed. Inveterate errors—errors, moreover of a *respectable* kind, and sanctioned by what passes with the world for paramount authority in all such matters—are not to be exploded in a day, but are rather to be worn away by constant filing. The great thing to be accomplished, if we would advance architecture, is to diffuse a taste for it among the public. For this no stone should be left unturned; nevertheless, it is precisely the very point which is never taken into consideration at all. And why? because none, be they either individuals or societies, feel their own immediate interests concerned in it. It is all very well to string together a parcel of pompous words and phrases about encouragement of art. But it is all moonshine—all gammon! for it has not even the poor merit of sincerity, being no less hollow that it is shallow.

VII. Professor Hosking does not hit the right nail on the head, when he lays so much stress upon the importance of practical knowledge. At any rate, as far as architecture is concerned, it is not there that our deficiency is most apparent. Not a few buildings might be enumerated which, though perfectly irreproachable in respect to construction, are altogether unsatisfactory, absolute nullities and naught, if we consider them as productions of art—and were we not to allow them to be such, their authors would be ready to *Cardigan* us. There are people, nay, professional ones, who affect to hold all that belongs to taste—to the æsthetical part of architecture, as matter of indifference. Possibly they may be sincere—the greater probability is that they are not; but if they are both sincere and consistent, with what utter scorn must they look upon—as what arrant rubbish must they regard, nearly all that has been written upon architecture, whether by Vitruvianists or Palladianists, by Greeks or Anti-Greeks, by Goths or Anti-Goths. How must they in their hearts despise all the wordy strife and contentious babblings and gabblings with which some square miles of paper have been covered!

CHEETHAM CHURCH, &c.

Sir—It is to be hoped that the example set by your correspondent who has furnished the account of the church at Cheetham will be followed by others; for similar descriptions of buildings lately erected or in progress in different parts of the country, would prove valuable information, if only as directing inquiry to what is deserving notice. And since architects themselves are, it seems, very backward in communicating intelligence of the kind, all the more desirable is it that it should be volunteered by other parties. Still, though the description here mentioned is sufficiently full and satisfactory upon the whole, the writer has omitted to state the dimensions of the building, to which he might have helped us by some sort of calculation in round numbers, though he might not be able to tell the precise admeasurements. Neither would it have been amiss had he informed us at what time the church was began and completed, for both dates and dimensions are rather important items in all architectural descriptions, quite as much so as that of cost, which last, however, seems to be invariably the uppermost consideration of all with Mister John Bull.

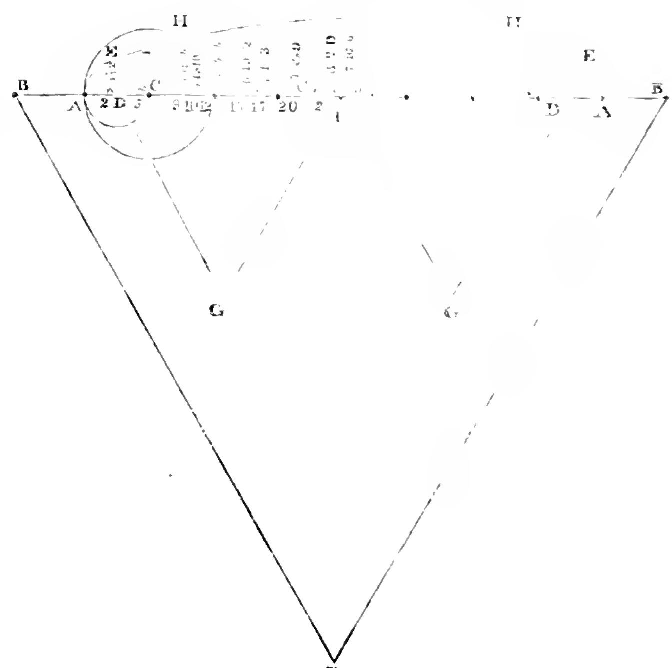
While I thank the writer for his communication, I must say there is one expression which I think he had better have left out, for I can readily perceive no modesty whatever in his affecting to call himself "an incompetent person," at the very same time that he adds "architect" to his name; for unless it plainly appears to the contrary, it may be presumed that a professional man is tolerably competent to draw up an architectural description.

H.'s strictures on the "Banks," &c., at Liverpool, contain so much sound criticism, and are written with such spirit and ability, that I sincerely hope you will be able to prevail upon him to extend his observations to other buildings in that town. If he choose to do so, he might probably be able to make some communication relative to the intended "Assize Courts," and "St. George's Hall," both which almost seem to be abandoned, at least for the present. It is, therefore, desirable to know why so much fuss should have been made at all, if nothing is to come of it.

You will think that I am going to review nearly all the articles in your last number, still, I must be allowed to say a word *en passant* to Mr. East, and without expressing my opinion on his paper generally, observe that it would have been not at all less to the purpose, had it specified a few of Campbell's works, and instanced in them those peculiarities which he notices. He might, too, at the same time, have enlightened such blockheads as Candidus and myself, by pointing out in what buildings or designs of Palladio's we are to discover that "grand simplicity and rich excellence"—*risum teneatis!*—which he claims for him. I have spent half a day in looking over a set of his works, yet, hang me if I can find out any thing of the kind in any one of them. Mr. East will, perhaps, say that then I fairly deserve to be hanged without benefit of clergy. I am, therefore, resolved to hang—no, I don't mean to hang myself, but to *suspend*—my pen for the present.

I remain, &c. &c.,
John Croker.

ON THE CURVATURE OF THE ARCHES OF THE BRIDGE OF THE HOLY TRINITY.



Sir—In looking over some old plans, I fell in with my solution o the curvature of the arches of the bridge of the Holy Trinity at Florence, as far back as January, 1826. I was induced to attempt this solution in consequence of a paper published in the Quaterly Journal of Science, edited at the Royal Institution, by Samuel Ware, Esq., April, 1823, Vol. 15, at the same time having a bridge to erect over the College River, where the situation required a bridge of similar construction.

"ON THE CURVATURE OF THE ARCHES OF THE BRIDGE OF THE HOLY TRINITY AT FLORENCE. BY SAMUEL WARE, ESQ.

"To determine the curvature of the arches of the Most Holy Trinity, erected over the Arno at Florence, by Bartolommeo Ammanati, is a problem which still occupies the attention of antiquaries, mathematicians and architects. Some account of the interest this question has excited will be found in Ferroni's tract, entitled 'Della vera curva degli archi del Ponte a S. Trinita di Firenze: discorso geometrico-storico,' inserted in the 11th vol. of the 'Transactions of the Societa Italiana delle Scienze.

"When it is observed that the curvature of these arches affords the flattest roadway and the greatest waterway, with the smallest quantity of material, of any stone bridge ever constructed; and taking into consideration that cast iron is ten times stronger than marble, and twelve times stronger than common stone in compression, and that the vault of this bridge is less in depth from intrados to the extrados than any iron bridge hitherto built, with relation to the radius of curvature at the vertex, we shall not wonder that the inquiry should be continued until a satisfactory solution be obtained."

The annexed construction gives every ordinate to an extreme exactness when executed with accuracy, as shown by the figures in the annexed diagram. Also the chord of the smaller arch of 45° 15′ 4″

by the same construction gives 7° 3′ 5″ as the versed sine. *Vide* Quarterly Journal of Science.

I am, Sir,
Your very obedient servant,
EXPERTUS LOQUI.

Wooler,
25th January.

GEOMETRICAL SOLUTION.

Construction.—The span or chord AA being given, subdivide it accurately into eight equal parts. Add to each extremity of the chord AB also an equal part, the semi-diameter of the piers. Bisect the extreme divisions of the chord AC in D, and with DA as a radius, and D as a centre, describe the circle AEC. Then, from the centre of the chord F to the point D as a dimension, make the equilateral triangle FGD, and continue the line GD to E—E is the point of intersection. Next, with CA as a radius and C as a centre, describe the circle AH; then take AF (one half the chord) as a radius, and G as a centre, describe the arc EH—H is also a point of intersection. Lastly take the base line BB as a dimension, and make the equilateral triangle BIB, and with HI as a radius and I as a centre, describe the arc HH, which gives the required curve.

WOOLF'S DOUBLE CYLINDER ENGINE.

SIR—An estimate has been given of the power of Woolf's double cylinder rotary engine, at page 50, February 1841,—on assumed conditions of steam pressure, so much at variance with those which could occur, that I conceive further observations are required to elucidate this subject.

In regard to the Cornish engines, perhaps it would be difficult to assign to each their relative position in the scale of merit, in the introduction of the improvements by means of which so great an increase of work has been obtained in Cornwall.

Woolf's advocates may fairly point to the reported duty of his engines, which for a long period maintained their position at the head of the best—at present neither his engines or boiler are in use. Trevithick, who was equally well known as an advocate of high steam, went to America just at the critical period when the results of the rivalry established among the mining engineers had began to develop itself. His boilers still keep their ground, and have afforded other engineers the means of working high steam expansively in Watt's engines, with an effect far exceeding that as yet obtained from Woolf's engines.

In the former the calculations for expansion are well known—but in the latter the original volume of steam cut off is driven into another cylinder during expansion—while the mean pressure of this steam reacts against the full pressure steam by which the smaller piston is impelled.

The admission however of the steam into the small cylinder may be cut off at any portion of the stroke, and worked expansively during the remainder, and may then be further expanded in the large cylinder, so that the assertion that "the capacity of the smaller cylinder naturally determines the quantity of steam which the boiler must supply," is untenable.

The only safe assertion respecting the steam pressure in the cylinder would be that it is lower than that in the boiler, and the difference was only considerable, especially in Woolf's practise, from his opinion in favour of wire-drawing high steam, and the small allowance of steam room in his boilers.

Supposing the safety-valve of a boiler loaded with 10 lb. per square inch, it is not probable that the constant total pressure in the cylinder would exceed 40 lb., including atmospheric—that is, 14·75 + 25·25 lb., having a volume of about 670 for one of water. Had the steam been expanded at 40 + 14·75 = 54¾ lb. the volume would have been 520 for one.

During expansion on the given conditions of the respective cylinders, the mean pressure of the steam would be about 17 lb. per square inch on the large piston, with a reaction of 17 lb. per square inch on the smaller piston—against the pressure of 40 lb. full pressure steam on the other side—hence

$$\text{Small cylinder } \frac{207{\cdot}39 \times 40 - 17 \times 176{\cdot}34}{33{,}000} = 25{\cdot}5 \text{ H. P.}$$

$$\text{Large cylinder } \frac{660 \times 17 \times 212}{33{,}000} = \quad 82{\cdot}28$$

Absolute power - - -	107·78
Friction = ⅓ - - -	35·92
Effective power - - -	71·86

Taking similar conditions of water evaporation, and cubic feet of steam required, we should have $\frac{16800}{670} = 25$ cubic feet of water per hour, and at 8 lb. of water from 1 lb. of coal, the consumption would be about 2 lb. of coal per horse power per hour.

Numerous causes might produce a consumption of 4 or 4½ lb. of coal per hour, the difficulty would be the reduction of the coal expenditure to the quantity theoretically calculated as sufficient. Instead of low pressure engines, the proper standard for Woolf's, are Watt's engines working high steam expansively, both using similar boilers and coal.

I am not aware of any trials under these conditions, which can be considered conclusive in regard to their relative merits.

I remain, your obedient servant,
Y.

March 11.

CONSUMPTION OF COKE—GLOUCESTER AND BIRMINGHAM RAILWAY.

SIR—In Whishaw's Railways of Great Britain, page 30, there is a statement taken from a paper by Capt. Moorsom relative to the performance of a locomotive engine imported from the United States, that in seven journeys of 596 miles up to Birmingham, the engine conveyed 682 tons gross, and consumed 177 sacks of coke (1½ cwt. each), and in seven journeys of 596 miles down from Birmingham, the same engine conveyed 629 tons gross, and also consumed 177 sscks of coke.

Mr. Whishaw observes, "Thus the consumption of coke, according to this statement, taking the average of the loads up and down, was at the rate of only ·007 lb. per ton per mile!!"

The meaning of Capt. Moorsom's statement seems to be that the engine passed over twice 596 miles with a mean load of 93·64 tons, and consequently her consumption would be ·541 lb. of coke per ton per mile.

It may not be difficult to account for Mr. W.'s erroneous figures; if $\frac{682+629}{2}$ had been the mean load carried, the consumption would have been about ·07; and a mistake in the position of the decimal is not uncommon. I cannot account for the two notes of admiration so readily, as they prove that his attention was called to extraordinary apparent economy of the consumption of coke.

I remain, Sir,
Your obedient servant,
Y.

March 11.

MONUMENT ERECTED AT LIMERICK TO THE MEMORY OF THE LATE VERY REV. DR. HOGAN.

WE were yesterday favoured with a view of the monument just erected in the parish chapel of St. Michael, to the memory of the late very excellent and justly esteemed pastor; and we freely acknowledge that, in classic chasteness of style, correct architectural proportions and superior beauty of execution, the monument surpasses any thing of the kind heretofore seen in this part of the country, and probably not inferior in these qualities to any other specimen of modern sculpture in the Kingdom. The appearance of this memorial to departed worth is at once imposing and elegant, and the eye loves to rest with pleasure on its sublimity of conception, the elaborate beauty of its detail in the various compartments, and the superior finish of the workmanship, from the most minute object to the most prominent, which is a figure of the Archangel Michael. Well may the subscribers be proud of such a lasting record of the virtues of him whom it commemorates, and happy may the highly gifted and eminent artist feel, the production of whose taste and ability it is. Mr. Bardwell, of London, is that gentleman, and at present engaged in the erection of that magnificent edifice, Glenstall Castle, in this county.

It is a mural monument, of Gothic architecture, at the period of the 15th century, and the details are principally taken from the Chapel of Henry VII., in Westminster Abbey; also, from the Chapel of Magdalen College, Oxford. The monument, which partakes somewhat of the character of a shrine, is apparently borne aloft, or supported, by four angels, correctly copied from the works of Wainfleet, Bishop of Winchester, and founder of Magdalen College. One of the angels bears a shield, another a book, another a censer, and the other a lily—this last, which is particularly beautiful and true to nature, was a favourite emblem of Wainfleet's, and figures in many parts of Magdalen College. The design consists of three compartments, divided by boldly projecting buttresses terminating in richly crocketted finials, subdivided by rich and elaborate tracery into smaller ones. The whole design may indeed be considered allegorical, consisting of a number of beautiful figures, each having reference to the spiritual duties and pious characteristics of the deceased clergyman. For example, one of the figures represents St. Peter as Prince of the Apostles; another St. Patrick, the patron of Ireland; another St. Roche, a figure emblematical of our short pilgrimage in this world; while the patron saint of the chapel in which it stands, and in which the deceased officiated for 26 years, occupies the centre compartment, exhibiting a drapery containing the inscription.

The exquisite beauty of this figure is remarkable and is worthy of earnest attention, the spreading pinions, the calm angelic sweetness and dignity of the countenance, and the serpent writhing in agony beneath his foot crushed to the earth by his delegated power, all unite to form a combination of grace, elegance, and skill in design and execution which cannot fail of raising in the mind of the spectator the highest admiration. The accuracy and ability displayed in the portraiture of the serpent, especially about the head, are wonderful: in the three niches at the other side are two figures of alcolites, one bearing wine and the other bread, and in the other the figure of a mitred abbot in his ecclesiastical costume, to continue the allegory as to the station and rank of the deceased. Over these objects, the cornices are most elaborately sculptured and crowned by a rich border, with the usual finish of the period, a strawberry leaf and ball, with the Tudor flower interspersed. The monument, which is all of the purest white Italian marble, is projected on a magnificent black slab, 13 feet by 7, from the Ballysimon quarry, in the neighbourhood of this city, and its erection has been, this day, completed by Mr. Garvey, of Catherine Street, under the direction of the artist, Mr. Bardwell, who has been most particular in seeing to its security and completion. —*Limerick Chronicle.*

NEW INVENTIONS AND IMPROVEMENTS.

IMPROVEMENTS IN STEAM ENGINES AND PADDLE SHAFTS.

Henry Trewhitt, of Newcastle-upon-Tyne, Esq., for improvements in applying the power of steam-engines to paddle-shafts used in propelling vessels. Enrolment-office, February 7, 1841.

These improvements consist in a new method of applying the crank-pin of paddle-shafts, so that one or both of the paddles may be disconnected or connected with the engine with great facility. For this purpose there is on each of the paddle-shafts a narrow cylinder, with a groove on its periphery, to receive a strap which is attached to the crank-pin that drives the paddle-shaft. The other end of the crank-pin is keyed into the crank of the middle shaft. In order to connect the paddle-wheel with the engine, the strap is made to bind tightly upon the narrow cylinder, and is disconnected by being loosened, in the following manner. A cross-head passes through slits in the end of the strap, and is fastened to a cushion resting on the narrow cylinder, and curved on its under surface so as exactly to fit. When the paddle-shaft is to be connected to the engine, the cushion is made to press upon the narrow cylinder by a wedge-shaped bar, which enters between the back of the cushion and the cross-head; this causes the strap to bind tightly upon the cylinder, and forms the connection required. On withdrawing the wedge-shaped bar, the strap becomes loosened and the paddle-shaft is disconnected from the engine. The claim is to the mode described of applying the crank-pins to paddle-shafts.—*Mechanics' Magazine.*

IMPROVEMENTS IN RAILWAY WHEELS, RAILS, AND CHAIRS.

Andrew Smith, of Princes-street, Leicester-square, and of Mill-wall, Poplar, Engineer, for certain improvements in carriage wheels, rails, and chairs, for railways. Enrolment-office, February 7, 1841.

The improvement in wheels consists in the application of a wrought iron tire, having a right-angled groove turned out in the middle, corresponding to the rail which constitutes the second part of these improvements. The depth of this groove is to be proportionate to the size of the rail, and forms a flange within the surface of the tire, tending to keep the wheel in its place upon the rail. The rails are square bars of iron, the sides of the squares being about one-third wider than the depth of the sides of the groove in the tire of the wheels, for the purpose of preventing the wheels from coming in contact with the chairs and sleepers. These rails are laid in grooves cut in wooden sleepers, and present one of the angles of the square upwards, corresponding with the angular groove in the tire of the wheel. The chairs are made of wrought or cast iron; they clip the sides of the rails in a dove-tail form; and are let into and bolted down to the wooden sleepers. The rails are each 12 feet long, by 2¼ inches square, and the chairs are placed in the middle and at the junctions of each rail. The claim is, 1. The right-angled grooves in the tires of the wheels of railway carriages, instead of an external flange.—2. The adaptation of common square bar iron, or of iron made in a square form, let into a wooden sleeper.—3. The chair, for connecting, and fixing, and fastening the rails.—*Ibid.*

IMPROVEMENTS IN LIME AND CEMENT.

Charles Smith of Exeter, Devon, builder, for improvements in the manufacture of lime and cement, or composition. Enrolment-office, February 27.

Claim first.—The mode of calcining lime or cement, or composition, by means of kilns, so formed, that the charge in the upper part shall be calcining, whilst the lower part of the charge is cooling; and in cooling, the heat therefrom passes to the upper part of the kiln.

The heat from coke ovens, furnaces, &c., is admitted into the kiln by flues which enter the kiln half its height from the ground, and the heat rising upwards calcines the upper part of the charge; whilst the lower part of the charge which has been calcined, is cooling, the heat arising from it assists in the calcination of the upper part. The lower part of the charge as it cools is raked out at the bottom of the kiln, and the upper part descending, fresh lime is added at the top of the kiln.

Claim second.—The mode of calcining lime and cements in retorts or ovens when in connection with a closed chamber, where the matters can be cooled before being brought into the atmosphere, and also the carrying off the gases or vapours, so as to apply them to a variety of useful purposes. The lime and cements are calcined in ovens which communicate with a closed chamber, in which the lime and cements, after being calcined, are cooled before they are brought into the atmosphere. The gases or vapours are carried off from the ovens by pipes provided with stop-cocks, into suitable vessels provided for receiving them.

Claim third.—The application of the heat of lime-kilns to the purposes of evaporating fluids in suitable boilers or pans, as herein described. The heat arising from the kiln is applied by means of flues to the heating of boilers or pans for evaporating fluids.

Claim fourth.—The mode of slacking lime in chambers with carbonic acid as herein described. The lime is slacked in a chamber, into which the carbonic acid arising from the kiln is admitted by means of valves communicating with the flue.

Claim fifth.—The mode of manufacturing lime by re-calcining it after dry slacking. The lime after being slacked as above described, is placed in the oven and again calcined.

Claim sixth.—The mode of manufacturing lime by partially calcining limestone in a kiln in order to convert it into sub-carbonate, and after cooling and grinding again to calcine it, whether separate, or combined with other matters, for making cement. This claim fully describes itself.

Claim seventh.—The mode of making cement by saturating sulphate of lime with ammoniated liquid, or other matters, as herein described. The patentee grinds sulphate of lime, or gypsum, into a powder, and covers the floor of the oven three inches thick with it. The oven is then closed, and the charge remains for four hours. It is then placed in a cistern and covered with purified liquor prepared from the ammoniated fluid formed in the manufacture of coal gas, commonly called gas water. When completely saturated it is spread over the floor of the oven and dried. It is then taken out, and a fifth part of slacked lime is added to it, after which it is ground and placed in the oven for the same time as before. It is then fit for use.

Claim eighth.—The combining lime and cements with ground calcareous matter, or stones, in substitution, or in aid of, silex, or other matter. The lime is mixed with ground calcareous matter, and burnt in the oven, after which it is fit for use.

Claim ninth.—The mode of preparing lime for use by applying soap, with or without glutinous matter, and also the method of using hot tools for finishing and polishing cemented surfaces. Two parts of ground marble are mixed with one part of fine slacked or ground lime, with the least quantity of water possible. This is done two or three days previous to using the same, but it is tempered once or twice a day with a beater or other tool. The patentee next takes one pound of soap, and dissolves it over a slow fire in about six quarts of water, occasionally adding two ounces of glue or other glutinous matter to the same, by which means the cement is rendered more tenacious. He takes the composition prepared as above, and adds to it the colour, to form the tint required for the ground colour, and brings it to the consistence for use by pouring into it the soapy solution, mixing it well, and applying it in the manner that stucco is at present done. When it is done a highly burnished hot metal tool is passed over the surface, which will unite the whole, and form a good polish.

Claim tenth.—The mode of preparing cement from lime, by means of oil and water, with or without other materials, as herein described. To any number of gallons of clean water add as much fresh burnt lime as will when slacked bring it to a semi-fluid consistency. When it is half slacked add as many quarts of oil as there are gallons of water, and stir this well together until the whole is properly mixed. Then strain it through a fine sieve, and when cool it is fit for use. It is applied in the same manner as when plastering with stucco.

Claim eleventh.—The combining aluminous earths and ground clinkers, or slag, or scoria, from the smelting furnaces; and the forming and burning of tiles thereof. Also the forming of tiles or burnt rough surfaces to be used in substitution of laths, to receive cemented surfaces as herein described. The tiles are made of three parts good aluminous earthy matter, mixed with one part of ground clinkers &c., from the smelting furnaces, and when properly tempered they are made, dried, and burnt in the same manner as roofing tiles. They are made rough on one side so that the composition applied may adhere freely in the same manner as the pricking up coat, thus serving the double purposes of laths and the pricking up coat.

Claim twelfth.—The mode of treating articles made of lime or cement, and calcareous stone or earth, by placing them in chambers with carbonic acid. The articles previously wetted with lime water are placed in the chamber mentioned in the fourth claim, and exposed to the action of the carbonic acid, by which they acquire great hardness.—*Inventors' Advocate.*

STEAM ENGINE REGULATOR.

Benjamin Hick, jun., of Bolton le Moors, Lancashire, engineer, for certain improvements in regulators or governors, for regulating or adjusting the speed or rotary motion of steam-engines, water-wheels, and other machinery. Entered at the Petty Bag-office, February 27.

This improved governor is applied to the throttle valve of steam engines, in place of the ordinary pendulum governor. The ordinary iron standard or frame of the governor, is placed as usual over the crank shaft of the engine, on which is fastened a bevel wheel that drives a pinion attached to an upright spindle or shaft; by this means a rotary motion is communicated to the spindle, which revolves in suitable bearings in the frame. The upper part of this spindle is cut into a screw, on which a bush or nut, having an internal screw, works; this bush, having two arms extending from it, to each of which is attached a vane: and the bush is connected to the throttle valve of the engine by links and a swivel, and connecting rods and levers, in the usual manner. If the crank shaft overruns or increases its ordinary velocity, it will cause the bush to rise up the spindle, and by means of the connecting rods and levers, partially close the throttle valve: on the contrary, if the crank shaft decreases its ordinary velocity, the bush will descend, and so open the throttle valve wider, in order to admit an additional quantity of steam to the engine. The patentee does not confine himself to the above, as the parts may be varied to suit circumstances.—*Ibid.*

APPARATUS FOR PREVENTING SHIPWRECK.

A few months since we gave an account of an interesting attempt made by Mr. Page, the superintendent of our Harbour Works, for simplifying Captain Manby's plan for relieving vessels in danger of shipwreck. It is with the greatest pleasure that we have to state that Mr. Page has *tested* the value of his efforts by saving a vessel, to all appearance, destined to inevitable destruction. About one o'clock P. M., of the 13th of February, the schooner *Leighton*, Jones, master, was seen making for this port, and driving with a heavy sea right for the north side of the harbour, where we have witnessed many a wreck with loss of life and property. The sea being at this time so heavy, and the boat, with the pier rope, being unable to get through, in consequence of the surf, the vessel struck on the North Bank. The situation of the vessel was now so critical, and the breakers surrounding so violent, that no boat attempting to relieve her could live. Under these circumstances, Mr. Page brought the twelve pounder belonging to the Harbour Works to bear upon her, and at the first discharge, succeeded in conveying a rope across the breakers, which passed fairly over her rigging. To this rope, a hawser was fastened by those on the pier, which, being hauled by the crew on board, sufficiently steadied her, and the result was the vessel was saved. We feel it our duty to give publicity to this circumstance, feeling perfectly confident that were it not for the rope conveyed by the carronade, she would either have been a wreck, or have received considerable damage. James Davies, Esq., the owner, was present, and seemed not a little pleased at the result of the first trial of Mr. Page's experiment.—*Carmarthen Journal.*

Since the appearance of the above paragraph, the above plan has been again adopted with complete success, but with such variation, as to give it additional value, by showing the versality of its application. On the 23rd ult., the schooner *Nanteos*, Griffiths, from London, appeared before this port, but the breakers were so high, that it was impossible for any boat to go out to assist her in. On this occasion the *carronade* was fired from off the pier, which carried the *plug* beyond the breakers,—this was picked up by the boat from the Nanteos, and a communication was immediately made with the shore, and the vessel came in without any difficulty.

The advantage of the *plug* over a *shot*, may be seen on occasions like the present,—had this been a *shot* connected with the line, it would have sunk, but the *plug* floated, and was easily picked up by the boat from the Nanteos.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

Annual Report.

The Council of the Institution of Civil Engineers, on resigning the trust which has been confided to them during the past year, invite the attention of the Annual General Meeting, and of all who are interested in the progress of practical science, to the following report on the discharge of their various duties, and on the general nature of the proceedings of the past year.

The annual report of the council of several preceding years has dwelt in considerable detail not only on alterations in the ordinary business of the Institution, and on the introduction of measures which might tend to the convenience of the general body, but also on changes of a more important character, affecting the constitution and permanent stability of the Institution itself. The year which has now past has not been marked by any features of this nature. The principal duty of the council has been to carry out and persevere in the practice and regulations established during previous years, which have been found to contribute so much to the rapid growth and increasing value of the Institution.

But, though the past year may not have been marked by extensive changes or by the introduction of new regulations, it has been characterised by events of great interest, and the proceedings of the last session surpass in extent those of any previous year. The extended importance of the Institution has imposed an augmentation of duty and responsibility on your council, and they have laboured so to direct the affairs intrusted to them, that the discharge of those increased duties might be attended with a corresponding elevation in the character of the Institution, and that their successors in office may realize a still further progress towards that eminence which is already in some measure attained.

Among the various duties which devolve on your council, that of disposing and awarding the Telford premiums is of the highest consequence, and on the proper discharge of which much of the permanent success of the Institution will depend. The council, deeply impressed with this, have given their most careful consideration to the subject; they would direct your attention to the following notice of the premiums, and of the respective communications for which they have been awarded.

In the annual report of the last session, the council stated that it would be one of the earliest duties of their successors, to consider in what manner the benefits conferred by your member Mr. Parkes on practical science, by the communications then alluded to, could be most appropriately acknowledged; and the present council, concurring most fully in these sentiments, are of opinion that as no papers have hitherto been received by the Institution, exhibiting so much originality, labour, and ingenuity, in dealing with the facts presented to his notice, combined so essentially with practical utility, they are warranted in conferring on Mr. Parkes the highest honour which the Institution has in its power to bestow. They have awarded, therefore, the Telford Gold Medal to Mr. Parkes, for his communications on "Steam Boilers and Steam Engines," which are now published in the first and second parts of the third volume of the transactions. These papers and the discussions to which they gave rise, occupying as they did the attention of several of your meetings, together with the interest which they excited, must be fresh in the recollection of all who were present. It will, therefore, be unnecessary to dwell particularly on their contents; but, inasmuch as the highest honour of the Institution has been awarded to them, an honour which (it must be remembered) has been but once previously conferred, the council feel it to be a duty which they owe to the Institution, to themselves, and to the public, no less than to the author, to point out (as has been partially done in the report of the last year) some of the principal features in these communications, and the peculiar benefits which are thereby conferred on practical science.

These communications are the continuation of the labours of the author, which commenced with the paper on the "Evaporation of Water from Steam Boilers," published in the second volume of the transactions, and for which a silver medal was awarded on a previous occasion. The first communication, forming the subject of the present notice, relates especially to steam boilers, respecting which many well-ascertained facts had been collected; but previously to Mr. Parkes devoting his attention to this subject, no clear and connected view had been given of the various facts, or of their relation to each other, and to the circumstances under which they are exhibited. When so represented, it appears that the peculiar circumstances under which steam boilers are employed and their corresponding qualities and characteristics in respect of construction, proportion of parts, and practical management, present certain quantities and relations, which exert a peculiar influence over the results connected with evaporation; and these being clearly developed and understood, indicate correctly the character of the boiler. Certain definite quantities, relations, or exponents, with other facts of paramount importance, such as the effect of the element time, or the period of the detention of the heat about the boiler, and various actions independent of the temperature of the fire, and tending to the destruction of the boiler, are here for the first time pressed on the attention of the practical engineer. In the second communication, the author traces the distribution and application of steam in several classes of steam engines. In the execution of this task, he is led into a detailed examination of various important questions: the best practical measure of the dynamic efficiency of steam—the methods employed to determine the power of engines—the measures of effect—the expenditure of power—the proportions of boilers to engines—the standard measure of duty—the constituent heat of steam—the locomotive engine—the blast and the resistance occasioned by it—the momentum of the engine and train, as exhibiting the whole useful effort exerted by the steam—and the relative expenditure of power for a given effect, by fixed and locomotive non-condensing engines. The bare enumeration of the principal subjects which have been carefully analysed and illustrated by the facts applicable to each respective case, will give some idea of the magnitude of the task here undertaken; and when, in addition, is considered the elaborate and extensive series of tables exhibiting the results and analysis of the facts collected and used in the course of the inquiry, the council cannot but feel that a more laborious task has rarely been accomplished. A peculiar feature of these communications, and one to which the council would particularly advert, is, that they are not of a speculative character, but present a detailed analysis of authenticated facts.

This analysis consists in separating and ascertaining the various results, and in referring them to particular classes, so that they may be readily applicable in practice. The merit of instituting and recording a series of observations upon a scientific subject is universally acknowledged, but the reduction of such observations so as to form a standard of reference to which the practical engineer may appeal, is a task of far greater difficulty, and its execution of far higher merit. It is in this eminent rank that the council would place these communications of Mr. Parkes.

The description by Mr. Leslie of the Harbour and Docks of Dundee, was also briefly adverted to in the last annual report, as one of those communications on which the Institution sets great value. It consists of a detailed account of the progress of the improvements projected by Smeaton, Telford, and others, in part carried into execution by the projectors, and completed under the author's own superintendence since 1832. The illustrations of the projected and executed improvements with the plans, elevations, sections, and details of the works of the docks, gates, quays, cranes, and machinery employed, occupy 36 sheets of drawings. To the copious history and description of these works is added an extensive series of observations on the tides. The determination of these facts for different parts of the globe, is a question of the greatest importance in physical astronomy, and the council would take this opportunity of pointing out the essential service which may thus be rendered by the engineer to the cause of science by his recording the observations which *he* has pre-eminently the opportunity of making. For this valuable record of an executed work, the council have awarded a silver medal, and a copy of the life and works of Telford.

A silver medal and the life and works of Telford have been awarded to your associate, Robert Mallet, for his communication on the "Corrosion of Cast and Wrought Iron in Water." This communication presents features of no ordinary interest to the engineer. The comparatively recent introduction of cast iron for the purpose of piling, for wharfs, &c., and of wrought iron in the construction of vessels, has rendered the subject of the action of water upon iron of peculiar importance; the British Association have, from time to time, granted sums of money for making experiments on this subject, and Mr. Mallet having been engaged in conducting these experiments, has selected from the very extensive series of results obtained by him, those conclusions which may be of service to the practical engineer. The most valuable portion of this communication consists of elaborate tables, which exhibit the results of the action of clear and foul sea and fresh water at different temperatures upon cast and wrought iron. Such being the general nature of the experiments, the results to which they lead, or the effects produced, present several remarkable characteristics, and it is found that the corrosive action of water and air combined, produces, on the surface of cast or wrought iron, a state of rust possessing one of five distinctive features, viz. uniform—uniform with plumbago—local—local pitted—tubercular; or some two or more of these in partial combination. The practical results which may be deduced from these tables are of the highest value to the engineer, and point to considerations of the greatest importance; thus the upper and lower strata of water, of different degrees of saltness and density, coming in contact with the same mass of iron, a voltaic pile of one solid and two fluid elements is formed, and under such circumstances the corrosive action is materially augmented; hence it follows as a practical conclusion, that the lower part of all castings used in such situations, should be of increased dimensions. Similar results, the knowledge of which is of great importance to the practical engineer, such as the rapid decay of iron in the sewage of large cities, of the bolts of marine engines exposed to the bilge water, and of boilers containing hot sea water, are referred to actions due to similar physical principles. The protection which metals receive from paint, or from the presence of various alloys, so as to obtain a mode of electro-chemical protection, such that, while the metal iron shall be preserved, the protector shall not be acted upon, is also referred to similar principles.

The council have also awarded a bronze medal and books to Mr. Charles Bourns, for his communication on "setting out railway curves;" to Mr. Chapman, for his description and drawings of "a machine for describing the profile of a road," and to Mr. Henry Renton, for his description and drawing of "a self-acting Waste-board on the River Ouse."

The communication by Mr. Bourns is an application of simple geometry, leading to practical results. In setting out curves recourse has been had to various expedients, but Mr. Bourns, in the propositions contained in this paper, has shown that, by the use of the common chain, an offset staff, and table of offsets, he is enabled to set out curves of any radius and flexure, with a facility and precision not generally attained.

The description and drawings of a machine for describing the profile of a road, is one of several communications on this subject, sent in accordance with the notice of subjects for competition issued by the council. Many of the arrangements proposed by the author exhibit considerable ingenuity, and though difficulties may exist in their practical application, the council think this attempt may be of assistance to others, who may have their attention directed to the construction of an instrument for similar purposes.

The description and drawing of the self-acting waste-board on the river Ouse, being an account of an executed work, is one of those communications which the council are most anxious to encourage by every means in their power. The drawing and description furnished by Mr. Renton are highly creditable to the talents of the author, and deserving of some special mark of approbation.

The council have also awarded books to the value of five guineas to Eugenius Birch, for his drawing and description of the machine for sewing flat ropes, in use at Huddart's rope manufactory. The rope machinery of Captain Huddart was, some time since, one of the subjects on which the council solicited communications; on that occasion two valuable sets of drawings were communicated, the one by Mr. Dempsey, the other by Mr. Birch. The subject of the present communication was not included in either of the preceding, but Mr. Birch, desirous of availing himself to the fullest extent of the liberality of Mr. Cotton, the then proprietor of the machinery, and of carrying out the views of the council, has devoted much time and labour to placing in the Institution, an exact record of every thing connected with this interesting machinery.

Premiums of books have also been awarded to Mr. Maude, for his "Account of the Repairs and Alterations made in the construction of the Menai Bridge, rendered necessary by the gale of January 7, 1839," and to Mr. Andrew Burn, for his drawings of a "Proposed Suspension Bridge over the Haslar Lake." The council would point out these instances of the fulfilment of the engagements entered into on election, to the attention of the other graduates of the Institution, who have similar opportunities, but who have not hitherto kept their promises. It is the desire of the council to obtain an exact record of works that are projected or in progress, and such records are peculiarly adapted to compete for the Telford premiums; Mr. Maude and Mr. Burn, with proper permission, have availed themselves of the facilities afforded them, and the council trust that the premiums now awarded, and the marks of approbation here expressed, will stimulate others to avail themselves of like opportunities. The authors of such communications will thus most materially contribute towards promoting the interests of the Institution, and to their own qualification for future employment and advancement in the profession.

The Institution has received during the past year, many other communications of acknowledged merit, of which no mention has yet been made. To a few of them the council would now briefly advert, and especially to the last paper by Mr. Parkes, "On the action of Steam in the Cornish Single Pumping Engine," a communication of no ordinary importance and interest, either on account of its own intrinsic merits, as viewed in connexion with the past proceedings of this Institution, or the future pospects of this department of practical science. This communication, though intimately connected with those of the same author previously alluded to, growing immediately out of them, and depending upon the facts contained in them, is of a totally distinct character; being an attempt to explain, on theoretical principles, the action of the steam on the piston, and to unfold the real causes of the economy of the Cornish engines. This subject has occupied the attention of the Institution during the last four years, and the discussion first assumed a settled form during the session of 1837, on the receipt of the communication of Mr. George Holworthy Palmer, "On the application of Steam as a moving power, especially with reference to the reported duties of the Cornish and other Engines." In that paper the author, reasoning on certain data as to evaporation, and on the physical facts which involved the constancy of the sum of the latent and sensible heat in steam of all elasticities, and of the absorption of heat by matter on dilatation, came to the conclusion that no power could be gained by expansive working, and that, consequently, this could not be the *cause* of the economy in Cornish engines. This discussion was revived in the ensuing session by the communications of Mr. Wicksteed and Mr. Henwood, the former furnishing the first recorded experiment in which the water raised was actually weighed, the latter giving an extended series of most careful and detailed observations on the quantity of steam employed, the mode of its distribution, the duty performed by a given quantity of fuel, and the measurement of the water raised.

Taking for data the facts furnished by Mr. Henwood for the Wheal Towan, and by Mr. West for the Fowey Consols Engines, Mr. Parkes has analyzed the quantity of action obtainable from the quantity of water as steam consumed, and expanded to the extent used in those engines, and has found the steam's force unequal to the resistance overcome. After satisfying himself from various phenomena attendant on the working of these engines, that the amount of resistance opposed to the steam was not overrated, he was led to conclude that from the instantaneous and free communication effected between the cylinder and boiler of these engines, by the sudden opening of the large steam valves, a force must be transmitted to the piston, of a kind distinct from that of the steam's simple elasticity. This force he denominates the steam's *percussive action;* he adduces various proofs that this description of force has operated on the piston, and that it alone was equivalent, in the instance of the Fowey Consols Engine, to drive the piston through $\frac{47}{100}$ths of its stroke.

The author considers the effect produced on the piston of a Cornish Engine, by the sudden impact of highly elastic steam, to be similar to that obtained from water in the hydraulic ram. He has not in his paper entered on the consideration of the absolute amount of percussive force, which can be afforded by an aeriform fluid in motion—but has confined himself to the determination of the quantity of action, which he conceives to have been derived from that source in the particular engines examined. He invites the co-operation of others in instituting experiments on this subject, and the Council hope that the ensuing Session will augment the number of facts requisite for the complete demonstration and development of this view of the steam's action.

It is gratifying to reflect how much the present state of our knowledge is due to the discussions which have taken place at the meetings of the Institution. The Council look forward with great interest to the revival of these discussions, and for some valuable communications on this subject which are promised by Members who have daily opportunities of making observations and experiments on an extensive scale.

Among the other communications, the Council would briefly advert to that by Captain Basil Hall, on obtaining for Lighthouses all the advantages of a fixed light, by means of refracting lenses in revolution. It occurred to that distinguished officer that by placing a Fresnel lamp in the centre of an octagonal frame, having a lens inserted in every side, and causing the frame to revolve at a considerable velocity, a fixed or continuous light would be produced almost equal in brilliancy to the intermittent light from the same lamp when the frame revolved slowly.

Many curious effects are observed; thus, when the lenses are first set in motion the effect is a series of brilliant flashes; as the velocity increases, the light becomes more continuous—at about 44 revolutions per minute, absolute continuity is produced—and at 60 revolutions nearly the steadiness of a fixed light is attained. It would appear that the sensibility of the retina is affected by the succession of bright flashes, so that, judging by its intensity when seen through coloured glasses, the light would appear to suffer but little apparent diminution.

Another subject rather novel in its nature, but of considerable interest to the profession, on the "Application of Photography to the purposes of Engineering," was brought before the Institution, by your Member, Mr. Alexander Gordon. The facility with which this discovery may be applied to taking accurate views of buildings, works, or machinery at rest, renders it an object of great interest to Engineers; since by these means may be obtained the general dimensions of works, with perfect accuracy in a very small space of time, and by affixing a graduated scale to the objects to be copied, the photographic delineation would present the means of determining the dimensions of every part.

The Council cannot omit this opportunity of acknowledging the obligations which the Institution is under to Mr. Cooper and Mr. Cooper, Jun., who illustrated the preceding communication by exhibiting and explaining the apparatus requisite for the production of the delineations of photography.

The Council have to acknowledge the receipt of many valuable presents during the past year; and to record the liberality and zeal thus exhibited in the promotion of the interests of the Institution.

By the liberality of your President and of Mr. Burges, you are in possession of two portraits upon which every British Engineer must look with feelings of great pride and satisfaction. To the President you owe the beautiful portrait of Huddart, now suspended in your Meeting Room, and to Mr. Burges that of Smeaton, which adorns the walls of the Library.

The Institution has to acknowledge the continuation of the liberality of the Master-General of the Ordnance, of the Lord Lieutenant of Ireland, and of Colonel Colby, in transmitting the sets of Ordnance Maps as they are published.

The Council has also to acknowledge the receipt of some additional works from the library of the late Dr. Young, presented by his brother, Mr. Robert Young, whose liberality in making the Institution the depository of a large number of the works of that distinguished philosopher and benefactor to practical science, the Council of the preceding year had also to record in a similar manner. The Institution has also received a valuable set of Charts of the Coast of France, published under the direction of the French Government, from your President; a number of books from the Minister of Public Works at Brussels, collected by your Secretary during a recent visit to Holland and Belgium, when a communication was established between the Institution and the Ministry of Public Works of those countries; the Transactions of the Royal Institute of Naples from Colonel Cuciniello, through Mr. Albano; a valuable set of Crane Drawings from Mr. Leslie, and Drawings of the Carn Brae Stamping Engines from Mr. Sims, through Mr. Enys; some interesting models from Mr. Hick, a Pneumatic Mirror of his invention from Mr. Nasmyth, and a Radiating Stove Grate for the Library, from Mr. Sylvester; to these must be added the very numerous List contained in the Appendix to this Report.

The Institution has to regret the loss by death, of Mr. Francis Bramah, Mr. Oldham, Mr. Rowles, and Mr. Rickman; individuals distinguished for their attainments in professional and general knowledge, and endeared to the Institution by long association and deep attachment to its interests.

Francis Bramah was the second son of the late Mr. Joseph Bramah whose numerous inventions, perfection of workmanship, and genius in the mechanical arts, have rendered his name so widely and justly celebrated. The opportunities afforded to the son were ardently embraced by a mind of no ordinary powers, deeply imbued with the love of knowledge. Although his attention was in early youth more particularly directed to branches of minute mechanical construction, his acquaintance with the principal departments of professional knowledge and general science was very extensive. His attachment to the arts and to science was deep and sincere, and among many proofs of this may be particularly mentioned the valuable and essential services which he rendered to your late Honorary Member, Thomas Tredgold, both in his professional pursuits and in the prosecution and verification of his theories and calculations. Mr. Bramah being professionally engaged at Buckingham Palace, in connexion with some other engineers, difference in opinion existed and discussion arose, as to the true principle upon which the strength of cast-iron beams to resist stress and flexure ought to be estimated, and with the view of verifying the principles laid down by Tredgold, he instituted a very extended series of experiments, on the deflection and strength of cast iron beams. These he presented to the Institution, and they are published in the second volume of your Transactions.

Several important works were executed under his direction, among which the iron work of the Waterloo Gallery at Windsor Castle, the cranks, the lock-gates, and their requisite machinery, at the St. Katherine's Docks, and the massive gates at Constitution Hill and Buckingham Palace, may be particularly mentioned. Mr. Bramah was an early and deeply-attached member of this Institution; his constant attendance at the meetings, the information which he communicated, and his unwearied zeal as a member of the council, cannot be too highly estimated, and his loss will be deeply felt and regretted within these walls. The variety of his attainments, his refined taste in the arts, his amiable character and the warmth of his affections, had secured to him the respect and esteem of a most extensive circle of friends, by whom, as indeed by all in any way connected with him, his loss will be most deeply and sincerely felt.

John Oldham, the engineer of the Banks of England and Ireland, was born in Dublin, where he served an apprenticeship to the business of an engraver, which he practised for some time, but subsequently quitted to become a miniature painter, wherein he acquired some reputation. He pursued this branch of the arts for many years, but having a strong bias towards mechanical pursuits, he devoted much of his leisure time to the acquisition of that knowledge which was to prove the foundation of his future celebrity. In the year 1812 he proposed to the Bank of Ireland his system of mechanical numbering and dating the notes, and on this being accepted, he became the chief engraver and engineer to that establishment. The period of twenty-two years, during which he held this appointment, was marked by continually progressive steps of artistical and mechanical ingenuity. The various arrangements which he projected and carried out attracted great attention, and conferred considerable celebrity on the establishment with which he was connected.

The late Governor of the Bank of England, Mr. T. A. Curtis, had his attention directed to these important improvements, and under his influence the whole system of engraving and printing, as pursued in the Bank of Ireland, was introduced into the national establishment of this country, under the superintendence of its author, who continued in the service of the Bank until his death.

The ingenuity of Mr. Oldham was directed to other objects, especially to a system of ventilation, of which an account was given by the author during the session of 1837. Great versatility of inventive faculty, persevering industry, and social qualities of the highest order, were the prominent features in his character, and the success which attended his exertions is one of the many gratifying instances to be found in the history of this country, of talents and industry, destitute of patronage attaining to eminence in the professions to which they are devoted.

Henry Rowles, the chairman of the Rymney Iron Works, was educated in the office of his relative, Mr. H. Holland, the architect, on quitting which he entered into business as a builder. He was engaged, among other extensive undertakings, in building several of the East India Company's Warehouses, the Royal Mint, the Excise Office, and Drury Lane Theatre. He was an active Director in several docks, railway, and other companies, and finally became managing director of the Rymney Iron Works, in the active discharge of the duties of which office he continued until his death. The Institution owes to him the drawings of the iron works made by Mr. Richards.

John Rickman was educated at Lincoln College, Oxford, and graduated there; he subsequently devoted himself to literary pursuits, to political economy, and to practical mechanics. For some years he was conductor and principal contributor to the "Agricultural and Commercial Magazine." In 1801 he removed to Dublin, as Private Secretary to the Right Hon. Charles Abbot, then Keeper of his Majesty's Privy Seal in Ireland. Upon the election of Mr. Abbot to the Speaker's Chair in the House of Commons, Mr. Rickman continued to be his private secretary, and in 1814 he was appointed to the table of the House of Commons. He also acted as secretary to the two commissioners appointed by act of parliament in 1803, "for the making of roads and bridges in Scotland, and for the construction of the Caledonian Canal," and to the commissioners "for building Churches in the Highlands." The ability and energy which he displayed in the discharge and conduct of the duties of these laborious offices, for more than thirty years, in addition to his constant attendance at the House of Commons, called forth the warmest acknowledgments of public meetings held in the Scotch counties on his retirement, and various resolutions were passed expressive of the sense entertained of the unremitting exertions, and uniform and disinterested assiduity, with which he had promoted every object connected with the improvement and general prosperity of the Highlands and Isles of Scotland. The conduct of the affairs of the Highland Commissioners brought Mr. Rickman into constant intercourse with their engineer, Mr. Telford; an intimate friendship was formed between them, and Mr. Rickman completed and published the account of the life and works of that eminent man, which was but partially arranged at the time of his decease.

Mr. Rickman's chief work is the Census of Great Britain, in six folio volumes; he is also the author of numerous papers connected with statistics, having bestowed great pains in collecting and arranging the returns connected with education and local taxation. To this Institution he rendered very essential services, and whenever application was made to him in its behalf, was always zealous in endeavouring to promote its interests. The library was enriched by him with two copies of the Life and Works of Telford, and as the acting executor of Telford, he endeavoured to carry out, by every means in his power, the intentions of that great benefactor of the Institution.

Mr. Rickman's acquirements in every department of knowledge were accurate and extensive; to great quickness of perception, and memory of no ordinary power, were added indefatigable industry, undeviating method, and a sound critical judgment;—qualities which caused his acquaintance to be highly valued by the most distinguished literary characters of the day, and which, no less than the strict and scrupulous sense of justice and honour, which particularly showed itself in his considerate kindness towards all those with whom he was connected, will occasion his loss to be deeply regretted by a widely extended circle.

Address of the President.

Allow me to thank you for the compliment you have again paid me, by electing me your President for this current year.

The Secretary has reminded me, that I have been in the habit of addressing you on occasions corresponding with the present, but the very full, and I believe I may say, satisfactory Report of your late Council, has left but little for me to say on the business of the Institution. Your new Council have elected Mr. Manby for Secretary, Mr. Gibbon for Collector, and Mr. Hankey for Treasurer. We have the test of long experience in favour of the Collector and Treasurer, and although our acquaintance with your Secretary is shorter in point of time, we are all convinced that his whole attention and energies will be, as indeed they hitherto have been, devoted to the Institution.

Hitherto the increased number of our Members, and the attendance at the meetings during each year, have been commensurate with the growing importance of the Institution, and I have little doubt of the success of the present Session being still greater. We have under consideration several interesting subjects, to which some of our most active Members have paid great attention, and in which they have made important discoveries—these will form the ground-work of interesting and instructive conversation, or even, to use the language of a greater assembly, of 'debate,' but I trust that our discussions will continue to be conducted, as heretofore, with that good temper which makes even *debate* delightful, when the attainment of truth is the sole object. Truth will not bend one inch out of its right line, to accommodate false theory. He who tells us, that he "lost his patience when works were censured not as bad but as new," might be a very good poet, but in this respect at least he was no philosopher. One of our Vice-Presidents has presented me, within a few days, with a Report on the best mode of improving one of our great navigable rivers: this Report contains observations tending to level with the dust much that has been said by, I believe, all other Engineers, on the importance of tidal back-water. I know from experience that many theories which have, through their novelty or otherwise, appeared startling on the first view, have proved to be founded on truth, and have therefore superseded the old-fashioned notions. No class of men can be more devoted or bigoted to their opinions, than the Aristotelian philosophers were to their doctrine of syllogisms and *a priori* theories, which, though it had the authority of ages and names, was obliged to yield to the once-despised and even persecuted inductive philosophy of Bacon. Although, therefore, some Engineers may not coincide with the views expressed by our Vice-President, we shall do much good by examining impartially into the deductions he has drawn, at the same time carefully avoiding all personal considerations. A distinguished English Essayist after remarking that nothing denotes a great mind more than the abhorrence of envy and detraction, states, that the best poets of the same age have always lived on terms of the greatest friendship; and surely if this is the case with poets, who draw much upon imagination, Engineers, who have to deal with science and with facts, have less apology for excited feelings.

Without seeking in the recollections of a bygone generation for comparisons, we may congratulate ourselves that, although the number of Engineers has much increased, we are, I trust, without exception, *friends*: and I consider that our intimacy has been materially assisted by this Institution, where we have met, compared opinions, and rubbed off the sharp angles of professional jealousy or emulation, if any such existed.

Another valuable Member of the Council has, he conceives, discovered the true theory of the action of steam in the Cornish Single Pumping Engines, by which he accounts for their extraordinary economy. This theory, which is equally novel and ingenious, is now subjected to your examination and criticism, and I am sure that my friend Mr. Parkes would feel disappointed if his discovery were not to be submitted to that ordeal, in common with every similar subject of importance which is brought under the notice of the Institution.

While I congratulate the Institution on the increase of its Members, I ought at the same time to express my opinion, that from the number of young gentlemen who within the last ten years have studied for, or have entered, the profession, the supply is likely to be at the least equal to the demand; and to caution those who intend entering or are now studying for it, against confining themselves to the strictly professional part of the usual routine of education.

The Railways, both during the preliminary surveys and in their subsequent construction and management, in addition to other works of Engineering, have given employment to many. But the principal towns are already connected by Railways, or Engineers and Surveyors are now employed in projecting or executing lines where they are yet wanted. Is then the demand for professional gentlemen likely to *increase*? Is it not likely rather to *decrease*? Now certainly the number of Engineers or Students for Engineering is increasing. If we look at the number of students in the classes for Civil Engineering at the different Universities and Academies; the Universities of Edinburgh and of Durham; King's College, University College, and the College for Civil Engineers in London; we are led to ask, will this country find employment for all these? I freely confess that I doubt it. My object in what I have here said is, not to deter those who may already have resolved and have taken measures to follow the profession, but to advise them not to depend on this country alone, and so to direct their studies as to fit them for other countries also, where the field is not large enough to support men who are strictly and exclusively professional. For such, great countries only can find employment, and other great countries are educating their own engineers. To be fitted for going abroad to any part of the world, a man must be a tradesman as well as an engineer; he must furnish his *hands* as well as his *head*—and if he know more trades than one, so much the better; for he may have to direct in *all*, but *one* he ought to know thoroughly. Thus stored, all the world is open to him, and with the formation of new continents and colonies, and the improvement in the old ones, the engineer may insure independence. Not only in such countries, but at home also, his experience as a workman will prove his best friend and assistant in raising him to eminence, and make him feel that confidence in his own resources which has enabled so many engineers, whose name and fame stand high in the annals of the profession, to raise themselves from the millwright, stone-mason, and carpenter, to the highest grade. As a strong corroboration of the system which I recommend, you will observe the practical education given by each of these individuals to those of their family who are intended to succeed them. Let it not be supposed that I would undervalue the importance of science or of a scientific education, which is as essential to the Engineer as the knowledge of the principles of navigation is to the naval officer, but that I earnestly recommend *practice* also.

I hope to be excused this digression, but the great number of young gentlemen who, having been bred in Engineers' offices, apply to me for employment, which I cannot give them, or to be admitted as apprentices when I cannot in justice receive them, makes me feel very sensibly the importance of these remarks, and that it is almost a duty to give this publicity to my opinion.

To return to the Institution: I hope the attendance at the ordinary Meetings will be even better than that of last Session—that the Secretary's list which is regularly posted up, will have still a greater number of bright spots and a smaller number of black marks opposite the names of the Council, as well as of the Members, Graduates, and Associates generally. I do not name this as a complaint, for the attendance has hitherto gone on improving, that of the Council influencing the Members.

I have lately referred to the very great, and I fear, increasing, number of debts due to the Institution from Members and Associates, and still more from Graduates who were elected under a promise to send in an original communication or drawing, and I hope that the present Session will show a great reduction in the amount of these engagements. The fear of not producing something of sufficient value operates probably to overcome the desire which every gentleman, having made a promise, must feel in redeeming it. As an encouragement, let me refer such persons to the contributions by Graduates during the last Session; they will find that some of them required little inventive genius, but only the ability to record correctly what they have noticed on the public works in which they have been engaged, or which they have visited. To some of these, the Council have awarded premiums, and they esteem them valuable as recording details of works taken from measurements at the time of execution, thus forming an addition to our records, and making the Institution a deposit of "*works done*," which is one of its important uses; and I think no Engineer intrusted with public works would prevent Graduates having the opportunity of doing this for their own improvement, and for the benefit of the Institution.

The subjects for these papers, models, and drawings, are numerous,—I may almost say, innumerable. Of many of the great national manufactures of this country we have as yet no records in our possession, and until we possess them our stores will be imperfect. As an Encyclopædia gives a definition and general description of art, so should our Institution possess an original history, and drawings or models, as well as books, treating on every machine and manufacture connected with our profession.

Members of the Council during the last Session contributed liberally in books, and have set an example to the present Council. As a guide or specimen of the nature of the desired communications, the subjects for the Telford premiums have been varied and enlarged, but it is not to be understood that the subjects therein stated are to occupy exclusively the attention of Candidates, even for the Telford premiums. By thus enlarging the subjects and inviting papers, we may, I hope, look for an increased number of valuable communications, which it may press upon the Telford Fund to do justice to; I have therefore informed the Council that I have appropriated the interest of One Thousand Pounds, 3 per cent. Government securities, or Thirty Pounds per annum, which I request the Institution to accept, as my Annual Donation, to be applied as may appear best suited for the objects to which I have referred, or for other purposes conducive to the benefit of the Institution.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

March 8.—Jos. Kay, Esq., V.P., in the Chair.

Messrs. W. A. Burn, and J. J. Cole were elected as Associates.

The resolution of the Council was read on the Essay sent in for the prizes offered by the Institute, and it was announced that the medal had been awarded to Mr. Edward Hall, (late of Birmingham), for his Essay on Iron Roofs.

Mr. George Godwin called the attention of the Institute to the investigations in progress concerning the origin of several fires supposed to have been caused by overheating the pipes of hot water apparatus.—A discussion took place on the effects likely to be produced by the temperatures to which hot water may be raised under pressure, and Mr. Godwin was requested to ascertain and report to the Institute such facts as might be developed in the course of the inquiry to which he had alluded.

A paper was read on the Architectural Antiquities of Wisby, in the island of Gothland, communicated by John White, Esq.

Wisby in the 10th and 11th centuries was one of the most important commercial cities in the North of Europe, and is is said to have contained eighteen churches, of which there are still extensive remains. These buildings, which display the pointed arch, claim an antiquity greater than is generally conceded to that and other characteristics of the Gothic style, especially the church of St. Lawrence, built in the year 1046, St. Drotten in 1086, St. Peter in the same year, and St. Nicolas in 1097. These pretensions to the high antiquity of the pointed arch Mr. White supported by numerous citations from Klingvall, Pontanus, Jonas Coldingenses, and other northern historians. In the discussion which ensued, it was suggested that the original foundation of these buildings might have been preserved in history, and that they might have been rebuilt at a later period without any record of the fact having survived, an argument now fully admitted in several cases, (that of the Cathedral at Coutances for example), in which dates have been assigned inconsistent with the character of the architecture. But although Mr. White's paper may have been not altogether conclusive on this point, it drew forth the warmest acknowledgments of the meeting, as a most valuable accession of new matter to the stores of the architectural antiquary.

March 22.—Edwaro Blore, Esq., V.P., in the Chair.

Mr. Frederick John Francis was elected an Associate.

A letter was read from Professor Willis, Honorary Fellow, accompanying the copy of a curious and probably unique drawing (in England) of the profile of a door at Stephen's Church, Bristol, from a MS. of the Itinerary of William of Worcester, in the Library of Corpus Christi College, Cambridge. This work has furnished many of the technical terms used by the architects of the middle ages, but the drawing, which has been overlooked until the present time, throws new light upon several of them, especially on the term "corse," which has hitherto been a crux to antiquaries, and is omitted in some of our best glossaries.—Mr. Poynter first indicated the application of this word to the pinnacles of St. George's Chapel at Windsor, in the contract for vaulting the choir of that building, and its occurrence in the drawing in question applied to the flanking pinnacles of the doorway, seems to fix its meaning. It is probable however that the square shaft of the pinnacle only is intended, and that perhaps with reference to a peculiar use.—"A corse with an arch buttant" is mentioned elsewhere by William of Worcester, and in both the cases referred to, the shaft of the pinnacle serves as an abutment—at St. George's to the arch buttant (or flying buttress), and at St. Stephen's to the lofty pediment over the arch.

A paper was read on the Electrotype by Mr. G. H. Bachhoffner, Professor of Natural Philosophy, Queen's College, Guernsey, and Lecturer at the Royal Polytechnic Institution, who accompanied his experiments by several suggestions as to the mode in which practical architecture might be benefitted by this invention.

Mr. George Godwin in pursuance of the proceedings of the last meeting, detailed the results of the investigation into the cause of the fires at Manchester, conducted by Messrs. Davies and Ryder, at the instance of the Manchester Assurance Company, and embodied in their printed "Report on Perkins's system of warming buildings by hot water."—Mr. C. J. Richardson combated the report, and was disposed to question the accuracy both of the facts and conclusions. Even if it were admitted that ignition had been caused by hot water pipes, they were, according to his statement, not those of Perkin's apparatus, but of imperfect and bungling imitations.

The Institute then adjourned over the Easter holidays, the next meeting being appointed for the 19th of April.

THE OXFORD ARCHITECTURAL SOCIETY.

Feb. 10.—The Rev. Dr. Buckland in the Chair.

The following new members were admitted:—The Earl of Dunraven, Adare Mawr; Rev. the Warden of All Souls' College; Rev. Thomas Symons, M.A. Ensham; Rev. Henry Richards, M.A. Horfield, near Bristol; Thomas Stock Butterworth, Esq., Westbury, near Bristol; Rev. George Dawson, Exeter College; Rev. R. Greenall, Brasennose College.

The following papers were read:—

1. On Stanton St. John's Church, near Oxford, by Mr. Simpson, of Oriel College, illustrated by numerous sketches. The chancel of this Church is an interesting specimen of the transition from the early English to the Decorated styles towards the end of the thirteenth century. The east window is very remarkable and almost unique, the tracery being carried in straight lines through the head with foliations and good mouldings. Some of the original stained glass is preserved in the side windows, and some painting on the wood-work in the body of the Church.

2. On Montivilliers Church, in Normandy, by the Rev. T. W. Weare, Christ Church. This Church affords a curious specimen of the change from the Norman to the Gothic style, which was very scientifically traced by Mr. Weare, illustrated by several sketches, and by comparison with other buildings, particularly with Christ Church Cathedral.

3. On the restoration now in progress in the Temple Church, London, communicated by Sir Alexander Croke, through the President of Trinity College. This restoration appears to be conducted in the best taste, and is entitled to the cordial approbation and admiration of all lovers of architecture, and is the first real restoration of a Church to its original state, with its painted roof, stained glass windows, and polished marble pillars.

4. On the recent discovery, by the Rev. C. F. Watkins, at Brixworth Church, of the foundations of a round end to the chancel, from which it has been assumed that this was a Roman Basilica; and it is proposed by Mr. Watkins to rebuild the chancel in its original form and on the old foundations. The Chairman made some observations on the published account, and showed that the conclusion that this was a Roman Basilica was somewhat hastily arrived at, and scarcely borne out by the facts, since the round east end or apse was the common form of building Churches down to the twelfth century; and the workmanship of this Church is of so very debased a character as to be much more likely the rude imitation of a later age than genuine Roman work; nor does there appear to have been any occasion for a tower to a Basilica. It was also objected that to rebuild the chancel on the old foundations would perhaps invalidate the evidence, now so valuable, of its original form which these circular foundations afford. And a hope was expressed that measures might be taken to preserve these foundations in such a manner as to be accessible to the student of Architecture.

The Secretary mentioned that a local Society has been established at Bristol, according to a suggestion in the rules of the Oxford Society; and it was agreed that a copy of each of this Society's publications should be presented to the Bristol Society.

REVIEWS.

The Railways of England. By Francis Whishaw.

(Second Notice.)

Agreeably to the promise, we continue our extracts from Mr. Whishaw's work, the first which comes before us on this occasion relates to the Birmingham and Gloucester Railway.

The Ballasting on the London and Birmingham is thus described.

> The ballasting is of the width of 28 feet, and 22 inches in thickness. There are no less than seven different descriptions of ballasting; viz. burnt clay, burnt marl, gravel, sandstone, cinders, rock marl, and broken stone. The burnt clay and burnt marl cost from 1*s.* 2*d.* to 2*s.* 6*d.* per cubic yard; the gravel and sandstone from 6*d.* to 1*s.* 6*d.*; the cinders from 2*s.* 6*d* to 3*s.*; and the rock marl and broken stone (lias and oolite) from 9*d.* to 5*s.* 6*d.* per cubic yard. So many descriptions of ballasting, and so many different prices, cannot be heard of in the history of any other railway.

With regard to the Durham and Sunderland railway we find

> Some of the embankments on this railway are formed chiefly of small coal, which is, perhaps, the best material that can possibly be used for this purpose; the cost is stated to have been 9*d.* per cubic yard: except, however, in the largest coal distincts, its use is entirely precluded by the cost of carriage.

Of the inclines on the same line a longer account is given.

> To work this railway there are eight fixed engines: the first, or Sunderland engine, being of 70 horse power; the second, or Seaton Bank-top, 42 horse; the third, or Merton, 70 horse; the fourth, or Appleton, 83 horse; the fifth, or Hetton, 42 horse; the sixth, or Moorsley, 52 horse; the seventh, or Piddington, 85 horse; and the eighth, or Sherburn, also of 85 horse

power. Thus the united power is equal to that of 529 horses. The men employed in this department are nine engine-men, at 21s. a week each; twelve stokers, at 18s; and nine drummers, at 14s. each per week.

The first plane, ascending from Sunderland to Ryhope, is worked by three ropes; two being each 2450 fathoms in length, of $5\frac{3}{4}$ inches circumference, and weighing together 43,200 lb; and the third $4\frac{1}{4}$ inches circumference, and weighing 13,216 lb., and also 2450 fathoms long. The Seaton plane is worked by one $7\frac{1}{4}$ inch rope, 2,325 fathoms in length, and weighing 32,588 lb.; the rope is drawn out by the wagons descending by gravity. The Merton incline has two ropes; the one a 5 inch, 1250 fathoms in length, and weighing 8333 lb.; the other of $6\frac{3}{4}$ inches circumference, 575 fathoms in length, and weighing 6986 lb. The fourth plane is worked by one rope for the ascending, and by gravity for the descending wagons; this rope is of $6\frac{3}{4}$ inches circumference, 740 fathoms in length, and weighing 8990 lb. The fifth incline is also worked by one rope, which is of $4\frac{1}{2}$ inches circumference, 1425 fathoms in length, and weighs 7694 lb. The sixth plane has two ropes; the one being of the same length and weight as the last; and the other being 700 fathoms in length, $5\frac{1}{4}$ inches in circumference, and weighing 5121 lb. The seventh and eighth planes are each worked by a single rope, the length of each of which is 2450 fathoms; the size of the seventh being $5\frac{3}{4}$ inches, and the weight 21,600 lb.; and of the eighth, 4 inches, and the weight 15,120 lb. The whole weight of ropes, therefore, is 170,545 lb., or 76·13 tons. Mr. Blenkinsopp, the engineer of this railway, estimates the cost of these ropes at 40*l.* per ton, and their average duration about nine months. In this case, the annual cost for ropes on this line would be 2283·90*l.*, or 172·63*l.* per mile. At level road-crossings, the ropes run in channels properly constructed for the purpose. The rope-sheeves are of cast iron, weighing 28 lb. each, 12 inches in diameter and 7 inches wide; some of them being fixed in cast-iron standards, and others in wooden boxes, at intervals of 18 and 24 feet respectively. In curved portions of the line they are inclined to the horizon. At night the way is lighted by large fire-lamps, three at each bank-head.

The description of the inclines on the Dundee and Newtyle railway, will very appropriately follow.

The planes worked by fixed engines are the Law, the Balbeuchly, and the Hatton inclines.

The Law incline, which is 1060 yards long, the ratio of inclination being 1 in 10, is laid with three rails at top, four in the middle, and two at the bottom. It is worked by a forty-horse high-pressure engine, having a cylinder of $21\frac{1}{4}$ inches diameter; stroke 5 feet; rope-roll, 12 feet in diameter; the pinion on fly-wheel shaft having 32 cogs, and the spur-wheel on rope-roll shaft 97 cogs; the usual working pressure is 40 lb. on the square inch. The ordinary loads are from twenty to twenty-four tons, including a ballast-wagon of four tons, which always accompanies the train in its ascent, and is furnished with a break and clutches for the purpose of stopping the train in case of the rope breaking. The time occupied in the ascent is about six minutes. The counterbalance is of from ten to twelve tons weight. The cost of this engine is stated to have been 2750*l.* The rope is of $7\frac{1}{2}$ inches circumference, and weighs 8960 lb. The Balbeuchly incline, which has a single way only, is about 1700 yards in length, ascends at the rate of 1 in 25, and is worked by a 20 horse condensing engine; cylinder $26\frac{3}{4}$ inches, stroke 4 ft. 6 in., usual working pressure of steam $4\frac{1}{2}$ lb., the pinion on fly-wheel shaft has 48 cogs; rope-roll 12 feet diameter; and the spur-wheel on rope-roll 97 cogs. The usual load is about 16 tons; the time occupied in the ascent being six minutes. This engine cost 1600*l.* The rope is of $5\frac{1}{2}$ inches circumference, 900 fathoms in length, and weighs 7056 lb. The Hatton incline, which is also laid with a single way, descends to Newtyle, at the rate of 1 in 13, for a length of 1000 yards. It is worked by an engine similar to that for the Balbeuchly incline. The pinion, however, has only 31 cogs, and the spur-wheel 94 cogs. All the above inclines are straight; the sheeves are fixed at intervals of six yards. The consumption of fuel for the three engines is about 85 tons per month; the coals used are from Preston Grange, east of Edinburgh, and cost 10*s.* a ton delivered on the line.

The plan on the Edinburgh and Dalkeith railway, for stopping the trains in case of the rope breaking is ingenious.

Mr. Rankine calls it a self-acting stopper. It consists of two plates of iron, each having a double claw, the points of which are 15 inches asunder. These plates are each $13\frac{1}{2}$ inches in extreme length, 9 inches along the middle line of each, and 6 inches wide in the middle, increasing to 15 inches at the points of the double claw. The plates are $\frac{3}{4}$ of an inch thick, and $5\frac{1}{4}$ inches apart, secured together with $1\frac{3}{4}$ inches bolts. At the narrow end is a roller, 2 inches in diameter; in the middle is a 2 inch axle, to which an arm or lever is attached, this lever being connected at its upper end with the last wagon of the train. By means of the roller the stopper runs on one of the rails; and the lever, by which it is connected with the wagon, keeps the stopper at uniform distance from the train while in motion; but in case of the rope breaking, the train immediately runs back, raises the arm, and thus throws the stopper over, which causes the train to run off the rails.

On the subject of the Leeds and Selby earthworks, Mr. Whishaw approves of the mode of constructing the embankments.

Some of the embankments are of considerable height; and instead of being carried up with regular slopes, have their sides faced to a curved batter, the chord-line of which forms an angle with the base of about $67\frac{1}{2}°$. Where stone is plentiful, this is decidedly an economical mode of constructing embankments; for not only is the quantity of earthwork very much reduced, but there is also a considerable saving effected in the area of land required. The same observation will apply to the lower portions both of cuttings and embankments; for by carrying up retaining walls for about $1\frac{1}{2}$ to 2 yards in height, the quantity of excavation is much reduced, and also the area of land. Where stone-fence walls are placed on the top of the embankments, the whole width is 30 feet, and the clear width 27 feet.

We shall follow this by a description of the Manchester and Birmingham drains executed under the direction of Mr. Buck.

Besides the open field drains, circular perforated earthen drains are used to great extent in the cuttings. They are each 2 ft. 5 in. long, 14 inches in extreme diameter, and $12\frac{1}{2}$ inches in the clear. They are formed as iron water-pipes, with spigot and faucet; the clear diameter of the faucet, or larger end, being $14\frac{3}{4}$ inches, and the whole depth of the neck 4 inches.

The following observation is made by our author as to the use of bricks, while speaking of the Midland Counties railway.

The bridges almost throughout this line are built of red brick, the copings and strings being formed of hard-burnt brick earth, of the particular form required, as on the South-Eastern Railway. This plan might be advantageously carried out in many other districts where brick-earth is abundant.

Cowran Hill Cutting on the Newcastle and Carlisle railway hereafter described, was originally intended to have been a tunnel.

The strata intersected consist chiefly of clay, with intermixed veins of sand. The length is about one mile, the average depth 43 feet, and the greatest depth, 110 feet. The width of this cutting at level of rails is 26 feet. The sides are carried up with slopes of $1\frac{1}{2}$ to 1, and below the slopes is a retaining wall on either side, built of stone, 14 feet in height, 2 feet wide at top, and having a sufficient batter from the railway. On the top of each retaining wall is an open drain, which receives the water from the slope; and by means of vertical drains, which are connected with the main drains running under, and having the same inclination as the railway, the surface-water is entirely emptied into How Beck.

On the same line we have some interesting details as to the bridges.

There are several bridges of wood spanning the rivers. The chief one is that at Scotswood Road, being constructed on the skew principle. It is 30 feet on the square, and 50 feet on the skew span, and 30 feet high above the road. It is built of iron and stone, having five girders, weighing together 70 tons. The parapets are of rubble walling, coped with masonry. The whole presents a useful and economical piece of workmanship.

On the branch to Redheugh there is a bridge of singular construction, which carries a coal-way over the line. This bridge, which is of wood, and 3 ft. 4 in. wide, represents, as it were, the skeleton of lock-gates, consisting of four trussed portions, each hung folding, the meeting parts being furnished with small wheels, which run on iron segments when the gates are opened for the purpose of allowing the locomotives to pass.

Buchanan's Practical Essays on Mill Work and other Machinery. Re-edited by George Rennie, C.E., F.R.S., &c. Part I., 30 Plates and Text. London: Weale, 1841.

Robert Buchanan's Essays on Millwork are well known to every practical engineer, and still better as having been subsequently revised by Tredgold. To bring the progress of the art up to the present day, and to describe the modern improvements was a task yet to be attempted. This has happily devolved upon George Rennie, and it is almost superfluous for us to say that no better man could have been intrusted with them, to one who has cultivated with equal success both the theory and the practice, who is himself the author and inventor of so many of the innovations, which he will be called upon to describe.—Having contributed so much to enlarge the world of science, it was the least that we could expect of him, that he should come forward to do justice to his own works and those of his predecessors, the more particularly as he has in his own factory a museum from which to draw ample means of illustration.

The present Part is principally confined to the elementary matter, but the plates in it which refer to the forthcoming one give promise of most valuable matter. Among them are Bramah's Slide Lathe, his Lathe for turning Spheres, the Great Boring Lathe, the Wallside Drilling Machine, the Double Pillar Drill, the Key Grooving or Slotting Machine, Self-acting Nut-cutting Machine, machine for cutting the Teeth of Wheels, another for cutting the Teeth of Wood on Wheel Models, the Vertical Boring Machine for Cylinders, Planing Machine for Iron, Nasmyth's Planing Machine, a Punching Machine, Heck's Mandrel for expanding rings, &c.

Of Mr. Weale's exertions in this work we shall only say that both to civil and practical engineering he seems determined to afford equal benefit, those who remember Tredgold on the Steam Engine, will be prepared for a work got up with equal care.

The Laws of Trade. By Charles Ellet, C.E. Published in America. London: Wiley and Putman.

Some time ago we made long extracts from this author, explaining his system of charging tolls for goods; the work is now published in a collected form, and comes before us for recommendation to our readers. Mr. Ellet has exhibited great industry and acuteness in the investigation of a branch, as he says, but too little cultivated by engineers. The engineer who is best versed in the technicalities of his profession, will still be unadapted to the application of them, and the due discharge of his duties, unless he should have studied something else. The engineer is no bricklayer to put down a railway or canal just where he may be told, but he is an adviser who has equally to consult his own reputation in the stability of his works, and in the happy position of them for traffic. Mr. Ellet has conferred a boon on his profession, in calling attention to the laws which regulate traffic, and the revenue to be derived from it, and we hope that he will be imitated by his brethren here.

Tables of the Logarithms of Numbers, &c. By Edward Riddle, F.R.A.S., Master of the Mathematical School, Greenwich Hospital. London: Baldwin, 1841.

This is a cheap reprint of logarithmic tables from Mr. Riddle's work on Navigation, and as such we recommend it to our readers.

Practical Rules for the Management of a Locomotive Engine. By Charles Hutton Gregory, C.E. London: Weale, 1841.

Mr. Gregory is known as the Resident Engineer on the London and Croydon Railway, and some months ago he sent to the Institution of Civil Engineers a paper on the management of the locomotive engine, which since, by their permission, has been republished. It is made up in the form of a small manual, so as to go in the waistcoat pocket of an engine driver, and is printed in a good legible type. We equally applaud the design of the work and its execution.

An Experimental Inquiry into the Strength and other Properties of Anthracite Cast Iron. By William Fairbairn.

This pamphlet contains the continuation of Mr. Fairbairn's experiments on iron, and we refer our readers to it as containing some of the most valuable information as to anthracite, and the iron made from it.

ENGINEERING WORKS.

THE ARTESIAN BORING AT PARIS.

M. Arago who both as a member of the municipality of Paris, and as a "savant," has been one of the most active promoters of the Artesian Well of Grenelle, reported to the Academie des Sciences on the 1st ultimo, several details respecting the successful results obtained on the Friday preceding, which we think will be read with interest. Several Artesian wells on the right bank on the Seine at Epinay, Saint Denis and Saint Ouen, had given rise to the expectation of a supply to the city of Paris by the same means, which up to that time had been found attended with but a slight expense. The Municipal Council partaking in these hopes gave orders for the sinking of borings in the square of the Madeleine, at Gros Caillou, and at the Jardin des Plantes. The former was however abandoned nearly as soon as commenced, for reasons of a private nature, and the other did not succeed; nevertheless at the Jardin des Plantes the water had risen to within a few feet of the surface of the ground, essentially constituting an Artesian spring, although it held out no advantages beyond those of a common well, as in order to raise the water to the requisite height it was still necessary to have recourse to a pump. The fact of its not attaining a higher level at first appeared remarkable, but it was soon discovered that the sheet of water which fed the fountains of Saint Ouen and Saint Denis *cropped out* or came to the light on the banks of the Seine between Chaillot and Saint Cloud.—It was thus shown that this subterranean reservoir was subjected to a comparatively small pressure, and could give no encouragement to the establishment of Artesian foundations on the left bank of the Seine.

Notwithstanding this, the municipality entertaining views in accordance with those of a majority of geologists, did not give up the prospect of furnishing Paris with a supply of subterranean water. Already aware that several Artesian borings had been attended with immense success both at Tours and at Elbœuf, these being sunk into a stratum separated by the entire chalk formation from that of Saint Ouen, the council resolved in the year 1832 to make efforts to attain this second water-bearing stratum, and M. Mulot who had already undertaken several of the Artesian wells in the neighbourhood of Paris, entered into a contract to execute the Puits de Grenelle, which was commenced in the beginning of 1833.

Very nearly from the commencement of the undertaking unfavourable prospects became manifest. After perforating the tertiary sands, which at Grenelle are 41½ metres (136 feet) thick, and nearly as soon as the rods had reached the chalk, part of the rods detached themselves and fell to the bottom of the bore-pipe with great force. Considerable difficulties had consequently to be overcome, but these were soon surmounted, and the only result of this accident was a slight delay. In May 1837, when the boring had attained a depth of 380 metres (1246 feet 8 inches), a second and far more serious accident occurred—the chisel with which the ground was perforated, and a length of 80 metres (262 feet) of rods, again fell to the bottom. These weighed together (100 quintaux) five tons, a mass which it was absolutely necessary to raise again to the surface. It is already a serious matter to lift so considerable a weight when all the usual mechanical means are allowed to be brought into play, it may therefore readily be conceived that acting at a height above the object equal to thrice that of the towers of Notre Dame, and in a space having only a limit of a few inches, the obstacles are incalculable, and success almost a miracle. However, M. Mulot attained his object, he succeeded in tapping a screw on the head of the rods, and thus connecting another length to them, after 15 months of vain efforts, the chisel was at length brought up in August 1838, and the works proceeded with—they were, however, destined to be again interrupted before their conclusion.

The third accident occurred on the 8th April, 1840, the boring had then attained the rock chalk. Although the instruments were used with considerable dexterity, they made but slow progress. Suddenly however the chisel, the perforating end of which was extremely sharp, having been raised with great force, sunk at one stroke 26 metres (85 feet 3 inches) in the chalk. It then stuck so fast that no efforts could succeed in raising it, and had much force been resorted to, a fracture would have been the consequence, which would have led to a far more serious accident.—M. Mulot, whose inventive powers set a resolute face against every new difficulty, preferred setting the boring apparatus free by enlarging the hole on all sides, in which he was completely successful. The fourth accident was of less importance than the previous two, the chisel alone became detached, and its fall presented a new obstacle. M. Mulot at once saw that the remedy resorted to in the case which had occurred in May 1837 was no longer applicable, and the small size of the instrument led him to hope that he could pass on one side of the chisel. A cavity was formed in the side of the boring, and the instrument was forced therein. The works were then immediately recommenced, and no other detention occurred.

At last on Friday, 26th February, after 8½ years exertion, the rods suddenly sunk several metres,—the workmen perceived that all resistance had ceased, and after a few hours interval a majestic column of water 1691 feet in height (1847 English feet), the weight of which is equal to 53 atmospheres, rose from the bosom of the earth. Our globe having a temperature which increases as we descend, the water that flows from its interior assumes a warmth proportionate to the depth whence it rises. That of the Puits de Grenelle is at present 27°. 6 Cent. (81°.7 Fahr.) and it will increase as soon as the sides of the boring shall have attained the temperature of the ascending water.

The difficulties which have been described are not the only ones which this gigantic undertaking has had to overcome. The sides of the bore-hole are apt to crumble away, in which event the fragments falling in would fill up the hole and obstruct the working of the boring tackle. The strata which are perforated are also full of fissures, which might offer a vent to the ascending waters and cause them to be lost. These circumstances in connection with others which we cannot here enumerate, render it necessary to line the Artesian wells with a metal or wooden tube. This operation, which is not an easy one, even when a well is but some hundred yards in depth, increases in difficulty the deeper the works are carried. To effect it a tube of a certain diameter is first introduced, then a second one fitting into it succeeds, a third descends through the second, and so on;—these tubes exactly resembling those of a telescope. it is readily conceived that as they constantly diminish in diameter, unless they have been very nicely calculated, the aperture at last becomes too small for the free working of the boring rods. It is then necessary to lift all the tubes out and replace them by others of a larger diameter. At Grenelle it became five times necessary to remove the whole lining of the boring, and also each time to enlarge the bore-hole to allow of the introduction of larger tubes.—Let our readers then figure to themselves a cast iron column eight times as high as the towers of Notre Dame, which must be lifted out and replaced by another—they will then form a just conception of the patience, care and intelligence necessary.

The supply of water produced by the Puits de Grenelle is equal to upwards of four millions litres (880,387 gallons) per 24 hours, being nearly a gallon for each individual in Paris.—The waterworks of Gros Caillou Chaillot and the engine near the bridge of Notre Dame supply at the most, double this quantity: the well at Grenelle consequently, notwithstanding its first cost of 250,000 francs (£10,000), affords a cheap supply of water, more particularly if we bear in mind that this kind of fountain requires no repair.

Some persons are already raising doubts as to the continuity of the supply, resting their argument on the fact of some of the wells at Tours yielding less water at present than when first opened. They may, however, lay aside all uneasiness—if some of the wells at Tours have undergone a diminution, a greater number have increased in abundance, their supply having augmented by nearly one-third—and this discrepancy as it appears at first sight, is easily accounted for, by those who enter into all the facts of the case, being found to depend upon the more or less perfect lining of the borings. In the Province of Artois where Artesian wells which have existed upwards of 300 years are found, no diminution of the quantity of water produced has ever been observed—which by the way is quite natural, the sheet of water which supplies these having an almost unlimited extent—stretching as it does over a space of several hundred square leagues (1 square league = 5 square miles), the outlets to which (being these bore-holes) are almost unappreciable. This also shows us that greater numbers of wells may be sunk into the same stratum without affecting one another in the least. The outlay is however too great ever to lead us to expect much competition, and the perforation of the strata under Paris leaves us easy as to the future.

From an analysis made by M. Pelouze the water of the Puits de Grenelle is of a very good quality, and far purer than that of the Seine or of Arcueil, 100 litres only gave 14 grammes of extraneous matter (100 cubical inches gave $3\frac{1}{2}$ grains,) whilst a similar quantity of water from Arcueil, or from the Seine, yielded 17 grammes in suspension, and 46 in chemical combination, (100 cubical inches yielded 4·3 grs. troy mechanically suspended, and 11·6 grs. troy of chemical impurities).

An important question, and one the solution of which will not be completely attained for a few months, is the height to which the water will rise—referring to the levels where this water first percolates into the strata, we may hope that it will reach higher than the "Plateau" of the Pantheon—if this expectation be realized, all the various districts of Paris can be attained, and the improvements which the municipal council of Paris have long contemplated of supplying every habitation will be effected in a simple and economical manner, as it will only be necessary to make two or three other wells like that of Grenelle.

We cannot however be certain of the ascentional power of the water until the boring rods are withdrawn from the well, and the lining completed—some time is therefore still necessary before we know all the advantages which the perseverance of the municipality will have procured—a courageous perseverance which we cannot sufficiently praise, and which has had to encounter the lively attacks of many persons who fancied it impossible, that flowing water could ever be obtained by the means brought into play. The council however placed the greatest confidence in M. M. Eymery and Marie, the engineers charged by the "Ponts and Chaussées," with the superintendance of the supply of water to Paris, and who had first originated the proposal of an Artesian fountain —It was also supported by the opinions of MM. Elie de Beaumont and Arago, who never for a moment doubted of the final success of the undertaking, their confidence being based on analogy, and on a complete acquaintance with the geological conformation of the Paris basin.

We will endeavour to explain the reasons upon which they grounded their opinion :—

Paris occupies the centre of a basin, bounded on the west by the hills of Brittany and of La Vendée, on the south by the range which traverses the centre of France, and on the east by the Chain of the Vosges; this basin is filled up by successive layers, moulded as it were upon it, and fitting one into the other like those sets of cups we sometimes see inclosed in each other in order to occupy less room.

It will be clearly seen that each of these layers exposes its edges or outcrop to the day at greater or less distances from the centre. Those filling up the basin of Paris form three successive kinds of strata. The first or upper one called the tertiary formation consists of gravels and sands as found at Fontainebleau, of the gypsum which yields the plaster of Montmartre and St. Chaumond (plaster of Paris), of the limestone of Vaugirard and Montrouge, which supplies building materials for Paris, and lastly, of the plastic clay employed in all the potteries of the capital.—This last layer contains the sheet of water of St. Denis and St. Ouen. The second formation which immediately follows is the chalk which may be seen on the banks of the Seine from near Paris to Havre.

The third consists of various limestones connected with the Jura mountains, and consequently called the Jura formation (in England the oolitic).—The second water bearing stratum that of Tours and Elbeuf occupies the lower part of the chalk: it consists of a thick bed of sand inclosed in two very considerable layers of clay. The sand forms a kind of sponge which imbibes the water, and the beds of clay are as it were the sides of a pipe confining it, and whence it escapes whenever a perforation occurs. This stratum then, if it be continuous under the basin of Paris, if it exactly represent the cups we have described, must crop out at a certain distance from Paris, and form a kind of circle round it more or less regular in shape. This is actually the case. M. Elie de Beaumont has presented to the Academy a collection of samples of the sands belonging to this bed, and obtained at Cap la Hève near Havre, in the neighbourhood of la Fleche and Bonne Etable in the Sarthe, from Chateau la Valière in the Department of Indre et Loire, and from Allichamps near Vassy in the Haute Marne. All these are identical, and resemble the sand brought up with the water of the Puits de Grenelle. It is then evident to every one, as it long has been to geologists, that this sand forms a continuous basis to the Paris basin. Similar in shape to the bottom of a boat its sides rise to the day, whilst the centre is at a great depth from the surface. The waters falling on its edges or outcrop filter in and have formed a subterranean sea, occupying the entire width of the basin. Geology is thus established by the Puits de Grenelle as a positive science in the eyes of the whole world, and the conformation of the Paris basin made known with certainty.—*Le Constitutionnel, March* 4.

THE MAPLIN LIGHTHOUSE.

In the second volume of the Journal, page 38, we gave a description of the foundations of a Lighthouse to be constructed on a novel principal, by direction of the Trinity Board, under the superintendance of Messrs. Walker and Burges, the eminent engineers; the spot selected was the Southerly point of the Maplin Sands, which form the northern extremity of the Swin Channel, at the entrance of the river Thames. The foundations, as we before described, consisted of nine of Mitchell's patent mooring screws, with shafts of wrought iron 5 inches in diameter and 26 feet long, one was fixed in the sands in the centre, and the remaining 8 at the angles of an octagon 40 feet diameter, the screws were turned into the sand to the depth of 21 ft. 6 in., the top being then within 4 feet of the low water mark of a spring tide.

After the screws were fixed in August 1838, it was determined to leave them for a few months; from that period to June 1839, every change in the surface of the sand was observed, and notwithstanding that in the early part of 1839, there were several storms of more than ordinary violence, yet the screw piles stood firmly, and the sand at no time was lowered more than 3 feet. As a precautionary measure the engineers had constructed an open platform or raft of timber in two thicknesses, crossing each other at right angles, and bolted together at their intersections, which covered the whole site within the piles, and also extended some distance beyond them; round the exterior was raised a curb 18 inches high; over the platform was laid brushwood, and then about 200 tons of rough stone which sunk the raft on to the sand and prevented it being displaced, between the spaces of the platform and the brushwood the sand was allowed to work its way up, which soon filled the interstices of the stone. Very shortly after the whole of the platform and stone was embedded below the surface of the sand, which gave considerable support sideways to the screw piles, and formed a solid body for the water to wash upon. Nothing farther was done on the spot till the framing for the construction of the lighthouse was ready to be fixed in August 1840, when upon a careful examination it was found that the raft had completely settled down, and the piles as firm as the first day they were screwed in—it was then determined to proceed with the erection of the superstructure, which we shall now proceed to describe. The lower part consists of eight cast iron pillars 18 feet long, 11 inches diameter externally, and 9 internally, they are fixed at the angles of the octagon, and in the centre there is a similar pillar 22 feet long; the lower part of the pillars forms a socket, and is fitted over the top of the shafts of the screw piles to the extent of 4 feet, to which they are attached by adjusting screws of wrought iron; the upper part of the pillars also forms a socket 12 inches clear diameter, and 4 feet deep, into which are fixed the principal posts of the timber framing—these pillars are fixed inclining towards the centre. The pillars are tied together at top and bottom with wrought iron horizontal bars $2\frac{1}{4}$ inches diameter, fitted with collars and screw bolts; similar bars are fixed on the same level in a raking position to the centre pillar, by the aid of which the whole are firmly tied and braced together—the top of the pillars stands about 4 feet above high water mark of a spring tide. The timber framing was commenced by first fixing the centre post 21 feet long and 14 inches square, and subsequently those of the angles, 30 feet long, 12 inches square at the base, and 10 inches square at the top; they are tied together at the bottom by double horizontal tie beams, 12 by 5, and 27 feet long, and at the top 10 by 4, and 21 feet long; the ends are secured to the angle posts by wrought iron nut and screw bolts and iron knees. There are also raking braces from the angle posts to the centre $10\frac{1}{2}$ by 9, and 15 feet long; upon the tie beams are laid the flooring joists 9 by 3, the principal posts of the carcase framing are 6 by 4.

The interior accommodation consists of a living room 22 feet long, and a store-room in the upper part, and store-rooms for coals and water in the lower part. Thus far the erection was completed in October 1840, within a period of three months.

Above the living-room is fixed the lantern with a gallery all round—it is a polygon of 16 sides, 12 feet diameter internally, and 16 feet high from the floor to the roof; the principal part of the framing is of cast iron—the roof, the interior lining and floor are covered with copper. In the centre, raised upon a pedestal, is the beautiful apparatus of a second order of Dioptric light, made and fitted up, together with the iron work of the lantern, by Messrs. Wilkins and Son, of Long Acre. The height of the light above the mean level of the sea is 45 feet, and may be clearly seen from the deck of a vessel, in fine weather, upwards of 10 miles off in all directions. The light was first exhibited on the evening of the 10th of February last.

PLYMOUTH BREAKWATER LIGHTHOUSE.

A lighthouse is in course of erection upon the western extremity of the Breakwater, the first stone of which was laid by Admiral Warren, on the 22nd of February last, it was designed by Messrs. Walker and Burges, the engineers of the Trinity Board, in July last, and submitted to the Admiralty. Shortly after, their Lordships gave directions for its immediate construction. It is to be erected upon an inverted arch, the foundation of which is laid about 1 foot 6 inches below the level of low water spring tides, its centre at top is at the distance of 37 feet 6 inches from the western end or head of the Breakwater, and at the level of low water 195 feet. The diameter of the head of the Breakwater at the level of low water is 390 feet, and at the level of the top of the Breakwater 75 feet. The lighthouse is to be of granite 14 feet clear diameter, the centre of the light will be 55 feet from the top of the Breakwater. The interior will be divided into floors, forming a store room, a dwelling-room, a bed-room, and a watch-room. The lantern 12 feet wide and 7 feet 6 inches high, is to show a Dioptric fixed light of the second order, with mirrors; the south half to show a red light, to distinguish it from the coast lights, and the north side towards the Sound, is to be white. The stones of the lower courses are to be secured with dowels of slate, independent of a vertical and horizontal dovetail, the dowels are 18 inches long and 6 inches square at the centre, and sunk 8 inches into the lower course of stone, both ends are dovetailed and secured in their places by plugs in the upper, and by wedges in the lower stone. It is expected that the lighthouse will be completed by the end of 1842.

MERSEY AND IRWELL NAVIGATION.

We present in the accompanying reports of Mr. Palmer and Mr. Bateman the groundwork of a long discussion,* which has taken place at the Royal Victoria Gallery, Manchester. In this discussion which lasted for several evenings, Mr. Hawkshaw, Mr. G. W. Buck, Mr. Joseph Radford, Mr. W. Fairbairn, Mr. T. Fairbairn, Mr. Bateman, Mr. Thomas Hopkins, and other engineers took part. The proceedings are of particular interest on account of the important questions concerned in them, and of the public being thus brought to take a part in a professional subject. Of a debate of such length it would be impossible to give even an abstract, but we may mention some of the opinions put forward. Mr. Palmer is in favour of contracting the upper part of the river estuary, and forming the river as a funnel; Mr. Bateman is in favour of contracting the upper part, but opposed to interfering with the estuary; Captain Denham, opposed to contracting the estuary; Mr. W. Fairbairn, on Mr. Bateman's side; Mr. Buck, in favour of contracting the upper part, thinks the estuary might be partially contracted; Mr. Hawkshaw, of opinion that the upper part could not be improved without the neck of the estuary below Liverpool being contracted; Mr. Radford, Mr. T. Fairbairn, and Mr. Hopkins support Mr. Palmer. Thus in favour of improving the upper part of the river, the numbers are—

For, 7 .... Against, 1

With regard to the bay at Runcorn Gap,

For Mr. Palmer, 4; Mr. Bateman, 2; against, 2.

With regard to contracting the Mersey,

For, 4...... Partially, 1...... Against, 4.

Extracts from a "*Report on the Improvement of the Rivers Mersey and Irwell between Liverpool and Manchester, describing the means of adapting them for the navigation of Sea-going Vessels. By Henry R. Palmer, F. R. S., Vice-Pres. Inst. C. E.*"

At the time when inland navigation by means of artificial canals met with such extraordinary encouragement, the prevailing opinion was opposed to the use of rivers, chiefly on account of their currents, especially during rainy seasons. Probably this impression may have derived some of its strength, from the well-known bold expression attributed to the late Mr. Brindley, under whose superintendence the Bridgewater Canal was constructed. The advantages which that celebrated work exhibited over the natural line of navigation, *at the time* the former was constructed, were no doubt obvious, and many other instances might be cited, which would equally point out the superiority of an entirely artificial canal, over an *imperfect* or *ill-regulated* line of river navigation.

The actual distance, in a straight line, between the quay at Manchester, and the Company's Dock at Liverpool, is about thirty-three miles; while the length of the channel, in its natural course, between the same points, is forty-eight miles; the circuities amounting to no less than fifteen miles. Those circuities have, however, been reduced seven miles, leaving the present length of the line of navigation forty-one miles.

The width of the river at Manchester is 108 feet, at Warrington 140 feet, at Fidler's Ferry 170 feet, and at Cuerdly Point 650 feet.

From thence it rapidly widens to 3,500 feet. It is abruptly reduced to 1,200 feet at Runcorn Gap, and, within a short distance, is again widened to 4,200 feet.

* It was our original intention to have published the discussion, but it extended to such a great length that we were obliged to abandon our intentions. —Ed.

The widths continue to vary considerably towards the river's mouth, extending in one part to two and a half miles, and again diminishing to 3,300 feet at Liverpool.

The level of the highest tide, uninfluenced by a strong wind, intersects the bed of the river at Woolston, being a distance by the course of the channel of about 25¾ miles above Liverpool, and the bed of the river at Manchester is 49 feet above the level referred to. The first weir in the ascending direction is at Warrington, and the distance from thence to Manchester is divided into 10 pools.

The navigation of the river between Liverpool and the lock at Warrington is dependant upon the tidal water, and the whole of the remaining distance upon that derived from the uplands.

At Liverpool the spring tides rise	33 feet
At Runcorn	16½ „
At Warrington..................................	8 „

The lowest of the neap tides at Liverpool rise 23½ feet, and if the wind be strong in the adverse direction they do not extend to Runcorn. The depth of water at Liverpool with a high spring tide is 89 feet, but the bed of the river is rapidly elevated, and the depth during the same tide is diminished to 33 feet in a distance of 9½ miles.

A 33 feet tide at Liverpool occasions a 16½ feet tide at Runcorn; thus showing the bed of the river at Runcorn to be about 16½ feet above the level of low water mark at sea, assuming the line of high water mark to be level between the two places. This, however, is not strictly the fact, and will be hereafter the subject of explanation.

The river is subject to considerable land floods, which descend with great impetuosity, and overflow the banks, laying under water extensive areas of marshes. A land flood implies an accumulation of the water of drainage derived from a more than ordinary quantity of rain. The river channel being proportioned only to an average quantity, the surface of the stream is necessarily raised. But the accumulations that are so injurious, and which are complained of, are not to be attributed to any natural deficiency in the capacity of the channel, but to the permanent barriers or weirs that have been erected, which diminish the water space nearly three fourths, without any compensation having been provided.

The evil consequences of such circumstances are of far greater magnitude than has been supposed. It is well known that the water in its descent over the lands, washes down such loose soil as it is capable of removing; the same being conducted into the channel of the river, it is carried out to sea, if the moving power continue to be sufficient throughout the whole distance. The natural slope of the Mersey above the tideway is such as would occasion a considerable velocity of the water, but by dividing it into a series of pools, the velocity is, as it were, concentrated at the weirs, and the motion between them is much inferior to that which is required for removing the soil brought down by the rains. The cleansing of the channel is therefore exclusively dependant upon extraordinary quantities of rain from whence an increased velocity is obtained.

But if the weirs were altogether removed, it is obvious the river above the tideway would cease to be navigable: weirs of some kind are indispensable where the slope of a river is great, but it is equally clear, that they should be so constructed as to prevent the least hindrance to the motion of the floods.

Seeing that the fixed weirs contribute so largely and injuriously to impede the motion of the water, and therefore to elevate its height during floods, we find that a large proportion of it is made to pass over surfaces which are in no way benefitted, but which are damaged by it; while its use as a scouring power is altogether lost. While these effects cannot, perhaps, be entirely prevented, they may be greatly diminished, by so constructing the weirs that the impediment they cause shall have relation to the quantity of water in the river. If the weirs were properly made self-adjustable, according to circumstances, the bed of the river would be acted upon during longer periods, and therefore more effectually cleansed.

From the parallelism of the upper division, its bed is comparatively regular. The lower division is, however, of a contrary character; the extent of surface covered by the tides is such as to permit an effect upon their motion caused by the winds. The sands of which the bed is composed are therefore subject to a change of place, and hence the positions of the shoals are ever liable to variation.

From this circumstance the channel or line of deepest water varies also, and becomes divided in various places; so that instead of one permanent course, having a depth which is due to the natural force of the descending waters, several channels are formed, of which neither can be of the depth, that in a single channel, would be maintained.

There can be no doubt that the condition of a river is best for the purposes of navigation, when the deepest part is limited to one permanent and regular track. This can be effectually obtained only by causing the flowing and ebbing waters to act in the same lines; such a condition may not be practicable where the scale of the river is of so great a magnitude, that the motion and action of the water is influenced by winds.

The *principle*, however, should be kept in view, and should be approached as nearly as the means extend. A regularity in the outline or borders of the river is essential for the production of the effect required; and while the opposite banks of the Mersey remain as they now are, totally inconsistent with each other, we cannot hope for the improvement so much needed, and which is obviously within the power of art greatly to assist.

But to obtain that degree of regularity or parallelism which is required, certain excrescences in the area must be enclosed, by which it will become reduced. It is to the consequences of such a measure that the numerous opinions before adverted to were directed, and which have now to be considered.

It has been asserted that the open broad areas of the river at a considerable distance above Liverpool, are necessary for the maintenance of deep water towards the river's mouth; and it is thence inferred that if the area of the river towards the extremity of the tideway were diminished, great injury would be sustained towards the outfall.

The shoals are said to accumulate, and the depth of the channel diminish; and a great proportion of such effects have been attributed to the enclosures that have been made from the river in the upper part of the tideway.

In order to investigate the subject in question fairly, it is indispensable that the *source from whence the accumulations are derived be ascertained*, (*i. e.*) it must be known whether the materials which constitute the accumulations for the most part are derived from the sea shore, os whether they are brought down by the rains from the surface of the uplands?

That matter is brought from the interior and carried towards the sea, is a fact too well known to require more than allusion to it. But that the quantity so brought down and deposited in the bed of the river is scarcely perceptible, and that it does not produce any sensible injury, may, I think, be demonstrated in a satisfactory manner. It must then follow, that the accumulations complained of are *supplied from the sea*. I have confidence in being enabled to prove *that the great expanses in the area of the upper part of the river, are not only not beneficial to the outfall, but that they are injurious to it.*

If the accumulations were derived from the uplands in any sensible degree, the quantities deposited from time to time might be expected to bear some proportion to the quantities of rain fallen at different periods, because the quantity of matter brought down and conveyed through the upper division of the river to the tideway, must be regulated by the quantity of water which conveys it. But it is a fact long ascertained and known beyond doubt, that the accumulation of the sands in the vicinity of Runcorn (above and below that place) *is greatest when there is least water descending from the uplands.* Such is the amount of accumulation in *one dry season*, that it is felt by those who navigate the upper part of the tideway. It is then to be observed, that the accumulations progressively increase until the arrival of a land flood, on which occasion the excess that had become deposited is removed. The fact therefore is, that the quantities of accumulations in the river are inversely in proportion to the quantities of rain; and hence there is less deposit upon the bed of the river in the tideway when the greatest quantity of silt is brought down from the uplands. From this reasoning we may infer, that if there were no descending land stream, and if the whole area of tideway were a *mere bay*, the same would gradually silt up, and become dry land. Such would be the fact, and it will be shown that however extensive the receptacles for the mere tidal waters, they do not contribute to the preservation of the outfall.

The cleansing of the outfall is admitted by all to be dependant upon the force of the *outward* motion of the water. It must therefore follow, that the *inward* motion of the same (*i. e.* the flowing tides) will act in a similar manner, and bring with them such quantities of sand as they are capable of moving. The question then refers to the comparison of the *inward* with the *outward* forces. If the force of the ebbing tide do not exceed that of the flowing tide, it is evident that no greater quantity of sand can be carried out by the former than that which is brought in by the latter. If the ebbing water have an excess of power over that which flows, it is certain that a greater quantity of sand will be carried out than is brought in, and consequently *the depth must gradually increase*. But such, however, is not the fact, *although the ebbing tides are assisted by the waters from the uplands.*

From what has now been stated, I trust it will appear manifest, that the *effect* of the flowing tides in raising the bed of the river, exceeds that of the ebbing tides, and hence we may conclude, that *the depth of the channel is entirely and exclusively dependant upon the water derived from the uplands.*

Although I cannot imagine a doubt upon the fact just mentioned, the subject is of so much importance, that I must beg permission to make use of another argument.

If the deposits in the tideway were derived from the uplands, we surely ought to detect the fact by reference to the substance of which they are composed. I have obtained specimens of the bed of the river from various parts of it, and have found that the substance in the higher part of the tideway corresponds with that taken from below Liverpool. I have also found that the loose matter in the bed of the river above the tideway, has a different character. It is true that the strata of the district through which the river passes from its source is silicious, and, therefore, the debris partakes of that character; but in form it differs, and, as may be supposed, is mixed with various other substances, of which coal dust and soot may be taken as prominent ingredients. Now, the difference in colour of the general mass of specimens taken from the higher part of the river, especially that near Manchester, and that of the specimens taken from the neighbourhood of Runcorn and Liverpool, is such, that no doubt remains of their being derived from different sources.

Considering the character of the district through which the river passes, the immense consumption of coal on both its banks, and the prodigious quantity of loose coloured matter that must necessarily be washed into its stream, I certainly did expect to find some appearance of such matter in the sands in the vicinity of Liverpool, but although I employed a very high magnifying power, no such particles could be detected.

We have also abundance of examples, which prove most obviously, that with tidal rivers the raising of their beds is produced by the flowing tides, while the products of the land waters are *not observable until the tides have elevated the surface to nearly the height to which they rise.* The dimensions of the particles, a descending stream is capable of carrying, depends upon the velocity with which the water moves, and that velocity is determined by the slope of the bed. Most rivers appear to be progressively diminishing in depth, and hence we may safely infer, that their depths towards their outfalls were greater in proportion to the remoteness of the periods; their slopes must therefore have been greater, and the masses brought down proportionally so, and the debris derived from the uplands and deposited in the rivers must increase in dimension in proportion to the depth at which is is found. Although the common velocity of a river may be insufficient for the removal of gross particles, (say coarse sand,) it may be sufficient for carrying matter of a lighter description, and it is probable that all such light matter as arrives in the tideway of the Mersey, during the ebb-tide, is actually carried out to sea; but such as may arrive during the flood-tide, which at high water does not happen to be deposited on those parts of the bed over which a current passes when the tide returns, will *remain where it falls*. Now this can only happen where the sands have accumulated to a considerable height from another source before described, and it seems that the deposits from the uplands in the process now going on in the Mersey, are for the most part of the lightest description, and they are to be found only under the circumstances mentioned. All this reasoning is sufficiently supported by an examination of the soil of which the upper portion of the marsh land is composed, and may therefore be safely relied on.

The coasts of Surry, Kent, Suffolk, and a portion of Norfolk, are bordered by beaches of shingle, which are kept in perpetual motion by the action of the sea, and the component parts are continually seeking a place of shelter, and hence they enter and accumulate about the mouths of all inlets which have not the advantage of an opposing force, derived from a never-failing stream from the uplands. The direction of their prevailing course is determined by that of the most frequent or prevailing action of the waves, or breakers of the sea, and although a land stream be sufficiently powerful to maintain a passage to the ocean, yet such is the action upon the loose substances which compose the shingle, that their motion cannot be prevented, and the outfalls of the rivers become diverted into a direction parallel with the shore, unless such an effect be opposed by artificial means.

If, then, notwithstanding the existence of the constant aid of a land stream, it be difficult to retain an unencumbered outfall, much less can it be expected that a clear opening shall be preserved where such assistance is not available.

Leaving the operations of nature entirely free from control, it does appear that all inlets upon a coast invested by a shingle beach, and which are not preserved by the discharge of a stream from the land, must gradually diminish. The accumulating process is abundantly exhibited on the coasts alluded to. Dover, Folkestone, Rye, and Shoreham, afford excellent instruction upon the subject.

Nothing is more common than to assign, as the cause of decay in harbours, the enclosure of spaces which previously received the tidal waters, while the ordinary processes of nature are totally unheeded. I have never yet heard any reasoning which explains in what manner the abstraction of the tidal space can or does produce the effects complained of. If the flowing and ebbing forces be equal, the latter can only remove from a harbour the same quantity of matter the former may have deposited.

But upon careful examination of all the actions contained in the process, it will be seen that the flowing forces are the greatest, and hence we need seek no further for causes that produce the effects which we observe and lament.

But an approach to parallelism in the banks, is useful in another way: the tapering form of the opposite sides is known to contribute to the advancement of the tides towards the extreme points of their access. *The spring tides at Runcorn do now rise to a higher level than the high water mark of the same at Liverpool, while some neap tides, if opposed by the wind, will not reach that place.* In the latter case the tides at Liverpool return before the whole estuary has been filled, which would not occur if the area were to be diminished to its best proportion, and the sides properly regulated.

Very remarkable and interesting evidence on this branch of the subject is to be found in the Severn and Wye. The channel of the Severn is *funnel-shaped*, and the height to which the water rises increases with the distance reached; thus—

At Swansea a spring tide rises	30	feet
At the mouth of the Avon ..	40	„
At the New Passage........	50	„
At the mouth of the Wye ..	60	„
At Chepstow...............	70	„

Some portions of the rise at Cheptow may, however, be ascribed to the quantity of water descending from the mountains. These facts I have personally ascertained.

Now although the Mersey is of a different form from the Severn, yet it may readily be conceived that the momentum of this great body of water in the river below Runcorn, must, where the space is suddenly contracted, as it is at Runcorn Gap, cause a swell, and it therefore flows to a greater perpendicular height at Runcorn Docks than its natural level at Liverpool. This effect has, as before stated, been limited to spring tides, the neaps being contrary.

Mr. Bateman's Report to the Company of Proprietors of the Mersey and Irwell Navigation.

Gentlemen—In my recent investigation at Runcorn, as to the best means of improving the navigation there, I was led to the consideration of the general improvement of the river Mersey, and particularly of that part which lies between Runcorn and Warrington. A mode of effecting this in a manner which appeared to me likely to be beneficial to every party interested, suggested itself; and, in the belief that it is deserving your attention and consideration, I take the liberty of laying it before you.

The improvement of the river for navigable purposes is a subject of great importance to the proprietors of the navigation—to the town of Warrington, and to all who can participate in the advantages which may be expected to result. It is a subject which has frequently excited the most serious attention, and it appears recently to have been taken up with a spirit from which some practical and useful result may be confidently expected.

The river possesses within itself the means of very great improvement; and I am convinced, that, if these resources were sufficiently investigated and developed, no great length of time would elapse before we should see vessels of three or four times the present burden, unloading their cargoes at the quays of Manchester.

It is becoming of daily increasing importance, when we consider the vast impetus which must be given to the trade of Manchester and its neighbourhood, by the many important railroads which are now constructing—the great increase in the carriage of merchandise which may consequently be expected—the important benefits which the Inland Bonding Bill, if suffered to pass into a law, will confer upon the town, and the probable increase in the carriage from that cause also—with the necessity of carrying the facilities of inland navigation to the highest pitch of perfection, in order to cope with the powerful rivalry of callateral railroads.

The river, as far as the navigation extends, may be considered as naturally divided into three parts; from Liverpool to Runcorn; from Runcorn to Warrington; and from Warrington to Manchester.

The first is a wide and open estuary or inlet from the sea, navigable at high water of all tides, for vessels of considerable burden; and being from its nature susceptible of little improvement beyond the deepening and straightening of the channels. At high water, it is for the most part from two to three miles in width; but, at low water, the channel is generally not more than 200 or 300 yards. Upon this portion of the river, steamers ply regularly at every tide, between Liverpool and the various canals which enter the river near the town of Runcorn, for the conveyance of goods and passengers, and for tugging vessels; and it forms the utmost extent to which the natural navigation of the river, assisted by the tides, can be regularly and certainly made.

The second division forms the upper end of the estuary, separated from the lower part by a narrow strait called Runcorn Gap, where the opposite rocky shores approach to within about 400 yards of each other, projecting considerably within the limits of high water, both above and below. It is nearly a mile wide at the lower end, and terminates upwards in the ordinary channel of the river, which is probably about a hundred yards in width. It is only navigable at high water of spring tides, for vessels of more than 40 or 50 tons burden, and has been found so beset with inconveniences and difficulties, that the navigation of it has been nearly abandoned, artificial canals having been constructed inland, for the purpose of carrying on the communication.

The third portion lies above the reach and influence of the tides, and is strictly an artificial river navigation, having been rendered available for that purpose by locks and weirs, to the town of Manchester, and shortened and straightened in various parts by artificial cuts. It is only now, however, capable of being used by vessels ordinarily about 40 or 50 tons burden, drawing about four feet of water. The depths of the pools vary considerably, being in many cases 10 or 11 feet, and in others not more than four or five feet.

The navigation of this part is capable of being greatly improved, and may be adapted at a reasonable expense to the conveyance of vessels of 150 tons burden, or probably more.

Several bridges would prevent the passage of high-masted vessels; but all steamers, and such vessels as could sufficiently lower their masts, might make the entire navigation. This is perhaps now of less importance than it would formerly have appeared, as, from the rapid progress steam navigation has recently made, we may reasonably expect a very large proportion of the trade will be carried on by that means; while, to a considerable extent also, vessels expressly adapted to the circumstances of the navigation, would no doubt be constructed. A survey for the purpose of reporting the most effectual means of accomplishing the improvement of this part of the river is now in progress, and I have little doubt the report will be of a very satisfactory nature.

The main difficulty in the way of a general improvement to the town of Manchester, so as to take vessels of the size above mentioned, appears to exist in the inconvenient state of the navigation between Runcorn and Warrington; and it is to the improvement of that portion of the river that my attention has been particularly drawn, and to which I shall confine my observations.

Whether any definite plan for the improvement of this part, or the removal of its natural difficulties, has ever been proposed, I am not aware; but from the opposition with which all attempts to carry bridges over the estuary at or above Runcorn Gap have been met with, and from the jealousy with which any encroachment on the tideway has been watched, the general impression seems to have been that it was necessary to keep it in its present state,—that of an open unobstructed tidal river.

I rather think here has been generally a kind of vague idea, that some important plan of improvement would sometime or other be projected, and an apprehension that any alteration in the river might tend to prevent the accomplishment of the anticipated scheme; and, therefore, all parties have been particularly anxious to keep it in its natural and original state.

The examination I have made of the river with information obtained respecting it, and a careful consideration of all the circumstances connected with it—have led me, however, to the conclusion that so long as the river above Runcorn remains an open estuary, washed over by the tide, it will be impossible to effect (except at an enormous expense) any advantageous or permanent improvement.

The main difficulties under which this part of the navigations labours, are want of sufficient depth of water to carry vessels of any size up to Warrington, except during high spring tides—the short period of time during which it can even then be done—the circuitous and ever-changing channels—and the constant alterations of the sandbanks which are operated on and shifted both by tides and land floods.

To remove these difficulties—to secure a constant and unchanging channel of sufficient depth to allow nearly all vessels to go up to Warrington at any state of the tide, that can reach Runcorn Gap—to give a longer period of time during which the navigation can be made—to do away with the danger and annoyance of being neaped on sand banks, as at present—and to do all at a reasonable and warrantable expense, and so as not to injure the navigation of the port of Liverpool, nor injuriously to affect any other interest, is the end to be desired, and the end which, I hope to be able to show, the plan I have to suggest will be sufficient to attain.

I have mentioned, that the width of the river at Runcorn Gap is about 400 yards, and it is bounded at each side by precipitous rocks. The tides here, even when pressed by strong winds, never rise more than 20 or 21 feet; and at low water the greatest portion of the channel is dry, there being little more than a few feet of water in any part.

The plan I have to propose is to throw an embankment across the river at this place, with proper and sufficient locks and flood gates to admit and discharge the tidal waters under certain regulations.

Were the question merely confined to the best means of improving the navigation from Runcorn upwards, without reference to any effect to be produced below, a simple embankment or weir, with self-acting flood-gates to admit and impound the high tide water, with such locks as might be necessary for the navigation, would be all that would be required; for by that means you would have a pool constantly filled, deep enough to float vessels to and from Warrington, at every hour of the day, drawing 12 or 14 feet of water.

But it becomes a question as to how far the obstruction to the flow of so much tidal water, with its scouring effect upon the channel during ebb tide, would affect the entrance to the port of Liverpool, or the navigation from Liverpool to Runcorn; and I am of opinion, that, unless measures were adopted to prevent it, an embankment only, which would constantly keep up the water, would have an injurious tendency.

To prevent this, and for the purpose of always maintaining a deep channel (and I believe in a more effectual manner than can now be done), I would propose the construction of sufficiently capacious flood-gates to discharge at half-ebb of spring tides, when the most effectual scour is going on, the whole body of water which is impounded, refilling the pool at the next tide.

Having thus stated generally the nature of the plan, I will proceed to explain it more in detail, to point out what I consider its advantages, and to investigate the objections which, it appears to me, may be urged against it.

The average height of the tides at Liverpool over the old dock sill, is about 15 feet,—the highest being about 21 feet, and the lowest 10 feet. These measured from low water are respectively about 33 feet and 23 feet.

An 18 feet tide at Liverpool, being an average spring tide, and about 30 feet in the river, will rise about 15 feet at Runcorn, and 8 feet at Bank Quay, near Warrington.

Such a tide will allow vessels drawing 13 feet to reach Runcorn, and such as draw 8 feet, about 100 tons burden, to go forwards to Bank Quay. A neap tide will scarcely bring a vessel drawing 8 feet to Runcorn, and it will carry nothing at all (but a flat, perhaps) to Warrington.

The average of vessels drawing the greatest depth of water which reach Runcorn, may probably be taken at 10 feet, varying from 100 to 200 tons burden; and this size includes nearly all the coasters, those engaged in the Irish provision trade, and steamers.

At present, such vessels can only get forward to Warrington, at the very highest spring tides, perhaps two or three times in the course of the year; but, by the plan suggested, they will be able to do so as often as they can reach Runcorn; and, when once at Warrington, all steamers, and such vessels as can lower their masts, may go on to Manchester, when the necessary improvements on that portion of the river are effected.

It seems that the difference in the depth of water between Runcorn and Bank Quay at high tide, is about 7 feet. Of this I am inclined to think 4 or 5 feet is attributable to the natural declivity of the ground, and the remaining 2 or 3 feet to the fall in the surface of the flood tide, which, I apprehend, never attains the same relative height at Bank Quay as at Runcorn. If I am right in this conjecture, the effect of an embankment will be as follows:—

A tide rising 15 feet at Runcorn will (as I have shown before) give, as the river is at present, 8 feet of water at high tide at Bank Quay; but, supposing this tide to be retained at Runcorn, and prevented from flowing back, the water would gradually level itself, by rising at Bank Quay, and falling at Runcorn; and if the width of the river were the same from one end to the other, and the difference to begin with was 3 feet, it would rise 1 foot 6 inches at Bank Quay, making the depth of water there 9 feet 6 inches, and fall the same amount, 1 foot 6 inches at Runcorn, reducing that depth to 13 feet 6 inches. As the river, however, is much wider at the lower than the upper end, the fall at Runcorn would be less than half the amount of the difference, and the rise at Bank Quay more than half,—making the depth there probably 10 feet. Suppose further, that the land or river water was allowed to flow into the pool, so as to raise the entire surface to the level of the original tide, 15 feet at Runcorn, which would occupy about a day and half, there would be a depth of 11 feet at Bank Quay; and, supposing the river is then allowed to flow on through the pool as usual, we must add the fall or declivity in the surface necessary to give it the requisite velocity;—this would be about 2 or 3 inches in a mile, and the distance being, say 7 miles, we should have an additional depth of from 1 foot 2 inches to 1 foot 9 inches to add, making the total depth at Bank Quay from 12 to 13 feet, being a gain of from 4 to 5 feet depth of water.

As this depth is 2 or 3 feet more than is required to float a vessel of 10 feet draught, it will be sufficient if we retain a tide rising 12 or 13 feet at Runcorn, or 15 or 16 feet over the old dock sill at Liverpool. It is of importance to mark this, as you will perceive by observations I shall have to make upon the scouring power I propose to substitute.

Laying aside for the present any consideration of the effect which may be produced below Runcorn, I can see no objection which can reasonably be urged against it, but the possibility of the river gradually silting up, by the deposition of material brought down by floods. The mode I have to suggest of scouring out the channel, will, I think, almost entirely remove the possibility of this being the case, in the navigable channel; but, even without that, I do not think it would have such an effect. The river would maintain its course and current along the deep, depositing whatever it might bring down on the sandbanks and shallows at each side, where there would be little or no current, thereby gradually raising and preparing for agriculture purposes, an unprofitable waste of sands, washed over now by every high tide by which they are frequently removed and carried into the deeps.

I know many instances of rivers maintaining a distinct course through large lakes; but two, which must be familiar to nearly everybody, will be sufficient to mention. The Rhone through the Lake of Geneva, a distance of 37 miles, and the river Bann, for 18 miles through Lough Neagh, in Ireland; each river maintaining a deep and distinct channel through the entire length of lake. The Rhone, however, and, I have no doubt, the Bann also, forms a delta on first entering the lake.

I think that, generally, the channel would be improved; and if deposit was to take place in the upper part of the estuary, where the river would first enter into comparatively still water, it might easily be removed by dredging.

The benefits to the town of Warrington, in particular, must be too obvious to need any remark. The Sankey Canal would obtain a much better entrance than it has now; and the Mersey and Irwell Company would have so much of their navigation permanently improved, and rendered available for a large class of vessels, which they may then take on to Manchester.

We now come to consider the effect which may be produced upon the channel below Runcorn Gap, and upon the entrance to the port of Liverpool.

It would be of little use to suggest plans for the improvement of the upper part of a river, if the mouth were to become so choked up that no vessels could enter; and, in the maintenance of a good entrance to the port of Liverpool, the Mersey and Irwell Canal Company is as vitally interested as any other party can be.

I hope to be able to show, that, so far from the suggested works being likely to do injury, they will assist in scouring out and deepening the channels all the way out to sea.

Much evidence was given, in the trial betwixt the Old Quay Company and the corporation of Liverpool, in 1827, relative to the scour of the river; and from that it appears, that the most effectual in cleansing and deepening the channels is that produced by the ebb tide, when about half down, and the land floods: the latter losing much of their power, however, in the lower part of the estuary.

As this accords strictly with my own observation, and the information of those connected with the river and daily navigating it, I have no hesitation in taking it as the fact.

It appears, then, that the early part of the ebb tide is of little service in improving the navigable channels of the river; and indeed this must be obvious, when it is considered that the water is then running with pretty nearly equal velocity over the whole bed of the river, and removing probably more sand from the banks into the channels than it carries out of them.

Now, if any considerable portion of the water that is thus wasted, as it were, could be retained until the tide was half down, and then set at liberty, it would have the effect of keeping up the river for some hours longer at the most effectual scouring point, and be thus enabled to work deeper into the channels, and carry the sand or silt removed further out to sea.

I think I can make it clear, that this will be the result of the scheme proposed during spring tides; and that, during neap tides, or whenever prevented from flowing beyond the gap, the water will rise higher at Runcorn than it can now, and consequently increase the velocity of the ebb. In either case there will be a strong tendency to improve the channels both above and below Liverpool. The estuary will contain, to begin with, nearly if not quite as much tidal water as it does now, and under regulations which will render it of more effectual service, while eventually the improvement of the deeps will enlarge its capacity.

The upper part of the estuary and river, from Runcorn Gap to Howley Weir, at Warrington, containing at high water of spring tide (including Halton Marsh) about 1,300 acres, is about 1-17th of the entire area of the estuary above Rock Perch. In spring tides, at high water, it contains from 1-25th to 1-30th, and in neap tides from 1-40th to 1-50th of the whole body of water.

Mr. Giles, in his evidence for the corporation at Lancaster in the suit before referred to, calculates the contents of the river at ordinary spring tides, from Runcorn to Warrington Bridge, at 10 1-3 million tons, or about 13,733,000 cubic yards. As a 15 feet tide at Runcorn falls 8 feet to half ebb, considerably more than half the quantity has flowed out before that time, so that the remainder, say six million cubic yards, is the only portion that is effectually employed in scouring the deep. As this is six hours in ebbing out, the velocity becomes so trifling towards the end as to be ineffectual.

In neap tides the effect is proportionably less.

The late Mr. Nimmo, in his evidence for the company in the same cause, gives from actual measurement the ordinary flow of the river above Warrington, and the depth of a very heavy flood over Woolston weir, from which I have been able to ascertain its volume.

From Mr. Nimmo's observations, the fair average of the ordinary quantity may be taken at 40,000 cubic feet, or 1,480 cubic yards per minute.

The flood appears to have been about 580,320 cubic feet, or 21,493 1-3 cubic yards per minute, or nearly one million and a half yards in a hour,—probably nearly equal to the tide at half ebb. It was running at the rate of 113 yards in a minute, or nearly four miles an hour.

It is half ebb at Runcorn rather earlier than at Liverpool; and from half ebb to the commencement of the flood tide at Liverpool, there is about three hours. It is during this period that I would propose to discharge the water which would be retained above our embankment.

I have stated, that a 15-feet tide at Runcorn has fallen eight feet, or to half ebb. If flood-gates were constructed in the bank, 60 yards in length, 8 feet in depth, and opened at half ebb so as to obtain an average pressure of 8 feet to the bottom of the discharge, the quantity discharged in the three hours would be nearly six million cubic yards, or about the whole quantity now contained in the estuary with a similar tide at half ebb, and requiring six hours to flow out.

If the discharge sluices occupied 100 yards in length instead of 60, being then 1-4th of the width of the gap, the discharge in the three hours would be more than nine millions and a half cubic yards, being half as much again as all the water now left in the estuary at half ebb, and more than 2-3rds of the whole contents measured at high water of spring tides, and nearly equal to the whole quantity at half ebb added to three hours of such a flood as Mr. Nimmo mentioned. The discharge would be at a velocity of 10 feet per second, or nearly seven miles an hour, and would, after mixing with the other water, maintain a velocity of three or four miles much greater than the mean velocity after half ebb at present.

There cannot be a doubt, I think, that, under such regulations, the scouring power would be greatly increased; and, while below the gap, the direct force of this power would be employed in deepening the channel and carrying out the sand and silt to sea, the velocity of the current above the gap would be so much increased and confined to a particular direction, that the channels there would also be deepened, and any casual deposit carried out; so that, independent of other improvements, the channels of the whole river would be improved from Warrington to the sea.

After these discharges the pool might be refilled at the next tide, or whenever the tide rose more than 13 feet at Runcorn. At the lowest spring tides, for three or four days together, and at the highest, for seven or eight days together, perhaps twice each day, but at any rate every alternate tide, much less frequently than this would, I am satisfied, be found amply sufficient.

The next point is, that, by the tides being prevented from flowing beyond Runcorn Gap, they would rise higher there, and, by thus attaining a greater head or elevation, which will be another advantage besides, would produce an increased velocity in the ebb.

The tide flows past Runcorn at the rate of five miles an hour; and if stopped there by an embankment, and prevented from flowing up to Warrington, and filling that part of the estuary, the momentum, which impels it forward for an hour after it has turned at Liverpool, would cause it to impound in front of the embankment. From calculations I have made, I am disposed to think that the additional rise would probably be about 1-20th of the total depth of water, or from four to nine inches, according to the height of the tide. This amount, small as it appears, would be of service in neap tides.

I have now, I think, gone over the main points which appear to me materially to bear upon the question; and I hope I have succeeded in explaining them in such a manner as to render them intelligible, and enable you to understand my views.

If I am any thing nearly right in the data I have taken, and the conclusions I have drawn from the calculations I have made, the advantages in every point of view must be considerable, nor are these advantages confined to the navigation only; the adjoining landowners may reclaim a large portion of the land above Runcorn, which is now covered at high tides; a good road, with draw or swivel bridges over the locks, may be formed on the top of the embankment, and thus join the two counties of Lancaster and Chester in a very much superior and more convenient manner than is now afforded by the dangerous and inconvenient ferry. Even a railway viaduct, if carried at a sufficient height, would then be no objection; and many miles of railway travelling might be saved to the London and Liverpool traffic, by crossing here, and joining the Grand Junction at Prestonbrook.

It only remains to explain shortly the kind of works which would be required.

The width of the strait at Runcorn Gap is about 1,250 feet. The bed of the river consists of about 35 feet of rock on the Cheshire side, dry at low water; about 715 feet of sand and silt in the middle of the river, extending, I believe, to a considerable depth partially dry at low water; and about 470 feet of rock, all above low water, on the Lancashire side. The rock extends inland on each side, rising considerably, particularly on the Cheshire side, above high water level.

I would propose to construct two sea locks *in* the rock on the Cheshire side; one 180 feet by 40 feet, and the other 120 feet by 30 feet, with hydraulic gates, so that they may be self-acting, and used for the purpose of scouring. In the rock on the Lancashire side, I would recommend the construction of the self-acting flood-gates, and between the limits of high and low water there is ample space for *ten*, with 30-feet clear water openings in each; the gates to be revolving on an upright axle, placed a little on one side of the centre, so that one leaf of the gate should be rather larger than the other. The gate, of course, must open only one way, the larger half turning *up* the river: when, therefore, the flood tide rises higher than the surface of the water on the upper side of the gates, the pressure being greater upon the larger leaf than the smaller, the gate opens, and the water is freely admitted. When the tide has reached its greatest height, and begins to fall, the pressure is then reversed, and the gates close, retaining all the water that has flowed past the embankment. To open the gate, and discharge the water *en masse*, various methods might be adopted. The simplest, perhaps, would be to draw up out of the larger leaf a paddle of sufficient size to make the smaller leaf expose a greater surface to the pressure of the water, when, of course, the gates would open by the down-stream pressure, as they would in the other case by the up-stream pressure. The paddles may be worked by self-acting balance weights, or by a water wheel set in motion by the fall of the tide, so as to make the whole self-acting. The water, after its discharge, may be directed by proper jetties into the channel required.

Over the intermediate space of sand and silt, betwixt rock and rock, I would propose an embankment composed of rock and earth in the manner shown in the drawing; the centre of the bank of puddled earth or clay; and the outer parts of rock faced with heavy squared pitching brought up from low water in a curved manner, as shown in the drawing. In order to secure as much as possible or necessary the water tightness of the bank, I would recommend a row of sheet piling perhaps 25 or 30 feet deep on each side of the puddle wall in the centre of the bank, and at the foot of each slope another row of shorter piles, to prevent the pressure of the bank forcing out or blowing up the sand foundation.

A carriage road to be formed over the whole, passing over the locks by draw or swivel bridges, and over the sluices by stone or wooden arches.

This plan, with 15 feet of water impounded, would afford a sectional area of discharge of 5,970 square feet. The calculations in my report are made upon an area of 2,400 square feet only, so that, if by that amount the scouring power was trebled, it would, by using all the means which the locks and sluices of the plan just detailed afford, be increased more than seven-fold.

At a ten feet tide at Runcorn, the sectional area of the stream is now about 9,860 square feet. The locks and sluices would afford at the same height about 4,120 square feet. Although this is less than half the present sectional area, a difference of level of considerably under a foot would so increase the velocity through the sluices as to pass the same quantity of water.

WARMING BUILDINGS BY HOT WATER.

The subject of warming buildings by hot water having lately excited a more than ordinary degree of interest, owing to the recent disastrous fire at Manchester, we lay before our readers a report made to the Manchester Fire Assurance Company, by Mr. John Davies, M. W. S., and Mr. G. V. Ryder. (We shall continue the subject in our next.)

"Before we proceed to detail the experiments which we have made, we shall briefly describe the appearances observed, and the information obtained at a few of the principal places which have been visited. We shall then be enabled not only to confirm but to extend the statements in Mr. Ryder's first report.

It has been found, on inspection, that Birch Chapel has, at various times since the occurrence alluded to in the former report, sustained much damage. Wood, matting and cushions have, in a variety of places contiguous to the hot water pipes, been charred to an alarming extent.

With respect to Mr. Barbour's warehouse, farther inquiry has fully corroborated the previous statements of its having been on fire, close to the pipes, at different times and in different places.

Of the Unitarian Chapel, in Strangeways, the directors are already in possession or information from both Mr. Ryder and Mr. Rawsthorne, and this information seems to leave no doubt as to the injury which has resulted from the use of Mr. Perkins' hot water apparatus.

The heat in the Natural History Museum having been repeatedly stated to vary in different parts of the pipes, and to become, in some cases, the greatest at places remote from the furnace, the fact has been confirmed by our own observations, and by our subsequent experiments. As this circumstance has excited much interest, and been generally questioned, we shall presently endeavour to assign the cause.

The apparatus, which it may be proper to notice in reference to its general form and construction, consists simply of a long, endless iron tube, carried, in different directions, from a furnace to which it returns, and in which about one-sixth of the whole length is inserted and formed into a coil, so as to be sufficiently exposed to the action of the fire. The tube is, at the commencement, filled, or nearly filled, with water, which, by the application of the heat, soon begins to circulate, and, in that way, to impart an increase of temperature to the apartments which it traverses. The dimensions of the pipes are such, that, on the average, eleven feet in length will contain one pint of water. Connected with the principal pipe are two others, which are opened by a screw, one to allow for the ultimate expansion, and both subservient to the introduction of water.

As far as lay in our power, we have made such experiments aa occurred to us, repeatedly, and under every variety of circumstance.

Not having any instruments which would furnish speedy and adequate criteria for the determination of high temperatures, we have resorted to the inflammation of combustible bodies, and the fusion of others, depending on the recent and high authority of Professor Graham for the degrees which they indicated.

The ordinary method hitherto resorted to for ascertaining high temperatures in the pipes, is to file a small portion perfectly smooth, and observe the progressive change of colour which occur. We did not neglect this experiment, and we witnessed, to great advantage, the successive and beautiful tints. As the temperature increased, we were presented first with a straw colour, then a deep bluish purple, and, finally, with a dark silvery hue. The first is said to indicate 450, and the blue 600.

In the Natural History Museum we applied our tests, but were enabled to do so only to a very limited and unsatisfactory extent. Mr. Walker, the proprietor of the patent right for Manchester and the neighbourhood, accompanied us to the establishment of Messrs. Vernon & Company, engravers, where we had the opportunity of trying the system rather better, but still imperfectly. Finally, Mr. Walker acceded to our request to have put up, on his own premises, a suitable apparatus, which was to be submitted entirely to our control. It consisted of an iron pipe upwards of 140 feet in length, 26 of which were coiled in the furnace; 20, at least, being freely exposed to the full action of the fire.

In addition to the apparatus, as at first fitted up, we had a branch pipe and a stop cock, which enabled us, by cutting off at pleasure a great portion of the circulation, to perform our experiments on a contracted scale, and under a variety of modifications.

Mr. Walker, being from home at the time, placed his foreman entirely under our directions, so that we had the opportunity of pursuing the investigation to any extent which we might think proper. It is but justice to state, that this person rendered, very willingly and with much practical skill, all the assistance which was required.

The apparatus having, on Friday the 5th ult., been fitted up and found on trial, to be in proper condition, the experiments were commenced on the following morning, at ten o'clock, when the apparatus had arrived at a suitable state.

I. *First class of experiments, viz. those made with the whole length.*

1. The pipe from the furnace became very soon sufficiently hot to singe and destroy small feathers resting upon it.
2. Speedily afterwards, the same pipe exploded gunpowder.
3. On the highest pipe, within a foot of the expansion pipe, bismuth was readily melted, denoting a temperature exceeding 470°. The pressure at this point must have exceeded 35 atmospheres, or above 525lb. on the square inch.
4. Feathers were singed instantly, and matches lighted, at the same place.
5. Gunpowder inflamed readily in various parts of the flow pipe, and on the expansion pipe.
6. Blocks of wood, of five different species, were charred: from the dea wood the turpentine issued profusely.
7. Other combustible materials were also severally much charred.

II. *Class of experiments, with the shorter circulation. By this change a greater pressure was immediately observable, as the expansion pipe and several of the joints emitted steam, and admitted the escape of water.*

1. Cane shavings, on the pipe above the furnace, readily inflamed.
2. Lead melted at the same place; and the temperature must, therefore, have exceeded 612°. Making a rough calculation from the table of the French Academy, which does not extend beyond 50 atmospheres, I take 612° to represent 75 atmospheres, or about 1,125lb pressure on the square inch.
3. Different wood shavings inflamed on the upper pipe.
4. Cotton ignited freely at the same place.
5. Matting inflamed at the same place.
6. Cotton, hemp, and flocculent matter, collected from Mr. Schwabe's fustian room, ignited on the returning vertical pipe.
7. The blocks of wood, tied to different parts of the tube, were much acted upon and charred in a very short time.

Observing the expansion pipe to be in a state of considerable agitation, and warned of an explosion, the temperature was reduced, and the experiments were, for the time, suspended.

The pipes having, before three o'clock, been refilled and screwed up, for the express purpose of an explosion, the following experiments were made in the progress of the preparation:—

1. Mungeet was readily ignited.
2. Different sorts of paper and pack thread were destroyed.
3. Bismuth fused instantly.
4. Cotton inflamed.
5. Sheep's wool became speedily charred, in 2″ or 3″ after the stop-cock closed.
6. At five o'clock the sheet lead, affixed to the upright pipe, freely melted; steam issued violently from the bend in one of the upper horizontal pipes, and, in three minutes afterwards, the explosion occurred in the furnace pipe, at the top of the seventh coil, which presented, on subsequent examination, a lateral aperture about two inches long and about one-sixteenth of an inch broad.

In the lapse of two or three minutes after the commencement of the explosion, the furnace was entirely emptied of its contents, which were propelled, in a divergent direction, like one mass of fire, so as almost to fill the apartment. The force with which the ignited embers rebounded from the opposite wall, and other obstructions, occasioned them to scatter in profusion like a shower of fire over every part of the place. The noise was so great as to bring to the spot a multitude of people from the adjoining streets. A number of articles in the shop—as, for example, packing cloth, paper, and hemp—were subsequently found to be on fire in different parts of the premises.

These appearances, and their immediate effects, seem to have been precisely similar to those which are said to have been witnessed at the explosion in the warehouse of Messrs. Crafts and Stell, and would evidently have been adequate, in the same situation, to produce all the consequences.

It may be here observed, that the experiments clearly prove, that the heat, in different parts of the pipe, is not uniform. Generally it is greatest at the highest elevation, where its superior temperature appears to be of the longest duration under ordinary incidental changes. At the commencement of the operation, however, and a short time after fresh fuel had been applied, the temperature was highest in the flow-pipe contiguous to the furnace. Another circumstance, likely to produce an inequality of heat, may be adverted to: the tubes are far from being of uniform internal diameter: the consequence of which must be, that as the same quantity of water has to pass, in the same time, through every part of the apparatus, the liquid must move with greater velocity at one place than at another, and thus, from obvious causes, develop a greater quantity of caloric. The difference is sometimes so great in the relative bores of the tubes employed, that in some which were examined, one tube had an internal diameter of 9-16ths, and another of ¾ths of an inch, that is to say, in the ratio of three to four; or, taking the relative areas or sections of the tubes, which represent the relative quantities of fluid contained in a given length, in the proportion of nine to sixteen. Thus, taking the velocity reciprocally as the section of the pipe, the velocity of the water at one part of the apparatus being represented by sixteen feet, the velocity in another part would be nine, or the rapidity of the current would be at one place nearly double that which it was at another.

It is stated, in a work recommending the hot water system, that "the application of heat fills" the ascending or flow-pipe "with minute bubbles of steam which rise rapidly to the upper part of the tube, and become there condensed into water again:" now, as condensed steam, wherever it occurs, produces about seven times as much heat as the same quantity of water at the same temperature, we have, at once, a reason for the heat of the pipe being generally greater at a distance from the furnace than contiguous to it. This apparent anomaly, which has been repeatedly observed and denied, admits, therefore, of an easy explanation.

The explosion may, under different circumstances, occur from various causes.

1. As water expands in bulk about five per cent. from 40°, its point of greatest density, to 212°, the boiling point, the expansion must be very considerably more when raised to high temperatures. If, therefore, the pipes be nearly filled with water, and the expansion pipe not adequate or in proper condition, an explosion must be inevitable. Dr. Graham states, that, from freezing to boiling water, the expansion is from 22.76 to 23·76 = 100 to 104·4 nearly.

2. The conversion of the water into vapour, producing an expansion which is in the proportion of a pint of water changed into 216 gallons of steam, "with a mechanical force sufficient to raise a weight of 37 tons a foot high," must present a pressure upon the tubes sufficient to ensure their destruction. Dr. Graham makes a cubic inch of water to expand into 1,694 cubic inches of steam, or one pint of water to become nearly 212 gallons.

3. It has been observed, as an ordinary occurrence, by those much accustomed to the apparatus, that, in some cases, a quantity of gas is generated, and has been found to escape, in considerable quantity, when an aperture is made in the upper part of the pipes. The only gases which could be thus obtained are the elements of the water, oxygen and hydrogen. The former would probably be taken up in the oxydation of the metal. Now the hydrogen gas, which would remain, has never been deprived of its elasticity, and never made to change its state, by any compressing force hitherto applied. It is obvious, therefore, that inevitable danger must arise from its production. It may be worth while to remark, that air, steam, and hydrogen gas expand in the same proportion by augmentations of temperature. The law discovered at the same time, and by independent methods of experiment, arose out of the researches of Dr. Dalton and M. Gay Lussac. It may be thus expressed: Aeriform bodies expand the 1-480th part of their bulk on the addition of each degree of temperature. Thus, taking 480 cubic inches of steam or hydrogen gas at 32°, the mass becomes, at 33°, 481 cubic inches; at 34°, 482, cubic inches; and so on: or, in a general form, a bulk a raised $d°$ of temperature becomes $a + \frac{d}{480}$.

4. The last source of explosion to which it is necessary to refer, arises from any casual impediment in the pipes; and it freely admitted, that in frosty weather such an impediment is likely to occur; it has been found to result from other causes, as in the case of extraneous matter accidentally getting into the pipes, an example of which was recently presented in the establishment of Messrs. Wood and Westheads.

In a very obliging letter received, in the course of the investigation, from Sir Robert Smirke, it is stated, that, though he has "never seen the pipes heated sufficiently to ignite wood, except on one occasion," yet, "if a fire is incautiously made when there if a stoppage in the pipes from frost or other accidental cause, the pipe within the furnace may be burst or made red hot near the furnace. I have known the pipe," he adds, "so heated only in one instance, when the red heat extended to a distance of upwards of 12 feet from the furnace."

Sir Robert concludes his letter by suggesting a protective modification of the apparatus. "Therefore," he observes, "to prevent the risk of fire to a building, I would never place the furnace in a room or cellar that is not fire proof, nor would I have the pipes in any part of their circuit in *actual contact* with wood or other combustible material. Security," he continues, "is still more effectually attained by having a safety-valve upon the pipe near the furnace, by which explosion or excess of heat would be prevented."

That which has happened once, may, under the same circumstances, happen again. The exclusion from *actual contact* with combustible materials, could it be permanently ensured, would, when the red heat extended along the pipe upwards of twelve feet, afford, at least, very reasonable grounds for apprehension.

On this system of warming buildings, therefore, danger must be produced from either negligence in the feeding of the furnace, or any stoppage in the pipes: the former evil may be obviated by proper precautions; but the latter, occurring unexpectedly, exists unobserved, and precaution and care must be equally unavailing."

Signed. JOHN DAVIES,
GEORGE VARDON RYDER.

March 10, 1841.

ON THE STYLE OF WREN.

FOLLOWING in the train of Palladian architects comes Wren, another of the school, though exercising its sentiments in a different way. He took from Palladio the idea of modifications, as also he learned from Jones the art of distribution: but then, he also learned a something of the sentiment of English architecture, and so fashioned a style compounded of them all. Not that he deviated from classic rule, or indulged in a detail inconsistent with the whole. This Wren could not do. But inasmuch as the broad masses of Palladio and Jones, were to be sacrificed to the more modest limits of ecclesiastical structures, he had to prepare his features for altitude rather than for breadth. Instead of the artist having to lead the eye upward, he had now to prevent its too hasty ascent, and had to enchain the fancy here or there, as if to compel the eye to wander where otherwise it would instantly soar. In him we see the first architect of his school for beauty of outline and simple elegance of form. In Jones we view the artist more in his dispositions of effect, more in the skilful appropriation of the parts, than in the finished elegance of the parts themselves. In Wren we see more justness of expression, more attention to parts, and richness more tempered with chastity. Jones was the master, natural and often carelessly so, Wren was the master, designing more by principles, and adjusting leading objects ere the richness of ornament appeared. Jones seemed to delight in masses of light and shade, in bold contrasts, in feeling touches. Wren allowed the form of a part to display its dignity, and allowed the contrast to appear in changing outlines. Both took their lesson from Palladio, but Wren studied symmetry the most. Jones took Palladio's errors and revived them; Wren improved upon both in the outline. He took also from the antique to improve, as he also borrowed from Michæl Angelo to surpass him.

Besides this, Wren was the first to bend Roman architecture into the poetry of the Christian without violence to either. This idea springing up on the decline of Roman art, and differently exhibited at later periods and in the middle ages, was perfected by him until classic orders and figures tapered into every variety of elegance. But the spirit of design in Wren was different from that in the olden times. A departure from Roman precedent was then an innovation, in which the purity of Roman detail was *sacrificed* to new forms and increasing altitude, whereas Wren on the contrary, on the restoration of the Basilica, caught the poetry of the monks only to give life and richness to Roman grandeur. Wren's great aim was to give the eye a succession of pyramidal objects, the moment those objects were separated from the mass; there is otherwise a repose and solemn dignity about the lower parts of his edifice. To carry out this idea involved a variety of figures and a change of ornament, which became as essential to the line of ascent as necessary to enrich. The line of ascent is never broken: the eye easily advances, whilst, as it advances, a change as consistent as various appears to meet it. In St. Paul's there is a total contrast between the lower part and the superstructure. In St. Peter's there is a breadth of parts about the superstructure unrelieved. In St. Paul's the horizontal lines growing gradually less prominent towards the dome terminate into sweeping perpendiculars. In St. Peter's the horizontal is never sacrificed for a moment. In St. Paul's the objects multiply in proportion to the height, as also parts get smaller, that is, divisions and subdivisions of parts appear, whilst each grows narrower and more towards a pyramid. Where Wren grew in endless variety, the architects of St. Peter's only tamely ascended.

Wren therefore was the first who whilst he spread grandeur and massive repose beneath, drew the eye by a thousand artificies into the more pleasing beauties above.

If Palladio gave the same spirited outline to the basilica, Wre improved upon him by the variety rather than by the number by his contrivancies.

Thus far we see the peculiar excellencies of Wren, which whilst they mark him as a Palladian architect, evince an original turn for purity of style. It is to be regretted that the works of the French architects influenced him so much in Winchester palace, and affected his designs for palaces and private buildings, for then there would be no blemish upon his architectural fame. As an ecclesiastical architect he ranks as the first, casting by the brilliancy of his genius Palladio and his other followers into the shade. In conclusion, he differed from Jones materially in the position of lines, conceiving only two beautiful positions of straight lines to exist, namely, perpendicular and horizontal, whereas Jones delighted in oblique positions. He saw the great meaning and beauty in these as they existed in the mansions of Palladio, and traced them, as he did all things, to their derivation—nature.

FREDERICK EAST.

March, 1841.

PROGRESS OF RAILWAYS.

London and Brighton Railway.—The works on this great undertaking are approaching completion at even a more rapid pace than the last report of the Directors gave us reason to expect. Both the Merstham and Balcombe tunnels are finished; and a small portion only of cutting remains to be excavated at the approaches. Mr. Rastrick, the engineer, has engaged to convey a party of the Directors on the line from London-bridge to Hayward's-heath in the course of a month. At Clayton the tunnel is nearly finished; and the line will be completed from Brighton to the Hassocks station in June, leaving only the small portion of the line which extends from the Hassocks to Hayward's-heath unfinished. We are assured that the opening of the line throughout the entire distance will take place by August next.—*Brighton Gazette.*

Manchester and Leeds Railway.—The Summit Tunnel, the only portion of this railway which remained unopened, being completed, this line was opened throughout on Monday. The train consisted of two carriages; both being of an entirely new construction, but somewhat different from each other. The body of one of them is about 18 feet by 7, and is 6 feet 6 inches high. There is a compartment in the centre 7 feet square, and is built after the fashion of a gondola. The interior of this compartment is fitted up with splendid mahogany sofas, lined with crimson plush, and trimmed with silk gymp; and the top part above the sofa boxes is composed of plate glass with silk curtains. The two end compartments are open above; but a curtain made of waterproof fabric can be drawn down at pleasure to screen the passengers from the rain, so that in these carriages a person may enjoy all the comforts of a first-class carriage; and at the same time, be enabled to survey the country through which he is passing. The other carriage, the *Tourist*, is similar in its general arrangements, but is fitted up differently. These carriages, which were made by Mr. Melling, of Greenheys, are adapted for summer travelling; there are but two of them, and they are merely for an experiment. The fares in them will, we understand, be the same as in the first-class carriages. The first goods train, which passed through, was drawn by an engine called the *Manchester*, made by Messrs. Sharp, Roberts and Co., of Manchester.—*Leeds Intelligencer.*

Manchester and Birmingham Railway.—In the last number of the Journal we announced that the directors of this great undertaking have selected the design of Messrs. Carpenter and Blythe, of London, for their station, and we think this selection is one which will have the effect of adding another fine specimen of architecture to Manchester. The designs have been submitted to public exhibition at the Victoria Gallery. The approach to the station commences in Ducie-street, London-road, from which an inclined carriage way leads on to the railway, which is thirty-two feet above the level of Store-street. The internal arrangements of the station, of which we have been favoured with a sketch, are exceedingly convenient, and appear to combine all the improvements in railway engineering, with the addition of some novelties, for which the directors are indebted to their distinguished engineer, G. W. Buck, Esq. Of these the most striking are, the situation of the engine stable and the construction of the turn table, or apparatus for moving the engines and carriages from one line of rails to another. The engine stable, which will contain stalls for six engines and tenders, is placed at the terminus of the rails, instead of being at a distance from the station, the position usually adopted, by which plan much time will be economised in the dispatch of the trains. By this arrangement the engines, after bringing the trains into the station, can be detached therefrom and turned round without the engine and tender being uncoupled, and then go into the stable to remain there, or to receive coke and water, and return upon another line of rails to the departure side of the station, to take out another train, or proceed to the principal engine depôt at Longsight. This turn table consists of a circular plate of iron, thirty feet in diameter, to be moved by a small steam engine proposed to be erected. The mode of turning the table is very ingenious. Instead of the ordinary method of employing manual labour, Mr. Buck intends to make a portion of the under side of the plate answer the purpose of a pulley, a strap or chain being passed round it, and a fixed pulley in connexion with the steam engine, and by these means the ponderous machine and its load will be moved round with the greatest ease, and the labour of at least half a dozen men will thus be saved.

STEAM NAVIGATION.

The United Steam Frigate Missouri.—From the New Orleans Picayune.—This magnificent vessel is constructed principally of live oak from Attakapas, in this state, and her entire cost is 500,000 dollars. In her rig she will resemble a handsome bark, and her builder has constructed the hull so admirably, as to render her, as a sailing vessel, a No. 1 of the United States navy. She will sail the greater part of the time, as her bunkers only carry about 800 tons of coal, or sufficient for 20 days' steaming. Her spars, particularly the foremost and mainmast, are as heavy as those of a first class frigate, and she is so constructed as to be able to ship and unship her paddle-wheels with the greatest facility. She is pierced for 26 guns, but will carry but 18—6 aft the wheel-house, and 3 forward of it on each side. She is to carry two 10-inch guns forward, which are to traverse the greater part of a circle on a swivel; these two guns will be able to carry shot nearly 100 pounds weight, as 8-inch guns carry 64 lb. shot. The other 16 guns are to be 8-inch bore. On account of the result of various trials, the whole of ordnance is to consist of Paixhan guns. She will be ready for sea in July next.

Taylor's Improvements in Steam Boats.—We have been informed that Capt. Taylor, of her Majesty's ship San Josef, has lately been engaged in a course of experiments in Hamoaze, with a view to the prevention of collisions between steam-vessels, and steam and sailing vessels, such as those which have of late been of so frequent occurrence, and which have been attended with such deplorable loss of property and life. Our informant states that those experiments promise the most satisfactory result. He says that Captain Taylor "has discovered a plan by which the steam boat will be placed completely under the control of the persons on deck, as, immediately danger is seen, the steamer can be stopped, or turned round upon her own centre, and within her own length, without stopping the engine, or calling to the engineer." We have been furnished with some details relative to Captain Taylor's invention, which we withhold for the present, as we understand he contemplates taking out a patent; but should his discovery, when farther tested, be found practicable, and should it have the effect of preventing, in future, such melancholy consequences as those which resulted from the late collision between the Nottingham and Governor Fenner, this able and meritorious officer will have rendered a most important service to the interests of humanity.—*Times.*

British Queen and President Steam Ships.—It was whispered in the more select commercial circles on Monday, that the British and American Steam Navigation Company had sold their magnificent ships, the British Queen and President, to the Belgian Government. The President is now on her voyage from America, and will, it is added, have to be surveyed before the contract can be considered definitively concluded; but, if our information be correct, of which we have no doubt, the British Queen has already been "proved," and is, in fact, the property of the Belgian Government. The future destination of the two vessels is scarcely less certain. The Belgians are anxious to push their commerce in every possible way, and we believe it will turn out that the British Queen and President have been purchased with the view of forming a regular steam communication between Antwerp and New York. —*Morning Post*

The General Steam Navigation Company.—The half-yearly meeting of the proprietors was held on Tuesday, the 23rd ult., at the office in Lombard-street. From the report of the directors it was collected that the operations of the past year had been attended with success, and that the affairs generally were in a course of prosperous advancement. Full explanations were entered into upon various points interesting to the proprietors, and appeared to afford much satisfaction. It was resolved, that a considerable sum should be appropriated toward the cost of two large steam ships of 650 and 900 tons, now building by Messrs. Green, Wigram, and Green, and the customary dividend and bonus were declared.

MISCELLANEA.

Artesian Well at Vienna.—For some time past these works had been going on in the vicinity of the barracks in the Corn Market, when, after digging 96 Austrian fathoms, the undertaking was crowned with complete success, in the first week of the present month. The water rushes up in such abundance, that it has been estimated to exceed 12,418 gallons per day, and when it first made its appearance, it was with some difficulty that several shops in the neighbourhood were preserved from inundation.

Artesian Wells in the Oasis of Thebes.—This Oasis is twenty-three leagues in length, and from two to four in breadth, and is studded with Artesian wells, which have been noticed by Arago. The ancient inhabitants used to dig square wells through the superficial vegetable soil, clay, marl, and marly clay, down to the limestone, from twenty to twenty-five metres in depth. The last rock contains the water which supplies the wells, and is called by the Arabs *Agar el moya*. In the rock, holes were bored from four to eight inches in diameter. These holes were fitted with a block of sandstone supplied with an iron ring, in order to stop the supply, when there was danger of inundating the country.

Crowland Abbey.—A new gallery is in course of erection in this sacred edifice capable of accommodating 150 sitters, which, with other improvements made, and in contemplation, will add greatly to the beauty of this truly "majestic pile of Gothic grandeur."

New Pier at Chelsea.—Lord Cadogan has given instructions for a splendid pier to be erected in Cheyne-walk, Chelsea, opposite the place where the Bishop of Winchester's palace formerly stood, and Mr. Lewis Cubitt has taken the [illegible] street from the water [illegible] to be [illegible] the iron [illegible] Friday [illegible]

Asphalte.—[illegible] the Directors of the [illegible] Asphalte Company [illegible] Patent [illegible] contract with the Greenwich Railway Company [illegible] the [illegible] their Junction line, to the extent of 240,000 superficial feet. It is [illegible] that the floors of the several cells of the model prison [illegible] with this material.

New Lighthouse at Plymouth.—The ceremony of laying the foundation stone of the lighthouse intended to be built on the west end of the Plymouth breakwater, took place [illegible] the weather was delightfully serene, which added much to the [illegible] of the occasion. The stone having been prepared it was [illegible] and [illegible] Rear Admiral Warren, Admiral Superintendent of the [illegible] having plumbed it, spread the mortar, and [illegible] coins of the realm were deposited beneath the stone.

Engineering Honours.—We have much [illegible] to announce that Isambard Brunel, the engineer-in-chief of the Thames Tunnel, has been knighted by Her Majesty; we hope that this is the commencement of [illegible] [illegible] to the [illegible] profession. [illegible]

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 23RD FEBRUARY, TO 25TH MARCH, 1841.

Six Months allowed for Enrolment.

GEORGE ENGLAND, of Westbury, Wiltshire, clothier, for "*improvements in machinery for weaving woollen and other fabrics, and for twisting, spooling, and warping woollens, also for improvements in the manufacture of woollen doeskins.*"—March 2.

JOHN WILKIE, Nassau-street, Mary-le-bone, upholsterer, and JOHN CHARLES SCHWIESO, of George-street, Saint Pancras, musical instrument maker, for "*improvements in constructing elastic seats or surfaces of furniture.*"—March 2.

HENRY NEWSON BREWER, of Jamaica Row, Bermondsey, mast and block maker, for "*an improvement or improvements in wooden blocks for ships, rigging, tackles and other purposes, where pullies are used.*"—March 3.

JOHN RAND, of Howland-street, gentleman, for "*certain improvements in machinery for the manufacture of frame work knitting or hosiery.*"—March 6.

THOMAS SPENCER, of Liverpool, carver and gilder, for "*an improvement, or improvements in the manufacture of picture and other frames, and cornices applicable also to other useful and decorative purposes.*"—March 8.

JOHN VARLEY, of Bayswater Terrace, Bayswater, artist, for "*an improvement in carriages.*"—March 8.

JOHN WILLIAM NEALE, of William-street, Kennington, engineer, and JACQUE EDOUARD DUYCK, of Swan-street, Old Kent-road, commission agent, for "*certain improvements in the manufacture of vinegar, and in the apparatus employed therein.*"—March 8.

BENJAMIN SMITH, of Stoke Prior, near Bromsgrove, butcher, for "*an improved apparatus for making salt from brine.*"—March 8.

JOHN WALKER, of Crooked-lane, King William-street, for "*an improved hydraulic apparatus.*"—March 8.

RICHARD LAWRENCE STURTEVANT, of Church-street, Bethnal Green, soap manufacturer, for "*certain improvements in the manufacture of soap.*"—March 8.

THOMAS JOSEPH DITCHBURN, of Orchard House, Blackwall, shipbuilder, for "*certain improvements in ship building, some, or all of which, are applicable to steam boats, and boats, and vessels of all descriptions.*"—March 8.

ANTHONY TODD THOMSON, of Hind-street, Manchester-square, doctor of medicine, for "*an improved method of manufacturing calomel and corrosive sublimate.*"—March 8.

STEPHEN GOLDNER, of West-street, Finsbury Circus, merchant, for "*improvements in preserving animal and vegetable substances and liquids.*"—March 8.

JOHN WERTHEIMER, of West-street, Finsbury Circus, printer, for "*improvements in preserving animal and vegetable substances and liquids.*" (A communication.)—March 8.

THOMAS CLARK, professor of chemistry, in Marischal College, Aberdeen, for "*a new mode of rendering certain waters (the water of the Thames being among the number,) less impure and less hard for the supply and use of manufactories, villages, towns, and cities.*"—March 8.

JOHN BAPTIST FRIED WILHELM HEIMANN, of Ludgate Hill, merchant, for "*improvements in the manufacture of ropes and cables.*" (A communication.)—March 8.

JOHN DOCKREL, of Galway-street, Saint Luke's, gas fitter, for "*an improvement, or improvements on gas burners.*"—March 15; two months.

RICHARD LAMING, of Gower-street, Bedford-square, surgeon, for "*improvements in the production of carbonate of ammonia.*"—March 15.

WILLIAM NEWTON, of Chancery-lane, civil engineer, for "*certain improvements in machinery or apparatus for picking and cleaning cotton and wool.*" (A communication.)—March 15.

ROBERT WARINGTON, of South Lambeth, Surrey, gentleman, for "*improvements in the operations of tanning.*"—March 16.

JOSEPH MAUDSLAY, of Lambeth, Surrey, engineer, for "*an improvement in the arrangement and combination of certain parts of steam engines, to be used for steam navigation.*"—March 16.

WILLIAM NEWTON, of Chancery-lane, civil engineer, for "*improvements in spinning and twisting cotton, and other materials capable of being spun and twisted.*" (A communication.)—March 16.

GEORGE LOWE, of Finsbury Circus, engineer to the chartered gas company, for "*improved methods of supplying gas under certain circumstances, and of improving its purity and illuminating power.*"—March 16.

CHARLES BENT DYER, of Pary's Mine, Anglesea, mine agent, for "*an improved method of obtaining paints or pigments by the combination of mineral solutions and other substances.*"—March 16.

LAURENCE KORTRIGHT, of Oak Hall, East Ham, Essex, Esq. for "*certain improvements in treating and preparing the substance commonly called 'White Bone,' and the fins and such like other parts of whales, and rendering the same fit for various commercial and useful purposes.*" (A communication.)—March 17.

WILLIAM THOMPSON CLOUGH, of Saint Helens, Lancaster, alkali manufacturer, for "*improvements in the manufacture of the carbonates of soda and potash.*" (A communication.)—March 17.

HENRY AUGUSTUS WELLS, of Regent-street, gentleman, for "*improvements in [illegible] dressing [illegible].*" (A communication.)—March 17.

JOSHUA FIELD, of Lambeth, engineer, for "*an improved mode of [illegible] the operation of connecting, and disconnecting [illegible] steam engines, [illegible] paddle wheels, used for steam navigation.*"—March 22.

RICHARD BARNES, of Wigan, Lancaster, engineer, for "*certain improvements in machinery, or apparatus for raising or drawing water and other fluids.*"—March 22.

ANTHONY THEOPHILUS MERRY, of Birmingham, refiner of metals, for "*an improved process, or processes for obtaining zinc and lead from their respective ores, and for the calcination of other metallic bodies.*"—March 22.

ROBERT WALTER WINFIELD, of Birmingham, merchant and manufacturer, for "*certain improvements in, or belonging to metallic bedsteads, a portion of which may be applied to other articles of metallic furniture.*"—March 22.

ROBERT GOODACRE, of Ullesthorpe, Leicestershire, for "*an improved mode of weighing bodies raised by cranes or other elevating machines.*"—March 22.

DAVID NAPIER, of Mill Wall, engineer, for "*improvements in propelling vessels.*"—March 22.

ACHILLE ELIE JOSEPH SOVITAS, of George Yard, Lombard-street, merchant, for "*improvements in apparatus for regulating the flow of fluids.*" (A communication.)—March 22.

WILLIAM BUCKNELL, of Westminster, gentleman, for "*improvements in applying heat for the purpose of hatching eggs, which improvements are also applicable to other useful purposes where heat is required.*"—March 22.

MORRIS WEST RUTHVEN, of Rotherham, engineer, for "*a new mode of increasing the power of certain media, when acted upon by rotary fans or other similar apparatus.*"—March 22.

ROBERT COOK and ANDREW CUNNINGHAM, of Johnstone, near Glasgow, engineer, for "*improvements in the manufacture of bricks.*"—March 22.

MOSES POOLE, of Lincoln's Inn, gentleman, for "*improvements in stretching cloths.*" (A communication.)—March 22.

JOSEPH WRIGHT, of Carisbrook, Isle of Wight, mechanic, for "*improvements in apparatus used for dragging or skidding wheels of wheeled carriages.*"—March 22.

THOMAS WRIGHT, of Church Lane, Chelsea, Lieutenant in Her Majesty's Navy, for "*certain improvements applicable to railway and other carriages.*"—March 22.

EDWARD FINCH, of Liverpool, ironmaster, for "*improvements in propelling vessels.*"—March 25.

GOLDSWORTHY GURNEY, of Bude, Cornwall, Esq., for "*improvements in the production and diffusion of light.*"—March 25.

ERRATA IN LAST MONTH'S JOURNAL.

Page 75, col. 1, two lines from bottom, for "[illegible]style" read "[illegible]style."
Page 77, col. 2, line 21, for "as one of" read "is one of."

TO CORRESPONDENTS.

We shall feel obliged if O. of Dublin, will favour [illegible] with any information respecting the progress of architecture or engineering works in Ireland.

We must decline inserting any further communication respecting Mr. [illegible]'s History of the London & Birmingham Railway, as it will involve us in [illegible] proceedings.

Upon consideration we must decline inserting H.'s communication [illegible] the reviewer's observations on Parsey's new work on Perspective; it is [illegible] for the reviewers to please all parties.

We shall be glad to receive from A Subscriber at Oxford, the [illegible] of the Oxford Architectural Society, and of the Camden Society.

Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," No. 11, *Parliament Street, Westminster.*

Books for Review must be sent early in the month, communications [illegible] before the 20th (if with drawings, earlier), and advertisements on or before the 25th [illegible].

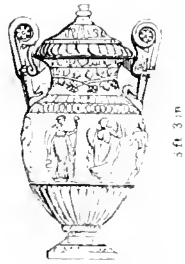
Vols. I. II. and III. may be had, bound in cloth, price £1 each Volume.

No. 47.—Grotesque Mask Vase.

No. 62.—Gothic Vase

No. 108.—Enriched Etruscan Urn.

No. 59.—Oriental Lotus Vase

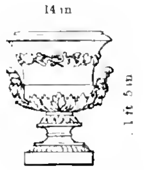


No. 119.—From the British Museum.

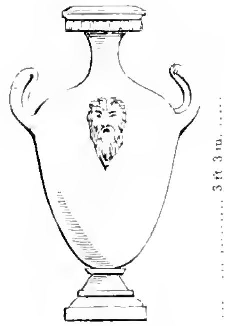
The same 2 ft. 8 in.

Also without Top, 17 in

No. 43.—Antique Festoon Vase.

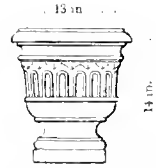


No. 46.—Convolvulus Wreath Vase



No. 103.—Greek Urn

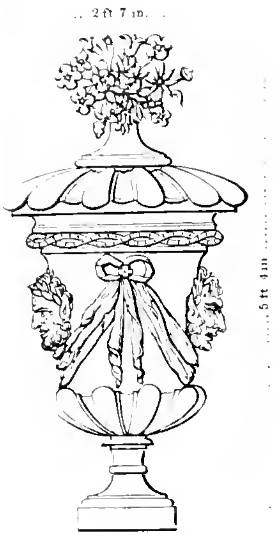
The same with Three Handles.



No. 53.—Maltese Vase.

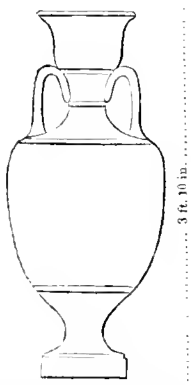
Also one 17 in. high, and 15 in. diam

No. 101.—Plain Greek Urn

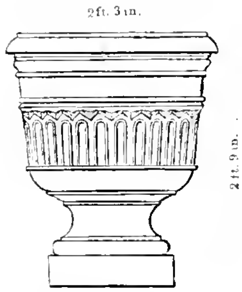


No. 32.—Bouquet and Mask Vase. (Italian.)

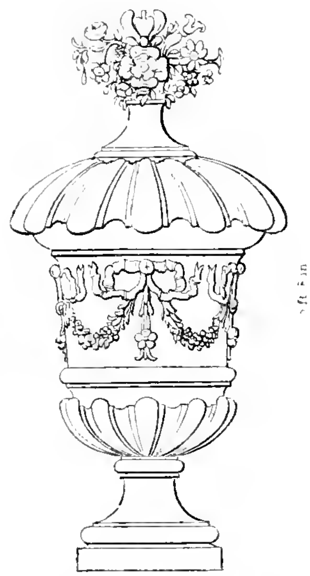
Vase for Ornamental Chimney Pot.



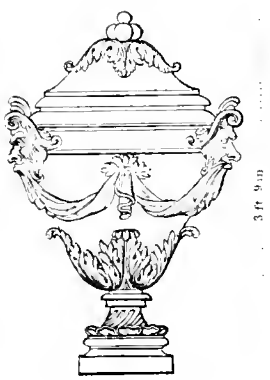
No. 106.—Plain Etruscan Urn.



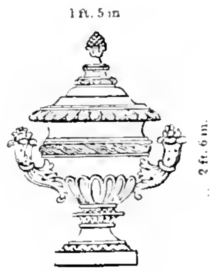
No. 51.—Maltese Vase



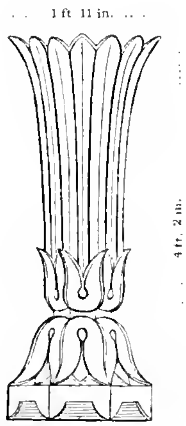
No. 33.—Bouquet and Festoon Vase (Italian.)



No. 110.—Draperied Urn



No. 102.—Guilochi Vase.



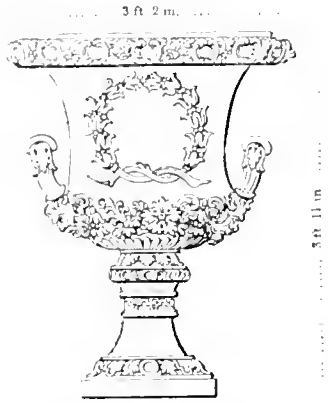
No. 56.—Oriental Lotus Vase.

No. 115.—The Bayswater Vase

No. 112.—Enriched Urn, with Cupids and Lions.

The Prices of the following Vases range from Ten Shillings to Thirty Guineas, Packing extra.

No. 9.—Borghese Vase



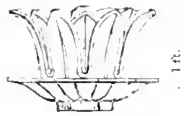
No. 40.—French Foliage Vase with Wreaths.

The same without Wreaths.

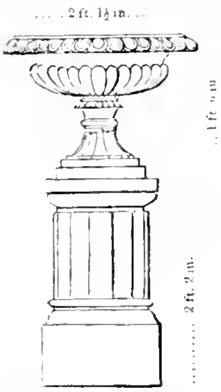
No. 11.—Grecian Vase.

No. 70.—The Bishop's Vase.

Also the same quite plain



No. 99.—Cup and Saucer.

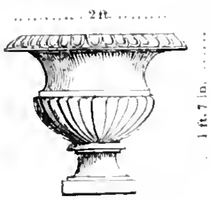


No 199.—Egham Tazza, and 672.—Small Fluted Column Pedestal.

(For Creeping Plants.)

No. 30.—A Reservoir Vase (Maltese.)

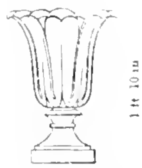
No. 14.—Grecian Vase on Plain Pedestal.



No. 65.—Isle of Wight Vase.

Also the same with Wreath of Ivy Leaves.

And another, plain, 15 in. diam.



No. 96.—Tulip Vase

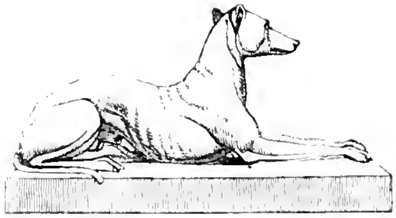
Also one 17 in. high

No. 29.—Figured Grecian Vase.

No. 38.—The Warwick Vase

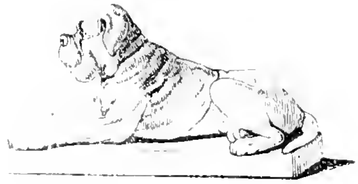
No. 35.—The Tamworth Vase

Also a Companion.



4 ft.

The Dog of Alcibiades
(Size of the original.)
Also the reverse, and one 16 in. high.



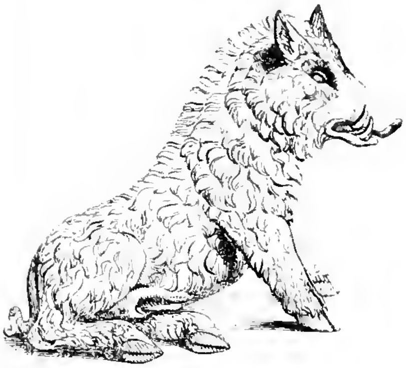
3 ft. 8 in.

The Old English Mastiff.
Also several other Dogs.

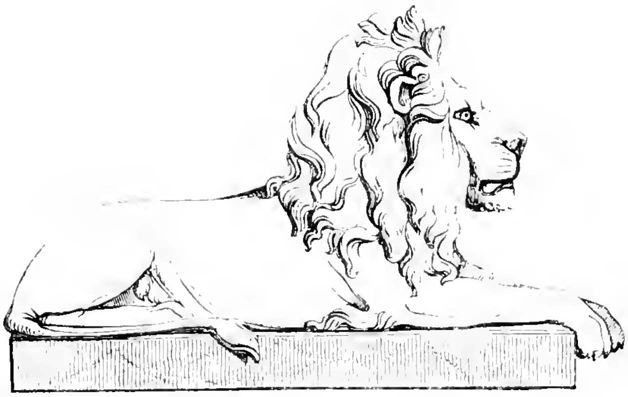
2 ft. 9 in.

2 ft.

Also an Elephant, and other small Models of Animals.



The Florence Boar. (Full life size.)
Also the reverse.

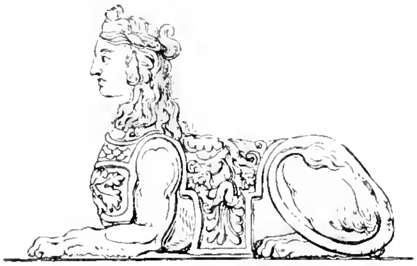


6 ft. 5 in.

Modelled from Nero.

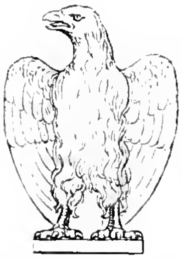
3 ft. 2 in.

3 ft. 3 in.



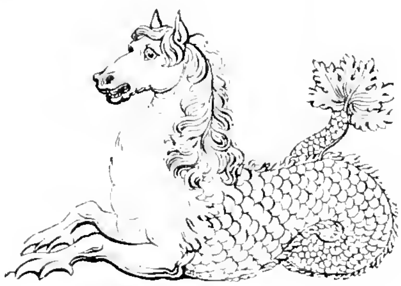
5 ft. 3 in.

Also another Model, 7 ft. 7 in.
Ditto, 5 ft.
A Pair of Lion and Lioness sleeping, 3 ft. each.



2 ft. 11 in.

Also a large Spread Eagle, 6 ft. 7 in. wide



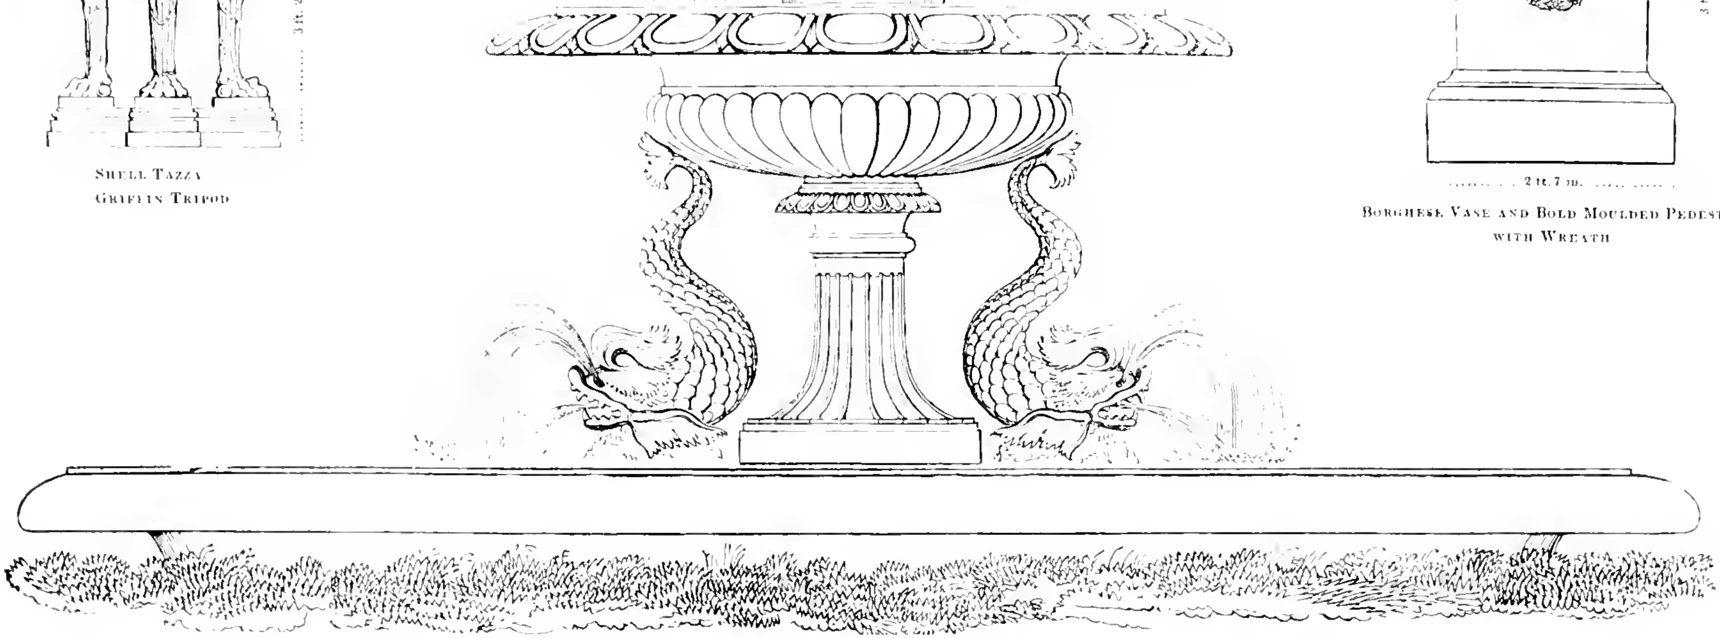
4 ft. 2 in.

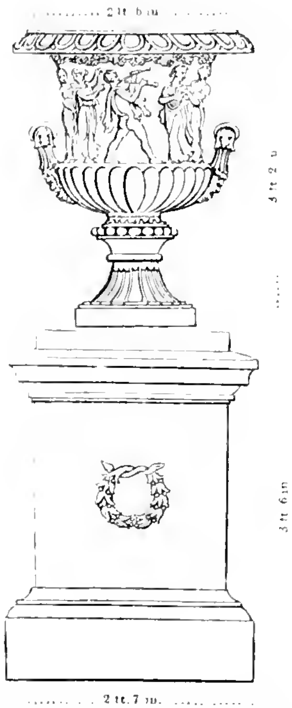
2 ft. 7 in.

Also another Model, with closed wings, 14 in. high.

A Set of Four Pigeons in different postures and other Birds, life size.

Shell Tazza
Griffin Tripod





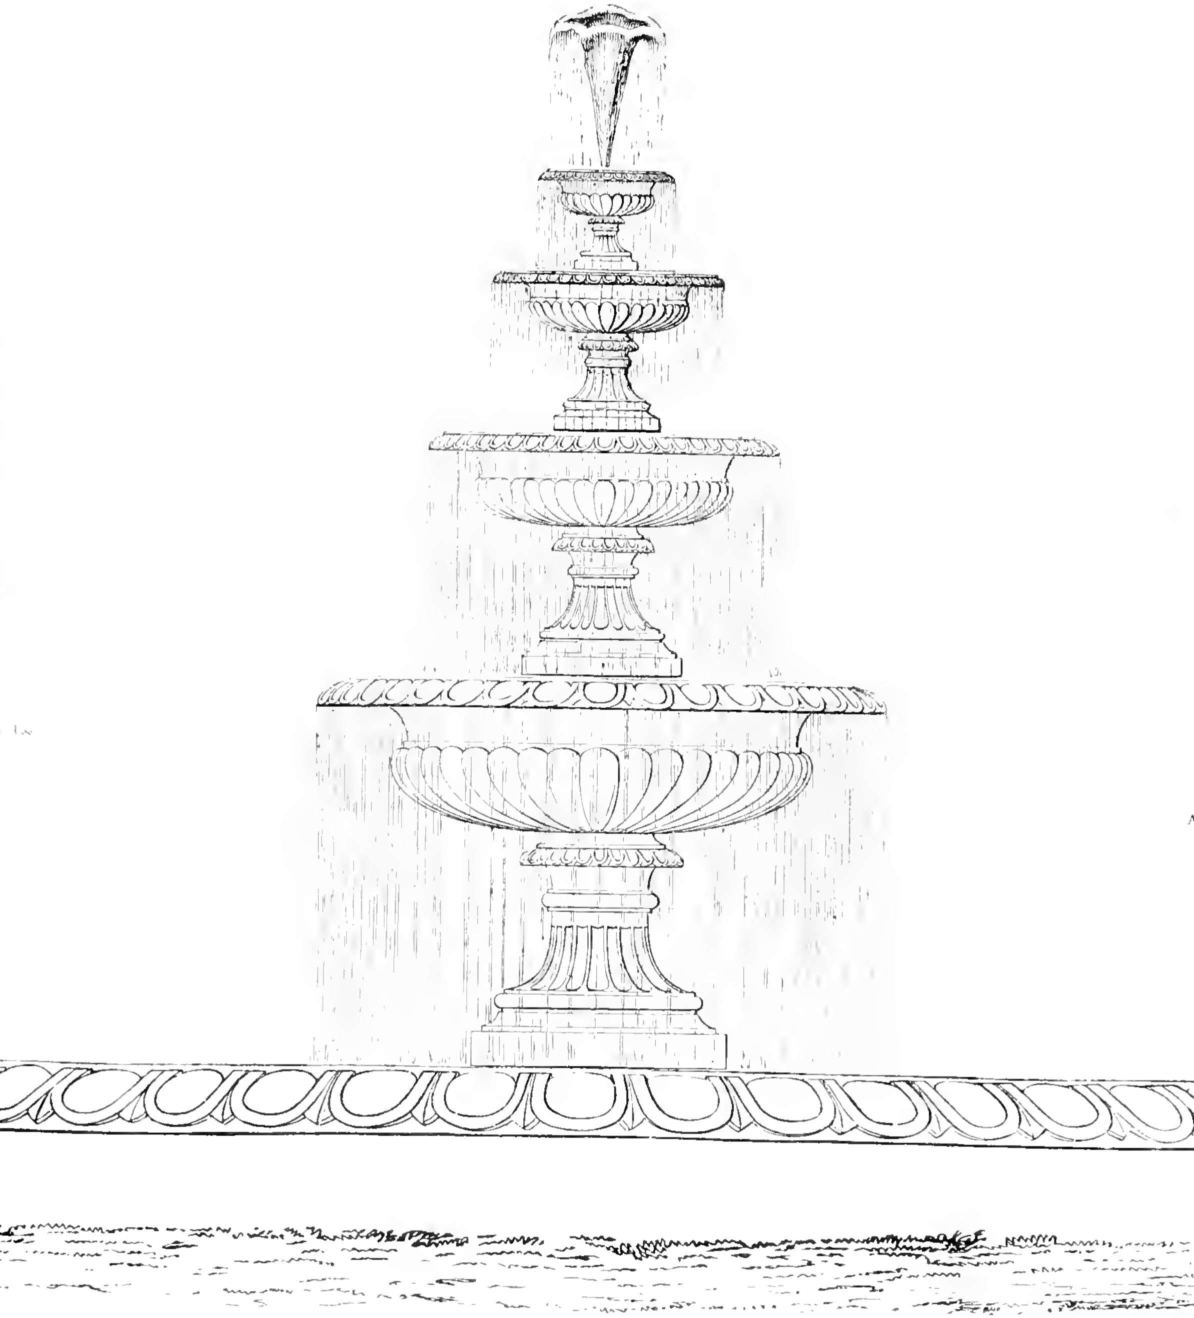
Borghese Vase and Bold Moulded Pedestal
with Wreath

THE SYPHON FOUNTAIN.

The Syphon Fountain is constructed upon the simple principle of natural intermitting springs; thus, the above Tazza is divided into two or more compartments, and pipes are laid from each to the several Dolphins below, the pipes being bent at the top. as soon as the compartments become quite full, and not till then, the contents will be rapidly drawn off through the Dolphins, and thus one or more of them may be seen playing, as their respective compartments become filled

AUSTIN AND SEELEY'S ARTIFICIAL STONE ORNAMENTS.

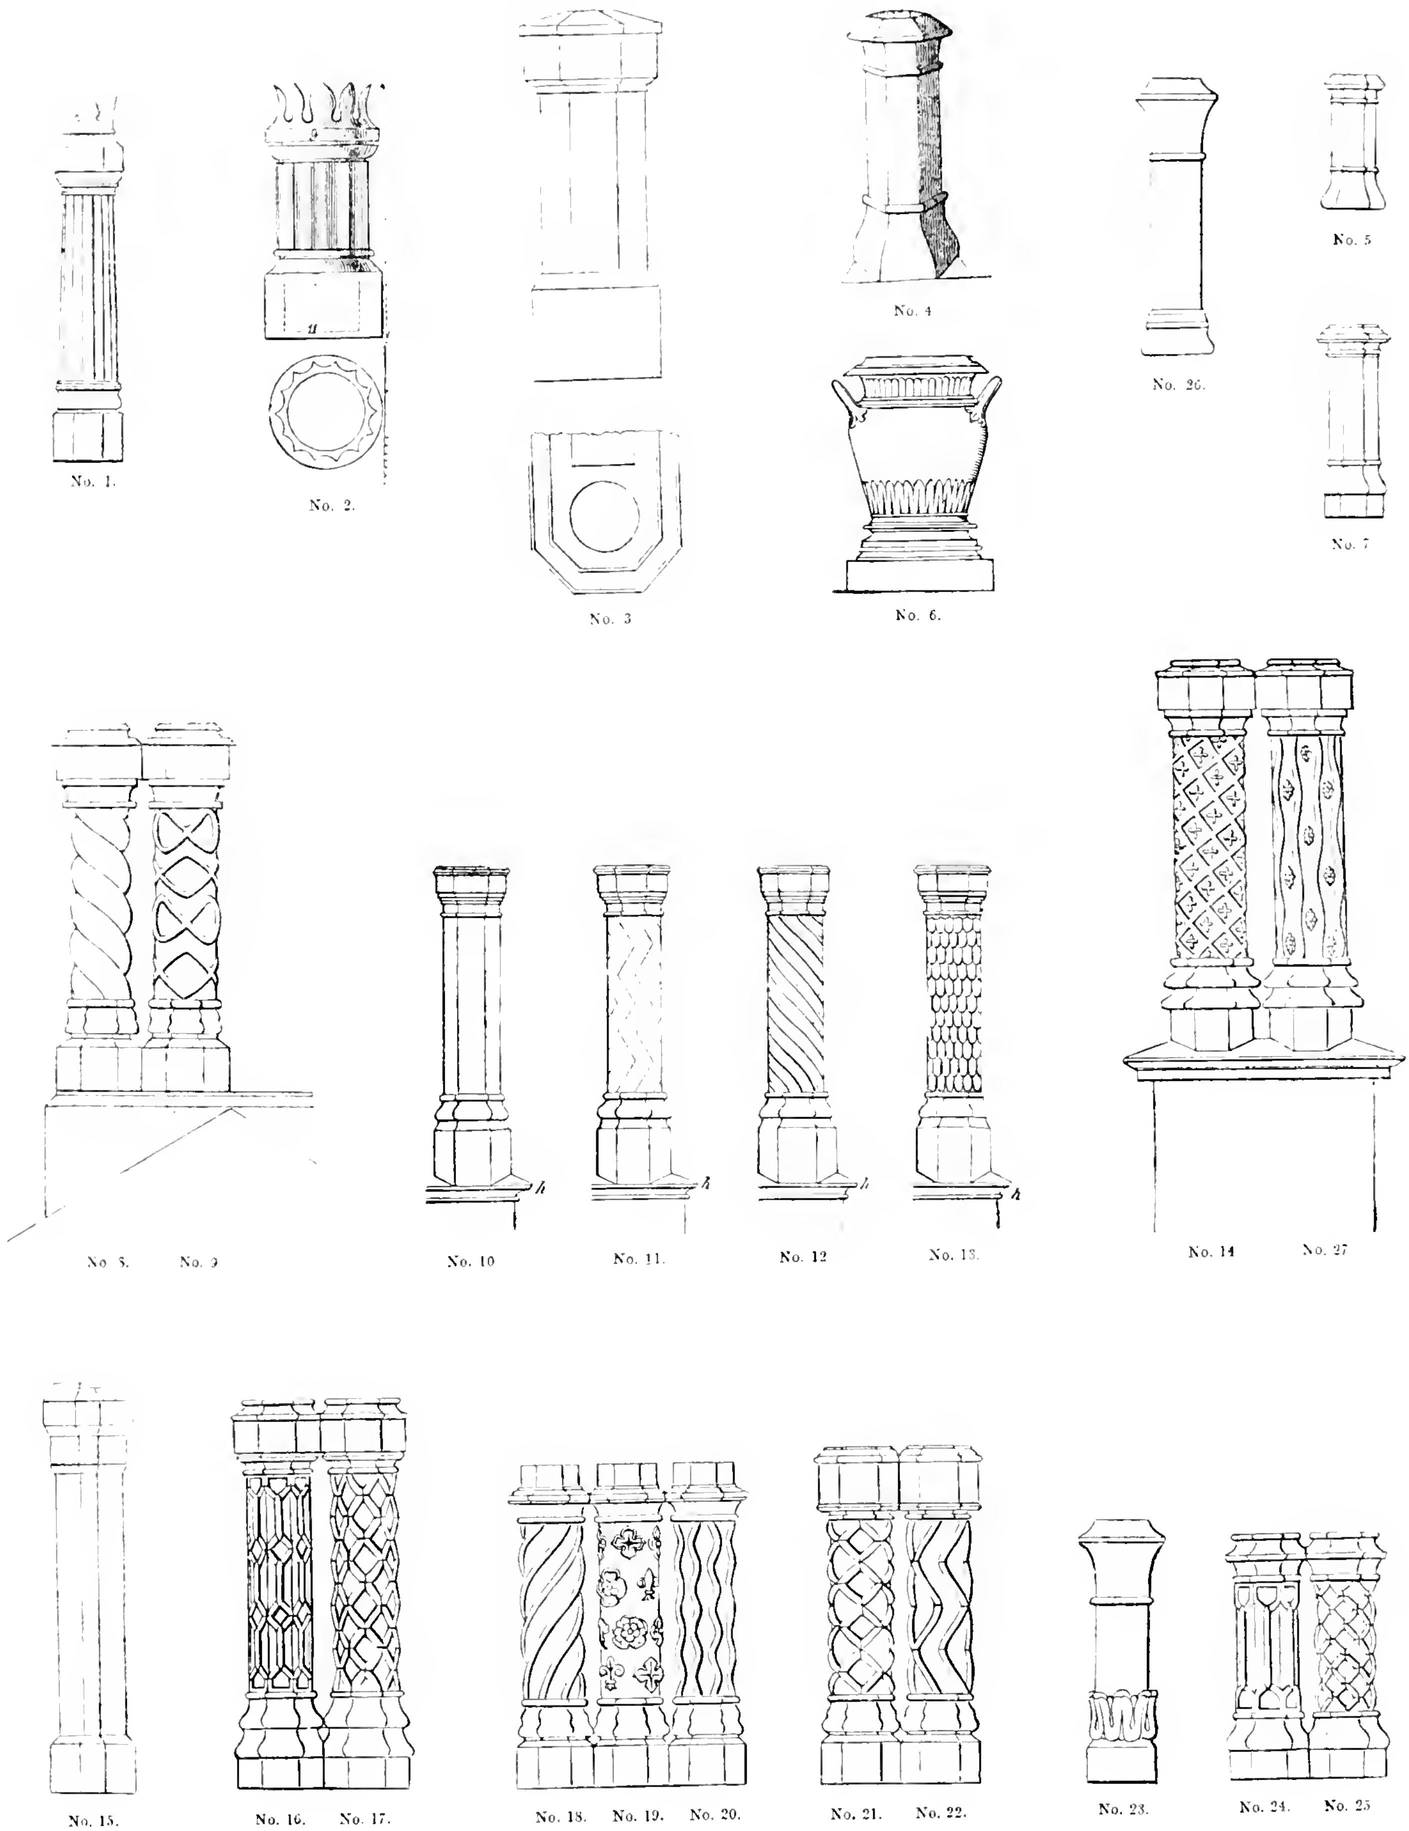
A Variety of Shells, from 25s. to £15 15s.



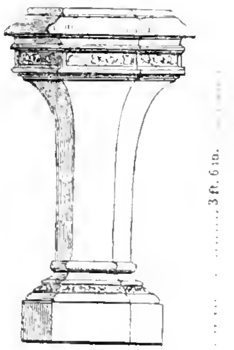
Set of Four Grecian Tazzas, lower one, 6 feet diameter, and lower Basin, with Enriched Rim, 20 feet diameter.

Antique Vase and Pedestal

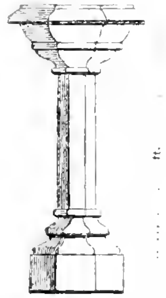
The following are selected from nearly one hundred varieties of Chimneys.



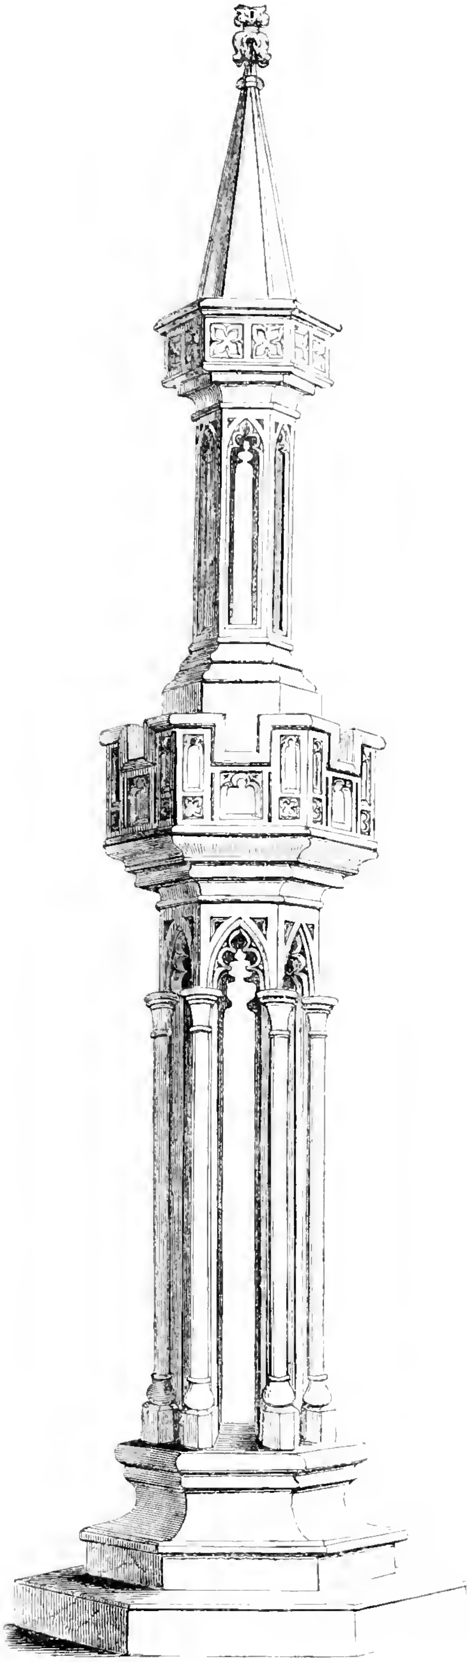
Fonts made to any Design.

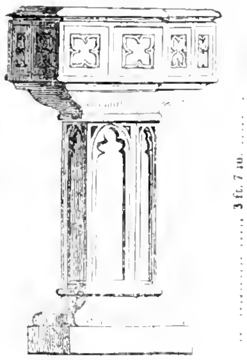


No. 552.—Font, with Wreath of Ivy Leaves.
No 553.—The same, without Wreath

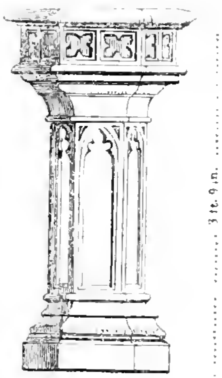


No. 556.—Plain Octagon Font.

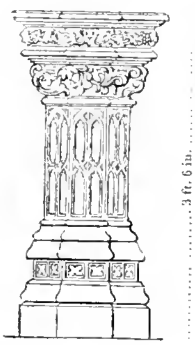




No. 559.—Gothic Font,
With large Top, for immersion



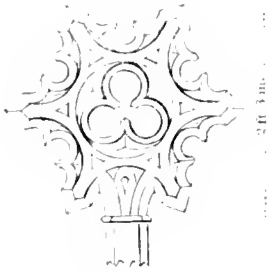
No. 557.—Gothic Font, with Perforated Shaft.
The same, with solid shaft.



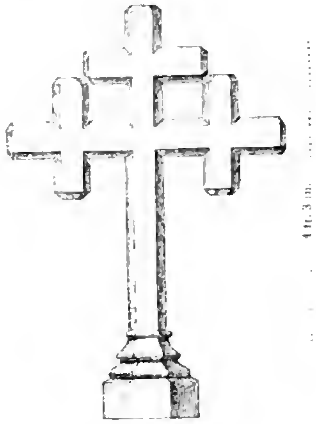
No. 547.—Rich Gothic Font
Designed from Henry VII.'s Chapel.

No. 563.—Early English Font

A. and S. have many other Fonts, slightly varied from the above.

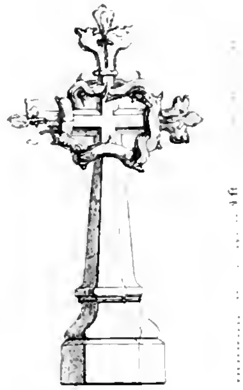


No. 543.

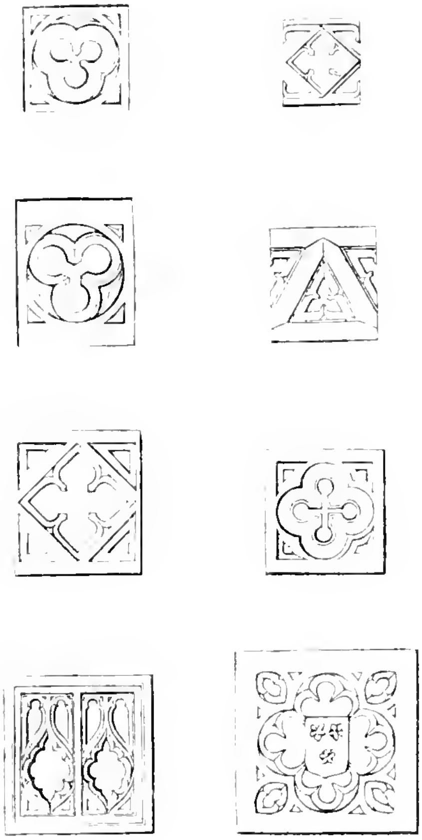


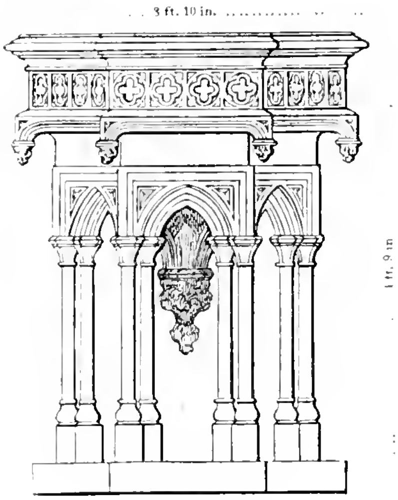
No. 539.

Also Five other Crosses.



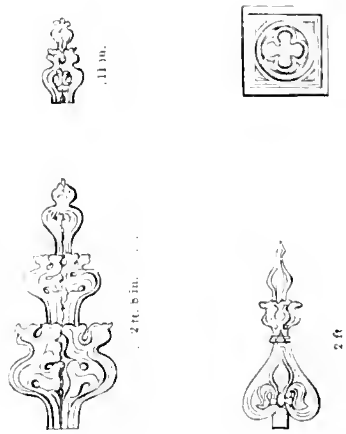
No. 540.





HEXAGON GOTHIC FONT.

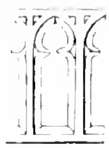
VERGE BOARD.



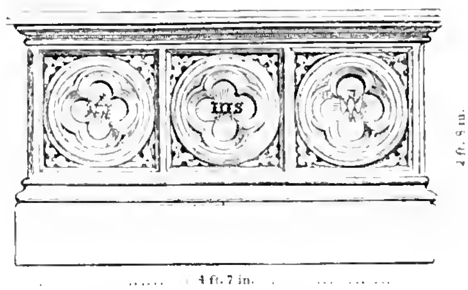
Also several other Finials.

(Drawn to inch scale.)

Nearly One Hundred Corbels and Brackets.

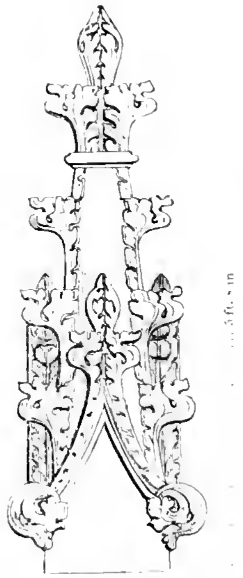


Also a Gothic Figure



COMMUNION TABLE (the ends plain).

Also the same size, with plain quatrefoil



Also other Pinnacles, 3 ft. 7 in.; 2 ft. 1 in.; 1 ft. 2 in

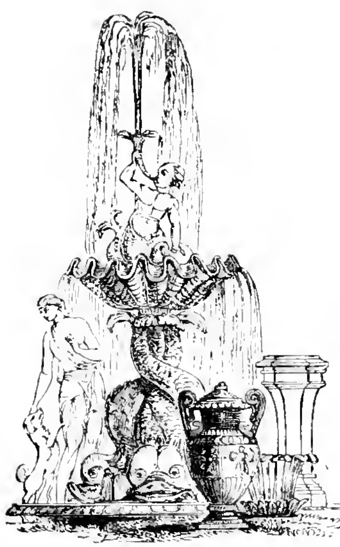
NEW AND USEFUL INVENTIONS, No. 3.

By Philotechnicos.

(With 8 pages of Wood Engravings.)

Having been prevented from continuing the series of papers which I had commenced in some of the early numbers of the Journal, and having been advised by some of my friends that notices of this kind were not only of value to the profession, as pointing out many things highly useful to them, and well deserving of encouragement, but also to the student and inventor by keeping a record of the attempts of others, I have been induced to resume my peripatetic exertions. My object being to bring before the world not only present scientific novelties, but many valuable inventions, which either lie dormant or are comparatively unknown, from their merits not having been sufficiently brought before the public; it is my intention to continue my visit to the studio, the workshop, and the manufactory, to search out and bring to light what I consider deserving of the patronage of the profession, at the same time that I rely upon their assistance to enable me satisfactorily to carry out my inquiries. Any communication therefore on these subjects, forwarded through the Editor of this Journal, I shall be happy to receive, so as to make this series of papers an interesting and valuable record of the meritorious exertions of ingenious individuals. From my present notes, I have contributed this paper, in which, if I have only been able to do justice to the labours of one, it must be remembered that it is not subjects which are wanting, but space.

AUSTIN AND SEELEY'S ARTIFICIAL STONE-WORKS, NEW ROAD, REGENT'S PARK.



The excellence of the composition, the symmetrical forms of the many elegant vases and tazzas, the well modelled and numerous architectural ornaments at this establishment claim particular attention. Those two noble vases the Borghese and Medici have been restored from the originals to their full size, and while without serious alteration they have been so managed as to pair together. The noted Warwick vase reduced to half the original size, and several others from the antique, are good specimens of the material and workmanship of this manufactory, in which may be found vases of all sizes and design, from the chaste Greek to the overwrought Maltese, many of which from their moderate cost may often be introduced with advantage.

The several fountains exhibited display, great taste and ingenuity: combinations of tazzas, dolphins, shells, and foliage, are cleverly contrived, with many beautiful devices for jets d'eau, which by their introduction will give great interest to the garden or conservatory, and tend much to enliven the scenery. Tazzas in gardens may be used for gold and silver fish, and serve as reservoirs for watering the garden. Much labour might be avoided if water were laid on to pedestals placed in several parts of the garden, and furnished with stop-cocks and flexible tubes concealed in them; the tube may be furnished with jets and roses for watering the plants with greater facility, and for the sake of ornament, a vase or figure should surmount the pedestal, and render it a pleasing object. Where a fountain is desired and water scarce, it may be so constructed as to use the same water over and over again, by raising it up into a vase or reservoir by a force pump hidden in the pedestal, or should there be a running stream in the neighbourhood, a small water-wheel or hydraulic ram might be applied by which the water can be raised to almost any height. The hydraulic ram is frequently used to force a portion of the waste water back again to the reservoir, which it will do by self-action. Most of these contrivances may be seen in action, Mr. Austin having well studied this interesting branch of his business, and expended great time in perfecting it.

The architectural ornaments consist of a variety of Gothic finials, pinnacles, crosses, panels, fonts, traceries, parapets, copings, and other decorations. The commissioners for building new churches might with advantage pay a visit here, and be convinced that ornament and economy may be combined, when they see that by the introduction of artificial stone, they would be enabled to enrich their buildings and avoid that barn-like appearance of many of the modern churches. To ecclesiastical buildings where repetition of ornament is so frequent, Austin and Seeley's artificial stone is well adapted, and has been applied with great success; its appearance, although only half the cost, is nearly equal to stone, and in point of durability far surpasses the softer kinds, and it is only equalled by the best Portland. All the dressings might be of this material, while by the building being faced with patent pressed malms in lieu of the frigid looking white bricks, now frequently used, a more cheerful appearance might be obtained and some architectural character.

There are many other ornaments suitable for building purposes, such as balustrades, columns, gate piers, porticos, brackets, trusses, &c., in all styles. The chimney-shafts are of great variety, and I would here beseech the architect to turn his particular attention to this subject, and to use his utmost exertion to reform those miserable looking specimens of ugliness, chimney pots, that now too frequently figure on the tops of houses, being usually of a most common place form, and as much disconnected from the style of the building as the figure of Nelson would be from a Corinthian column. They ought to be designed for what they really are—terminations to the building—and consequently finished as a sort of capping to the chimney shaft, and have some decided connection therewith. Such the Italians generally considered them, and thus has Mr. Barry very judiciously introduced them at the Reform Club House, where the chimney shafts are surmounted by a projecting cornice supported by trusses, and form truly ornamental objects, adding to the effect of the building rather than detracting from it, as in too many cases chimney shafts and pots usually do. Thus utility is reconciled with ornament, without any attempt to disguise what all the world knows to be connected with the greatest comfort in the house.

The flat roofs, floors and steps exhibited at these works deserve inspection; the front yards have been excavated, and workshops formed below the surface of the ground, and covered with this material, the lightness and strength of which is astonishing. The terrace roofing is laid with plain tiles in three courses, and rendered on the top, to the thickness in all of about four inches, carried over by arches slightly cambered springing from small brick piers, and tied by light iron rods, which form their chord line. These flats have an immense weight upon them, and are each, as it were, in one piece, having no perceptible joint, by which they are made completely water tight, at the same time that they can be easily cleaned. It may be well to remark that many flats have been formed of cement and tiles, and afterwards condemned as not being impervious to wet, this is, however, for the most part, a mistaken notion—it is true wet frequently makes its appearance, and is often seen dripping from the ceiling, but this almost invariably is caused by condensation—particularly over stables where the vapour, arising from the horses put in warm, ascends to the ceiling, is immediately condensed and falls in large drops. This may be avoided by firring out the ceiling, or laying the flat upon joists, and lathing and plastering the underside.

Tombs and monuments, with a variety of cinereal urns, are among the other objects of art, Mr. Austin being seemingly as desirous to provide for his dead customers as for his living ones. Many of these memorials of the dead are well adapted to produce an effect in those excellent establishments, the cemeteries, which are now being formed in all parts of the neighbourhood of London. I hope the day is not far distant when that disgusting and unnatural custom of burying in towns will be entirely dispensed with, as many of the churchyards have been proved to emit a vapour destructive to animal life, and to be the cause of much disease in densely peopled neighbourhoods, they are moreover most distasteful in their appearance, having their monuments and head and foot stones jumbled up together in heedless confusion. An English church-yard which ought to be the pride of the parish, particularly of the clergy, is mostly a jumble of broken stones, stiff graceless ledgers, and heaps of dirt, the whole in a miserably ragged condition disgraceful to a civilized nation.

There are several other subjects, figures from the antique, among which may be found a large assembly of gods and goddesses, animals, from the colossal lion to the petty lap dog—the famous dog of Alcibiades and the Florentine boar, standing most conspicuously—also many sphinxes and animals after Egyptian and Greek authorities; sun-dials and pedestals—the globe sun-dial is particularly interesting. But for space and time many more articles might be enumerated. I must now conclude, having been somewhat lengthy in my notice of this composition, with a view of forwarding its general introduction in place of stone, where economy is desirable, as it is capable of great variety of form and use.

For the purpose of illustrating this paper, I have through the kindness of Messrs. Austin and Seeley, selected several wood engravings from their book of designs, all of which are from specimens already executed.

[We hail with pleasure the renewal of our old correspondent's interesting papers, and will gladly second him in his laudable endeavour to serve the meritorious class he so warmly advocates.]—Editor.

"WESLEYAN CENTENARY HALL AND MISSION-HOUSE."

Letters of no mean size, affixed to the large, and, since its recent modifications, handsome building, which has attracted so much of the attention of the frequenters of Bishopsgate Street, thus announce to the public the new appropriation of the heretofore well-known City of London Tavern. The street front is of course the part most embellished, and with this perhaps the best has been done that it admitted of, and certainly a noble effect is produced, notwithstanding many disadvantages: for the old front being left standing, and the new being only an encasement of it, but little room for invention was afforded. The design is a Corinthian order, of four columns and two side pilasters, on a rather high basement: the four columns being surmounted by a well-proportioned pediment. The columns, which, of course, form the chief feature, are both bold and elegant, and have a very graceful outline: some persons might prefer them without the fluting, but we are inclined to think, that plain attached shafts at that height, would look heavier and less effective. The caps are about the best we remember to have seen, the volutes have a very graceful contour, and the leaves are bold and well relieved, and the whole of the sculpture, of which there is a good proportion, is executed with skill and decision. We are glad to see, from this instance amongst others, that enriched mouldings are again coming into use. The architect, whether from necessity or choice, has preserved all the original openings, and those in the ground floor, having been arched, are so still. This, though it gives the basement a character not quite in accordance with the Greek order above, yet produces a playfulness of line that, in our mind, greatly mitigates the defect, which, to the sticklers for antique precedent, will no doubt be serious: whilst, to another class, in which we may include ourselves, the adoption of the Greek, instead of the Roman or Italian style, will be a still greater offence. For we doubt if the delicacy of Grecian architecture can ever be made to accord with our climate and materials. The columns are somewhat close for their size, and the window dressings are consequently cramped: but this is rather the fault of the old building than of the new, and to the same cause it may be attributed that the parts are in better proportion than the whole. The breadth of effect would have been greatly increased by substituting columns for the two pilasters at the sides, but we presume they would have projected too far beyond the adjoining houses: a difficulty that must always occur in the streets of London, where houses jostle each other like persons in a crowd. With allowance for these defects, we should not do justice to the author (Mr. Pocock, architect,) if we did not state our honest opinion, that without attempting novelties, he has done the most his circumstances and style admitted.

The ceiling of the loggia is pannelled, and supported by four Doric columns fluted two thirds down. The rest of the interior, though handsome and substantial, is as plain in its architecture as at all accords with the magnitude of the structure and the elegance of the façade.

The general idea of the plan is perhaps the best part of the whole. Directly opposite the entrance gates of the loggia are the doors of the vestibule, and opposite these the doors of the hall, where a handsome flight of stone steps, with ornamental iron balusters, conduct to the corridor running straight forward, by the foot of an elegant circular staircase, to the anteroom of the secretary's office, so that the door of this anteroom is at the end of an avenue which continues in a straight line from it to the front entrance, each being visible from the other at a distance of more than a hundred feet. Rooms for other officers are provided directly over these, and are approached by the circular staircase before mentioned. Spacious offices for the transaction of the greater part of the business, are provided on each side of the outer hall, while those functionaries who require greater quiet, are provided for at the back part of the building. The flight of steps first mentioned, with the return flights leading to the Committee Room and the Library on the one pair of the front, occupy the lower part of a large covered area, from which light is obtained for the several apartments around. The workmen were still employed in the old Ball room when we were there, but, we understood, only in repairing and cleaning it, as it is to undergo no alterations, but to be fitted up with a platform and benches, and to be called "The Centenary Hall."

EPISODES OF PLAN.

(Continued from page 199.)

Whether intended for sideboard alcove, or other specific purpose, Recesses may be divided into *Simple* and *Compound;* and even those belonging to the first class admit of very great variety, exclusively of that which arises from embellishment. In their *plan,* for instance, they may be rectangular, or curved (and if curved either segmental or semicircular), or polygonal. In their *elevation,* towards the room, they may be arched or otherwise, with or without columns, &c. In *section,* they may be of the same height as the room itself; or *depressed* (that is lower); or *raised* (loftier); and if arched, in elevation, and curved or polygonal in plan may be covered by a *conch* or semidome. Neither is this all, since even this class may be subdivided into *Blind* and *Lighted* recesses. In the latter case various picturesque effects may be obtained according to the mode in which the light is admitted, which, however, should be so managed that the windows themselves are not visible, or else the recess assumes a different character, and becomes only a bay-window of the usual description, except it be that the window itself would not occupy the whole of it.

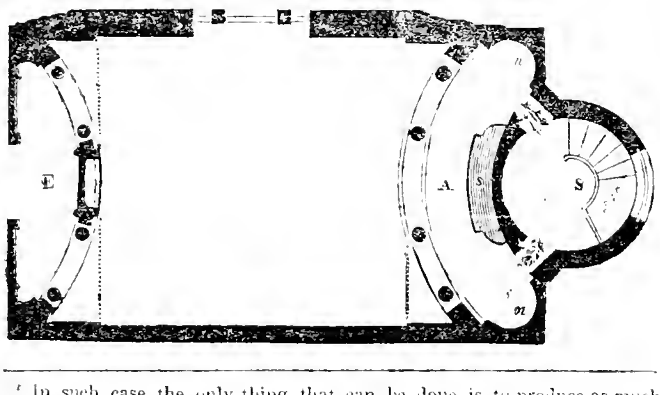
No instances occur to our recollection to which we can here refer at once as exemplifying some few at least of the forms and arrangements just pointed out: yet if this be so far inconvenient and unfortunate, it is also a tolerable proof that scarcely any thing at all has hitherto been done or even aimed at, as regards such features in internal plan; consequently that there is novelty of interior design in store for us, if we do but choose to adopt it, and to escape from that monotonous routine, and those *quotidian* forms to which architects now confine themselves.

Possibly there may be instances both in regard to recesses and other features of plan that might suit our purpose, and which may deserve to be brought forward by us as examples, were we but acquainted with them. Yet if they exist at all they are not generally known: there are no engravings of them in any publications, nor are any descriptive notices of them to be met with. To say the truth, peculiarities in design, of the kind here alluded to, are almost the very last which those who give us descriptions of buildings think of speaking of at all. Which, however, is the less to be wondered at, because architects themselves are, far more frequently than not, apt to pass them over in silence, even though such parts may happen to have cost them more thought and contrivance than all the rest of a design. In fact as regards interior domestic architecture, it very seldom happens that any thing more than two extreme points are taken into consideration: while nothing is aimed at in the general *laying out* of the plan, beyond what comfort, convenience, and facility of communication require,—nor is there always so much bestowed upon these as there might be; so also nothing amounting to architectural design is introduced into the separate rooms. Provided these last possess the negative merit of being satisfactory as to their dimensions and proportions, little besides is looked to for them, on the part of the architect. For all that gives them life and interest they are indebted to the decorator and upholsterer, or to the works of art which they may contain. In by very far the greater number of cases no attempt is made to obtain aught of decided architectural character, or of that kind of expression and effect, which may exist before such things as hangings and draperies, furniture and pictures are added. We are very far from despising or undervaluing such matters as these last; yet we certainly regret that attention should be too exclusively confined to them, when they are of subordinate importance, inasmuch as they admit of change and improvement at any time, whereas if architectural effect has been disregarded in the first instance, it is not always easy—sometimes scarcely possible to supply it afterwards, without considerably altering the building itself, and breaking up the original plan. On this account therefore it is highly important that the design should be carefully considered and strictly scrutinized in order to ascertain whether besides being satisfactory as regards convenience, and the required accommodation, it also provides a good deal of architectural effect throughout the various parts of it. Undoubtedly the present system has its conveniences: it spares a great deal of trouble—that is, of study and thought to the architect: but then it also cuts off the opportunity of displaying talent and invention upon a class of subjects, where, if allowed to be exercised, they would have free scope.

One obvious source of variety in plan, is to break the sameness of the quadrangular forms of rooms, by some kind of alcove or deep recess, constituting a distinct compartment, and further conveying the idea of extension, so much space being apparently added to what would else be the limits of the room, even although it should in fact be purposely taken from it in making the plan. Independently of all other effect such parts are almost sure to produce a good deal of pictorial expression in the ensemble of an apartment, by the effect of light and shade attending them. They may also be made to contribute very much to the air of habitableness and comfort; as many articles of furniture, or for mere ornament, may be arranged within such embayed compartments without at all crowding up or interfering with the rest of a room. Cabinets, stands for bijouterie, book-cases, ottomans, flower-stands, and other things of that kind, may there be tastefully disposed, so as to be at hand, and so as to form a striking and pleasing group of objects, and produce a certain degree of contrast as it were: not that contrast is indispensable, or indeed, in every case, adviseable. How far it is so, or the contrary, must depend upon the circumstances of the individual design, which cannot be prejudged according to any general rules, or directions.

Much may be made of an alcove or deeply embayed recess in a room, let the style of architecture adopted be what it may; and in any application of the Gothic something of the kind becomes requisite, in order to give character, particularly in a mere four-sided room, without either bay-window or any breaks in the walls.* In a room of the kind already built, or where the plan itself will not admit of a recess being formed, without interfering with some other room, or else occasioning some other difficulty, the appearance at least may be obtained by sinking a shallow arch-headed compartment on one of the sides, and decorating it with panelling and tracery filled in with pieces of mirror, so as to resemble an open-work screen. There is another point as regards Alcoves and Recesses, not yet mentioned, but which deserves to be considered, although it is one that does not admit of any positive instructions respecting it being laid down. We mean the relative size of the alcove in comparison with that of the room itself, and also the size of the opening which unites them. Independently of every thing else, here alone almost endless diversity may take place. Much also will depend upon the situation of such a recess, and whether there be only a single one, or more in the same apartment.

For want of positive examples, much of what we have hitherto said, may have been thought vague and obscure, and so far—if not otherwise—unsatisfactory. We now proceed, therefore, to give, as one of our Episodes, a plan for a Dining Room, having a rather spacious sideboard-alcove, communicating with which is a staircase exclusively for the attendants, and for serving up dinner;—the convenience of which is so obvious, that it is unnecessary to point it out.



* In such case the only thing that can be done is to produce as much effect as possible by means of the fittings-up and furniture, into which the spirit of the style must be carefully infused: or if not it is better to get rid at once of *every* indication of the style in such a room, concealing the upper part of the windows, as much as possible by draperies, should there be arched compartments of any kind in the heads of those apertures.

It will be evident at first sight that we do not offer this as one of the simplest arrangements of the kind, because it may in some respect be termed rather complex, and is, besides, very remarkable—some will, doubtless, say exceedingly capricious—for the form given to the ends of the room, those elevations being not only curved, but convex in plan. Should it be asked of us why we have chosen to bring forward so very unusual a circumstance, such question ought to suggest its own answer. Whether such novelty in the plan be judicious,—whether concave instead of convex ends would not be greatly better, is what the reader must determine for himself. But as it was our intention to give an instance of an alcove curved convexly towards the room, it is pretty evident that by making it otherwise than it is, we should have defeated our purpose.

Of the effect attending such peculiarity in the design, most of our readers, we presume, will have no difficulty—in judging from the plan, —that is as far as plan alone is concerned, independently of the mode in which it may be filled up. We ourselves are persuaded the effect would be pleasing, as well as strikingly novel. Owing to its colonnade being curved convexly, both that and the Alcove, A, itself, are brought forward more conspicuously. The opposite end of the room is similar in its general elevation, except that the middle intercolumn is filled up by a pier containing the fire-place, whereby the space E, or entrance alcove, serves as a kind of lobby (though not an enclosed one) to the room, and the chimney pier as a screen before the door, facing which last, there might be a blank door filled with a mirror, so as to give the effect of greater space on first entering. In this case the Dining-room is supposed to communicate immediately with the vestibule, consequently some kind of screen, (where one can be obtained, that shall rather aid than at all prejudice the architecture of the apartment) is desirable. But should the Dining-room be preceded by an Ante-room, it then becomes a question whether it would not be adviseable to alter that part of the plan, placing the chimney-piece opposite the window, and making the colonnade at E precisely similar to that at A. Owing to their bowing out towards the room, those colonnades or end elevations, certainly abridge it in some degree, yet not at all more than the plan will very well bear. While the space itself is in some measure reduced, the appearance of spaciousness is kept up. It is true such loss of space as is here occasioned at the angles of the room, can very seldom be afforded; but then, neither do we recommend a plan of the kind where it would be quite out of character with the rest of the house.

With respect to the alcove A, we have little to remark, except that the doors are so placed that when opened by the servants nothing can be seen of the staircase S. Should the sideboard *s* be insufficient, there might also be lesser ones in the two recesses *n n*, which if not required for that purpose, might have candelabra placed in them. Without at all altering the lower part or floor plan, an entirely different idea might be adopted for the upper portion at about the height of seven or eight feet, breaking through the wall above the sideboard *s*, so as to admit a view into the circular space over S, which would then become a small rotunda or upper recess, seen beyond the other. In such case there would of course be a ceiling between it and the staircase beneath. This recess would be domed, and have an eye or skylight, which should be filled with warm-tinted glass, so as to diffuse a sunny glow both over that upper recess and the alcove itself, and thereby greatly enhance the effect of the whole of that compartment as seen through the columns. The same effect might be preserved of an evening (before which a dining-room, if reserved exclusively for the purpose of one, is seldom used) by lighting it with gas on the outside of the skylight. We will further suppose this recess to be occupied by a statue (a mere cast) placed in the centre, and elevated upon a pedestal of such height that the whole of the figure would be visible from the middle of the room, if not nearer. An elevated recess of this description, might be made to answer the purpose of a music gallery, when one is required. We need not enter into further explanation or remark, as we have said enough to show what variations this plan admits of, accordingly as the section raised upon it is treated.

By no means do we pretend to say that the above Episode can be introduced into every or any plan; most certainly not. It seems best adapted for the rear of a house, in continuation of the ground floor; and supposing it so situated, and to have no other room above it, the apartment could be lighted by a lantern: that however must depend upon circumstances of locality, and whether sufficient light could be obtained from a side window according to the plan.

(To be continued.)

ON THE ARCHITECTURE OF WISBY IN THE ISLAND OF GOTHLAND, IN THE BALTIC SEA.

By John White, Esq., Architect.

Read at the Royal Institute of British Architects; March 8, 1841.

The perusal of the passages in Mr. Laing's Tour in Sweden which relate to the architecture of the city of Wisby,* have induced me to make the following observations as to the origin of that mode of the construction of edifices commonly called Gothic, and to consider the existing remains of that city, for which purpose I have availed myself of some northern connexions in obtaining some further information beyond what is already before the British Institute, and feeling that Mr. Laing has much advanced the knowledge of architectural antiquity by having recommended to the attention of the public, these very early, if not the earliest, examples of Gothic construction, I submit the following remarks.

The well known observation of Sir Christopher Wren (Parentalia, page 306,) "that what we now vulgarly call the Gothic, ought properly and truly to be named the Saracenic architecture refined by the Christians, which first of all began in the East after the fall of the Greek empire, by the prodigious success of those people that adhered to Mahomet's doctrine, who out of zeal to their religion, built mosques, caravansaras and sepulchres wherever they came," is to be opposed by examining the structures of the 11th century in those parts of Europe, especially the northern, where the Saracens never came, and this I trust will be manifest, independently of other proofs, from the examination of the architecture of the remains of those churches of Wisby so referred to by Mr. Laing, which are herewith communicated so far as the drawings of them are published.

The birth of Mahomet was in the year 569, and the conquests of the Saracens followed with rapidity the commencement of the 7th century, when the Saxon style of building is supposed to have been, in the northern portion of Europe at least, the prevailing form: of this, however, in England, we have few examples; Stukeley Church in Buckinghamshire, has been quoted by most writers as the most ancient and perfect example of the pure Saxon: it has certainly nothing Saracenic about it, excepting that all the arches are of a circular character, in common with the Roman and Saracenic, whereas what is denominated the gothic arch is universally of two or more centres describing portions of circles meeting at a point.

It may, perhaps, assist the inquiry to refer to the periods of the northern irruptions and conquests, which are as follow:

Their power in Italy, England, &c.	Began A.D.	Ended A.D.
Goths of Scandinavia	250	382
Saxons	366	not ended
Ostro Goths	400	568
Visi Goths	462	711
Lombards	570	774
Danes	787	1069
Normans	1016	not ended

The buildings at Wisby are admitted to have been constructed at the following periods:

11th Century. Churches.	A.D.	12th Century. Churches.	A.D.
All Saints	1030	St. Hans	1130
Holy Ghost	1046	St. Catherine	1160
St. Lawrence	1046	St. Gertrude	1167
St. Drotten	1086	St. Maria	1190
St. Peter	1088		
St. Michael	1090		
St. Nicholas	1097		

Of the Christian religion the following orders were founded:

	A.D.
Knights Hospitalers	1100
Augustine Canons	1105
Cistertians	1128
Knights Templars	1146

The following extracts from Grose's Antiquities may further elucidate the subject. See preface, page 63.

(Stowe's words on the Cathedral of London.)

"In the year 1087 the church of Saint Paul's (in London) was burnt with fire, and therewith most part of the city, Mauricius, then Bishop, began therefore the new foundations of a new church of St. Paul, a work that men of that time judged would never have been finished, it was then so wonderful for length and breadth, as also the same were builded upon arches, or vaults of stone, for defence of fire, which was a manner of work before that time unknown to the people of this nation, and then brought from France, and the stone was fetched from Caen, in Normandy, &c.

This, doubtless, is that new kind of architecture the continuer of Bede (whose words Malmsbury hath taken up) intends, when, speaking of the Norman income, he saith, "You may observe every where, in villages, churches, and in cities and villages, monasteries, erected with a new kind of architecture."

And again, speaking doubtfully of the age of the eastern part of the choir of Canterbury, he adds, "I dare constantly and confidently deny it to be elder than the Norman conquest, because of the building it upon arches, a form of architecture, though in use with and among the Romans long before, yet, after their departure, not used here in England, till the Normans brought it over with them from France. (Sommer's Antiquities of Canterbury.)"

Grose further observes, page 65, (on Saxon architecture):

"This was the style of building practised all over Europe; and it continued to be used by the Normans after their arrival here, till the introduction of what is called Gothic, which was not till about the end of the reign of Henry the First, so that there seems little or no grounds for the distinction between the Saxon and Norman architecture. Indeed, it is said, that buildings of the latter were of larger dimensions, both in height and area, and they were constructed with a stone brought from Caen in Normandy, of which the workmen were particularly fond; but this was simply an alteration in the scale and materials, and not in the manner of the building. The ancient part of our cathedrals are of this early Norman work."

That building was carried on in northern countries. Jonas Ramus states, in Norwegia Antiqua et Ethnica, pages 89 and 90:

That Dronthiem was built by Olave Tryggo, who became king of Norway, A.D. 996, and Bergen was built by Olave Harald Kyrre, who completed the Cathedral of Dronthiem began by Magnus the Good and his father. Olave Harald Kyrre was buried at Dronthiem, A.D. 1093. Magnus the Good died 1047.

Roger de Montgomery built Ludlow Castle after the Norman Conquest. In the enceint there existed a circular entrance to a chapel now destroyed; this circular entrance has considerable resemblance to that of the Temple Church in London. The drawings of Ludlow Castle made in 1774, show this building, and I have made a drawing of the plan of the Wisby Churches to the same scale as that of the Temple Church, in order that their dimensions may be compared.

The period of the introduction of arches described with more than one centre, is the matter of doubt; but it can hardly be conceived that a general appellation should be used without any foundation. The Gothic monarchy in Spain was destroyed in the beginning of the 8th century by the Saracens, and of the many buildings erected by them, the arches are all of a circular character, not concentric, but of more than a semi-circular form in the void.

The Cathedral of Barcelona was began in 1299.
That of Tarragona about - - 1200.

The monastery of Poblet, which in the interior much resembles the Wisby churches, in 1149.

It is not impossible that at the time the city of Wisby flourished, it had overland communication with India, as the troubles of the Eastern Roman Empire rendered the Mediterranean and its territories unsafe for merchandise, and as there exist in India many buildings constructed with arches even of four centres, it is possible that the Gothic arch may thence be derived, yet the Indian arches resemble more the vaultings of the Tudor style, and the most perfect of them are as late in the reign of Schah Abbas, who died in 1629.

Bishop Warburton, as quoted by Grose, says, our Norman works had a very different original from Saxon builders, who took their ideas from the buildings of the Holy Land, for when the Goths conquered Spain, they struck out a new species of architecture unknown to Greece or Rome, upon original principles, and ideas much nobler than what had given birth even to classical magnificence.

It is difficult to reconcile the style of our finest cathedrals as to their internal ranges of coupled columns with the groves of northern countries, because the fir seldom assumes, though the planted elm does, the general character of ribbed arches, but there is a natural progression of form proceeding from a repetition of the squares or round column to the octagonal, and afterwards to the coupled column, and the ribbed arches springing from the octagonal exist in the beautiful remains of St. Catherine's church at Wisby.

* Pages 304, &c. printed by Longman and Co. 1839.

In the bridge of Martorell in Spain, there are arches both of the semicircular and the pointed form. From the drawing in De la Borde's work it appears that the gothic arch (which is of 133 French feet span) is an enlargement of the water way, for the stones of two circular arches where it exists, are remaining, and exhibit the ancient work which was probably Roman. The arch is from the highest part of the soffit to the water 70 French feet. De la Borde does not say when this arch was constructed, but its magnitude renders the time of its being built a matter of interest in a question as to the origin of its form, for it would be wonderful if the Saracens had employed this mode of building, de novo, when an arch of less elevation would have better answered the purpose of a public way, and their Arabian or even Moorish origin was not likely to lead them to construct bridges of great span and height over the water way, there being little necessity for such edifices in their own country.

The first crusade was subsequent to the Council of Clermont in 1095, and it was at this council that the banner of the cross was assumed, from this assumption of the form of the Latin cross, it is probable that the plan of most of our cathedrals was adopted. None of the churches of Wisby have this shape, although there exist the repeated pillars, arches, and groins. The most ancient churches, viz. the church of Stukeley, that at Cambridge, and those of Northampton and the Temple, with the chapel at Ludlow, are totally different.

When the slender pillars were used it became necessary to employ the buttress, Mr. Samuel Ware* has successfully shown their importance, there is little appearance of their employment in the buildings of Wisby, where the pillars are of greater bulk and better calculated to support stone vaulted roofs. Stone groins certainly existed in this country at an early period, but they are confined to the crypts, and particular parts of buildings. The church of Stukeley does not exhibit any appearance of a stone arch in the main part of the building which has a wooden roof, and the Temple church has a wooden roof both over the circular part and the body, both which roofs are extremely ancient, and verging into great decay, though of the finest oak.

It may be deserving of inquiry as to where the largest and most perfect groin exists, domes are of greater antiquity, perhaps the groin of Julian's palace at Paris is that best known in this part of Europe.

I will conclude these observations by referring to the correspondence which has taken place relative to the ruins of Wisby with Major Gerss of Stockholm, by which it will appear that for the sum of 80*l.* numerous drawings can be supplied. The printed documents which were procured by my son at Stockholm, accompany this paper, together with a translation of a short history of Gothland and Wisby, the general map of the country will exhibit the situation of the island and the city, and the appendices afford various authorities of its antiquity and destruction. The lithograph plan of the city of Wisby will show the situations of the various churches and Wisby Klingwalls. Parts 1 and 2 will exhibit the buildings which have formed the subject of an intended work, but which has not gone beyond these two portions of it. It is to be hoped that it will be continued and improved upon.

January 30, 1841.

* See his work, "A Treatise on the Properties of Arches and their Abutment Piers." By Samuel Ware, Architect: London, 1809.

A FEW OBSERVATIONS ON PALLADIO.

ADDRESSED TO MR. CROKER, &C. &C.

I had hoped to have pursued a train of thought upon Palladio and his school, without startling one critic into life. Like a young and cautious mariner, I ventured not far into the open sea, because I knew critics were afloat, and because I knew them armed with every classic weapon of attack. These gentlemen, like pirates grown old in their ugly warfare, are ever to be found on the ocean of taste, whilst, with weapons sharpened upon some old ruin, and with prejudice for a war cry, they hunt for every modest searcher after the beauties of Italian art. It was for this reason, perhaps, that a partiality for Palladio seldom tempted me to an invidious comparison; I merely admired a man of original daring, and left a crowd of copyists and purloiners from Athens and Rome to interpret at their pleasure.

A sail, however, is astern, bearing up the gallant Mr. Croker, who, with spy-glass in hand, finds my rigging defective or my vessel weak. His frown is on me for my late remarks upon Campbell and Palladio. He thinks, however, because I cited no examples to support my fancies, that the guns of defence are few, and so his face changes into smiles, and his laughing caution to surrounding friends is "risum teneatis!" Now this amusing merriment in the critic amuses me, and were it not for the singular attitude of his pen at the conclusion of his letter, I should have passed from his comment with a smile. Mr. Croker's pen is made to suspend itself in threatening shape over me, to alarm and intimidate my own. Perhaps, however, it may be that the awkward little feather which Mr. Croker handles, is conscious of its intended misappropriation, and very properly shocked at the injury it is likely to inflict upon the fame of Palladio, forsakes his hand. But why does the conscious sensitive thing hang over me? Perhaps to warn me of a future attack. Mr. Croker evidently imagines his quill an object of terror, and so makes no small effort to direct me to it; but upon close inspection I perceive the little creature too harmless to disturb, and too innocent to vex.

I do admire Palladio, and if my partiality is a passion, it is a passion more like sentiment than the passion of a childish instinct. I admire Palladio for his daring and originality, for his starting up in the midst of error, when art began to grow fanciful and trifling, for his care in shunning the evils of his time, and borrowing from the beauties of the past. To test Palladio too severely by the models of antiquity, is unfair and impossible, because the modification and change necessary to the structure destroy the parallel. To test, too, Palladio by the mean experiment of subordinate variations, is ungenerous, because Roman architecture itself, imposed with its parts, much more than it charmed by its minutiæ. Palladio's great achievement, too, was the adaptation of the orders to domestic habitations, in which antiquity became subservient, and in which the whole array of detail was subsidiary. One great reason why many condemn Palladio is, because he leads them occasionally into error, and too loosely scatters his decoration. Tell them of a palace or a church designed by him, and they will tell you of an incorrect member or a broken tympanum: or speak to them of originality, and they will shout for a precedent. The source of beauty, however, may have been misunderstood, and the elements of grandeur may have been mistaken. Beauty belongs to no particular form, but to the harmony of relations blending in that form; and the same principles which adjusted the lovely outlines of antiquity, may enter into the composition of larger and grander objects. Nature supplies such innumerable varieties of beauty, such apposite changes, that I wonder *some* cannot perceive the lesson she would teach. These few remarks, arising out of Mr. Croker's observations, are all I wish at present to offer. I have not gone coolly into a digest upon Palladio, because at present I have been alluded to merely in the language of general disagreement. My reflections are therefore mere generalities, but capable, I hope, of assuming a more connected form, should the objections of a critic assume a sober shape and demand it. I do not, however, allude to Mr. Croker so much, for his reflections are generally sound and liberal; I rather fancy before me, as I write, the enemies of Palladio's style to whom he addresses his "risum teneatis," and in whose judgment nothing but the antique can please.

April 13, 1841.

FREDERICK EAST.

ENGINEERING WORKS OF THE ANCIENTS, No. 4.

The last author from whom we took was Polybius, who lived B.C. 124, the one from whom we now select, Xenophon, preceded him in time, living 400 B.C.

PERSIAN ENGINEERING.

CANALS—TIGRIS—INUNDATION—IRRIGATION.

It is in those works which treat of Persia and Egypt that we find the most information as to engineering, for the Greeks, as we have before explained, from geographical position, having no considerable rivers, were not called upon to execute those long canals and large bridges which were of vital necessity to their eastern and southern neighbours. It is therefore in Asia and Africa that we must look for the schools of engineering, of which the practice has been transmitted to us through the Greeks and the Romans. When quoting from Herodotus we before mentioned the Persian canals, and we now take from Xenophon, commander of the Greek army, what he says on the subject in his work called the Expedition of Cyrus, or Retreat of the Ten Thousand: it being our purpose not to collect what has been said on each individual subject, but to abstract from each author seriatim his separate testimony, so as to form in these essays a kind of diplomatic collection or chartulary, from which the student may derive his own materials. Of the plain of Babylon, our author says,* that in it are four canals derived from the river Tigris; being each one hundred feet in breadth,

* Book I.

and deep enough for barges laden with corn to sail therein; they fall into the Euphrates, and are distant from one another one parasang, having bridges over them. With regard to the origin of these canals, Arrian differs from our author, as he says that the canals which run from one to the other are derived from the Euphrates and fall into the Tigris.—Strabo and Pliny confirm this, assigning as a reason for the construction of the canals, that they are cut to receive and distribute the increase of water arising from the melting of the spring snows.

Clearchus† whilst in the same district on his retreat was much embarrassed by meeting with canals and ditches full of water. Clearchus suspected that as this was not the season to water the country, that the king had ordered the waters to be let out to impede the Greeks on their march.

About a day's march from Babylon the Greeks made in two days a march from Babylon, eight parasangs and passed two canals, one upon a bridge, the other upon seven pontoons.—Xenophon again says that these canals were derived from the Tigris, and that from them ditches were cut that ran into the country, the first broad, then narrower, which at last ended in small water courses, such as were used in Greece to water a kind of grain called panic.

To the history of these canals we shall be able to derive many contributions when we come to the works of Strabo, Pliny, and Ammianus Marcellinus. The boats of the Babylonians, as described by Herodotus, were peculiarly adapted for the navigation of these canals. At present the canals are choked up.

BRIDGES.—PASSAGE OF RIVERS AND CANALS.—PHYSCUS.

In the course of the expedition and the retreat, the Greeks came to many broad rivers, which in general they passed by fording, or by crossing on rafts: near Babylon they were able to avail themselves of the bridges of which they mention several. On one occasion coming to the Tigris‡ they found the river very deep, when a Rhodian proposed the following plan. "I shall want," said he, "two thousand leather bags—I see here great numbers of sheep, goats, oxen, and asses: if these are flayed, and their skins blown, we may easily pass the river with them.—I shall also want the girths belonging to the sumpter horses: with these I will fasten the bags to one another, and hanging stones to them, let them down into the water instead of anchors, then tie up the bags at both ends, and when they are upon the water, lay fascines upon them, and cover them with earth. Every bag will bear up two men, and the fascines and earth will prevent them from slipping." The generals considered this proposition ingenious, but were afterwards enabled to get out of their difficulties another way.

In the First Book bridges are mentioned over four canals near Babylon, each a hundred feet long: in the Second Book we have a reference to another; and in the same book we find it stated that over the river Physcus, one hundred feet broad, a bridge was placed communicating with a large and populous city called Opis. When Clearchus came among the flooded canals, he passed them by temporary bridges made of palm trees.

WALL OF MEDIA.

In the Second Book we have mention of the Wall of Media, which was built with burned bricks laid in bitumen: being twenty feet in thickness, one hundred feet in height, and as it was said twenty parasangs in length, and not far from Babylon.

CITIES AND FORTS.—WALLS.—LARISSA.—MESPILA.

Larissa or Resen is described in the Third Book as a large uninhabited city near the Tigris, anciently inhabited by the Medes, the walls of which were five-and-twenty feet in breadth, one hundred in height, and two parasangs in circuit; all built with brick, except the plinth, which was of stone, and twenty feet high. One day's march from thence the Greeks came to a large uninhabited castle near a town, called Mespila, formerly inhabited also by the Medes. The plinth of the wall was built of polished stone full of shells, being fifty feet in breadth, and as many in height. Upon this stood a brick wall fifty feet also in breadth, one hundred in height, and six parasangs in circuit.

PYRAMID OF LARISSA.

Close to the city of Larissa, says Xenophon, stands a pyramid of stone, one hundred feet square, and two hundred high, which seems to have been hollow.

GREEKS.

The observations of Xenophon as to Greek engineering we extract from his history of the affairs of Greece. In his Expedition of Cyrus however he alludes to the mole of the harbour of Byzantium, and to his forcing the Ionian Greeks to repair the roads through their cities preparatory to the march of his army.

QUARRIES OF THE PIRÆUS.

The quarries of the Piræus (Book 1st,) were in Xenophon's time wrought by Syracusan prisoners, who were confined there, and who made their escape by digging themselves a passage through the rock.

CAPTURE OF MANTINEA.

In the course of the Peloponnesian war (Book 5th) Mantinea was captured by the Spartans under Agesipolis. Besides the usual works of digging a trench, and constructing a wall, he dammed up the river, which was a large one, running through the city. The channel being thus dammed up, the water swelled above the foundations of the houses and of the city walls. The lower brickwork (being probably of raw bricks) was soon rotted by the wet, and shrank under the upper buildings, by which means the city walls cracked, and afterwards were ready to tumble. For some time they underpropped them with timber, and made use of all their art to keep them from falling. The Mantinians ultimately consented to demolish their walls.

BRIDGE OF SELLASIA.

A bridge is mentioned in the Sixth Book, at Sellasia leading to Sparta, but no description is given of it.

DOCKS OF GYTHEUM.

The docks of the Spartans (Book 6th,) were at Gytheum.

PUBLIC INNS AT ATHENS—SHOPS, &c.

In his pamphlet on the revenue of Athens, Xenophon alludes to the public inns for the use of strangers, he also recommends the building of greater numbers of shops, warehouses and exchanges for common retailers, relying upon it as a good means of revenue.

REPAIRING PUBLIC BUILDINGS BY CONTRACT.

Xenophon also in this pamphlet slightly alludes to the custom which the Greeks had of letting out the building and repair of their temples to private undertakers also mentioned by Athenæus and Herodotus, B. 5, C. 62.

† Book 2nd. ‡ Book 3rd.

DOUBLE OFFSET PLOTTING SCALE.

The Silver Medal was presented by the Society of Arts to Mr. James G. Austin, 36, Grafton Street, Gower Street, for his Offset Plotting Scale for the use of Civil Engineers and Surveyors.

The Double Offset Plotting Scale consists of two perfectly parallel graduated scales, whose distance is equal to the length of the offset scale which runs on rollers between them. The parallel scales and the offset scale are graduated to suit the views of the user. The pieces connecting the ends of the double scale are hollowed out to receive weights, armed with points to enter the paper, which hold the instrument in its place, and prevent its being shifted while in use; and from the centre of each of these connecting pieces projects an index; the points of these indices and the zero of the offset scale being always in the same straight line, which is, of course, the line from which the offsets are to be measured.

BRIDGE OF THE HOLY TRINITY.

In constructing the curve of the arches of the bridge of the Holy Trinity, according to the geometrical solution given in the last number of the Journal, I found the arcs EH, HH, make an angle at H, in consequence of the centres GI not being in a right line with the point of intersection H. This fault must have been overlooked by the author of the paper, and I take the liberty of thus troubling thee in order that the error may be corrected. May I also ask what advantage an arch upon this construction would have over a semi-elliptical one of the same versed sine (besides the simplicity of striking out the curve)?

I am, respectfully,
INEXPERTUS LOQUENDI.

Neath, 4th month, 12th day, 1841.

IRON STEAM VESSELS,

Built by Messrs. Wm. Fairbairn, and Co., of Millwall, London.

Date.	Name.	No.	Tonnage.	Horse Power.	Length on Deck.	Beam.	Depth of Hold.	Remarks.
					ft. in.	ft. in.	ft. in.	
1830	Lord Dundas, Twin boat.	1	41	18	68 0	11 6	4 0	An experimental boat, built for the Forth and Clyde Canal Company, with an engine on the locomotive principle, and light draught of water.
1831	2d Lord Dundas	2	44	20	68 0	12 0	6 6	This is the first iron boat that ever went to sea, as she made the voyage from Liverpool to Glasgow. She was built for the Forth and Clyde Canal Company with paddle-wheels on the quarters, and was employed as a coasting trader to Grangemouth, and the adjoining ports.
1831-2	Manchester	3	70	30	70 0	15 0	8 0	This was the second vessel that made a sea voyage; she was out in a severe gale in the month of February, 1832, and behaved to the admiration of all on board.
1832	Canal Boat	4	$10\frac{1}{2}$	—	60 0	6 0	4 0	
1833	La Reine de Belge	5	64	24	73 0	14 0	6 6	Built for a company at Bruges, and made the voyage from Liverpool to Ostend, and is now employed on the Scheldt.
1833	Minerva	6	108	40	98 0	15 6	7 0	Built in sections for the Lake of Zurich in Switzerland, sent in parts from Manchester to Hull, and there reconstructed, and made the voyage from Yarmouth to Rotterdam in 33 hours; steamed up the Rhine to the falls, and then taken to pieces, and carried overland; and again reconstructed on the banks of the Lake.
1834	Railway	7	164	50	110 0	18 6	8 0	Two packet boats from Selby to Hull, each drawing about 3ft. 3in. water. These boats have been plying with great success for the last 5 years upon the Humber; are still perfect, and quite free from oxidation.
1835	L'Hirondelle	8	171	60	115 0	13 0	8 0	
1836	Ludwig	9	$176\frac{33}{94}$	40	120 0	17 0	8 0	Built for the Lake of Constance, and sent out in sections. She has proved a good and fast boat. This vessel was the first built at the new premises at Millwall.
1836	Little Dreadnought	10	14	—	—	—	—	Built after the model of an East Indiaman's long boat, and has been in constant service on the river, carrying iron and other goods, and heavy castings, for 4 years, without having required the slightest repairs. On one occasion she was between two heavy ships in a tier when it broke from its moorings, and the whole of the vessels swung across the river. She was exposed without thwarts to the whole of the pressure consequent on such an accident, but was not in the slightest degree injured.
1837	Sirius	11	$249\frac{26}{94}$	70	175 0	17 1	7 10	Built for the Rhone. The engines were high pressure, with locomotive tubular boilers. Her speed was 12 miles an hour, and she drew, when light, 2ft. 6in. She was very stable, and made the passage to Marseilles partly under canvass. She was out in a very heavy gale in the Bay of Biscay, and behaved well, and on her arrival at Marseilles, was as dry as when she left the river Thames, not having made the least water, or having sprung in the least degree.
1838	Ladoga	12	$215\frac{53}{94}$	80	140 0	18 0	9 0	Swift and strong boat, used as a messenger packet by the Russian Government. Draught of water 3ft. 8in.
1838	Nevka	13	$231\frac{34}{94}$	70	150 3	18 0	9 6	Private yacht for the imperial family of Russia. Fast, strong, and substantial, and fitted with very handsome and massive cabin furnishings, schooner-rigged, and remarkably fast under canvass. She proved herself a good sea boat on her passage across the North Sea, where she encountered some severe gales, drawing 3ft. 10in. of water. For particulars see Weale's Appendix to Tredgold, parts A and B, where all the details are published.
1838	Prussian Eagle	14	$100\frac{41}{94}$	50	118 6	14 0	6 6	Built for the Upper Elbe, for the Royal Maritime Society of Berlin, with a draught of water of 28 inches. In her passage across the North Sea, she was caught in the gales of this year, and after having been out for three days she was pooped, and was ultimately lost off the coast of Ameland, having a fishing-smack in company.
1839	Concordia	15	$118\frac{43}{94}$	26	112 3	15 0	8 3	Built for the Upper Rhine, and sent out in sections. She has proved a fast and good boat; draught of water 3ft. 6in.
1839 and 1840	Two steamers	16 17	334	80	125 0	24 0	9 0	Built for the Hon. East India Company for Bombay, and sent out in sections.
	Four steamers	18 to 21	334	80	125 0	24 0	9 0 and 5 0	Built for the Hon. East India Company, and sent in sections to Calcutta.
	Four accommodation boats.	22 to 25	334	—	125 0	24 0	5 0	Built for the Hon. East India Company, and sent as above.
1839	The Shell	26	$111\frac{71}{94}$	30	102 6	15 3	4 0	Steam barge for the Thames up to Oxford, passing through the locks. She has two paddle-wheels on the quarters, and goes fast with a cargo of 50 tons on a draught of 3ft. 3in.
1839	Woronzow Pradpriatie	27 } 28 }	$91\frac{2}{94}$	40	81 0	16 0	8 0	Built for the "Russian Government" for the Black Sea, for the purpose of towing lighters at the mouth of the rivers, and confined in draught of water to 3ft. 4in. They proved themselves on the passage out to be perfectly safe as sea boats, though unable to beat to windward, and in the Black Sea, they encountered the very severe gales of November and December of this year. One of them was on shore, but was lightened, and afterwards got off uninjured and proceeded, and on arriving at Sevastopol got up steam, and towed a large Russian steamer into the harbour.

Date.	Name.	No.	Tonnage.	Horse Power.	Length on Deck.	Beam.	Depth of Hold.	Remarks.
					ft. in.	ft. in.	ft. in.	
1839	Dolphin	29	$106\frac{59}{94}$	50	111 6	14 0	7 6	Built for the "Royal Maritime Society" of Berlin for the Upper Elbe, Havel and Spree to Berlin. The dimensions were regulated by some locks and bridges. She is of a very full model to save draught of water, which was limited to 2ft. 2in. She is partly used as a tug boat for towing the lighters of the country.
1840	Coquette	30	$163\frac{34}{94}$	50	150 0	15 0	8 0	Fast and strong built. She is very stable, and her speed is fully equal to 13 miles an hour. Her great length gives great accommodation for tonnage, and if speed and accommodation are considered conjointly, the results are perhaps the best yet obtained by any vessel.
1840	Iron Duke	31	$109\frac{73}{94}$	24	104 6	15 0	7 9	For the river at Demerara, as a steam-barge to carry 40 hogsheads of sugar, stowed in the holds, on a draught of 3ft. 3in. She carried this cargo at a speed of 7 miles an hour, and made the passage across the Atlantic in safety on this draught of water, being fitted with lee-boards like the Yorkshire billy buoys.
1840	Telegraph	32	$206\frac{45}{94}$	45	136 0	18 0	8 3	Built for the Weser and adjoining coasts, and gives good results, being a strong and substantial boat. The draught of water was confined to 2ft. 8in. She made the passage from Gravesend to Bremenhafen in 46 hours.
1840	Steamer	33	$38\frac{65}{94}$	14	81 0	10 0	7 6 and 4 6	Built for one of the lakes in the north of Italy, and sent out in sections.
1840	Rose Thistle	34 } 36 }	$305\frac{54}{94}$	100	153 6	20 6	11 6	Built for Sydney in every respect as sea-going steamers of the first class. They are built of a very fine model and are very fast. Their speed in the river when light was proved to be 13 miles an hour. They carry 60 tons of cargo on a draught of 7 feet of water.
1840	Steam dredge	35	54	6	65 0	14 0	4 0	Built for clearing out the Fossdyke Navigation with bucket frames to work on either side, and deepen the sides of the canal. The draught of water is 2ft. 3in., and she was towed round the coast of Lincolnshire, by a steamer without injury in the month of January.
1840	Steam ferry boat	37	$25\frac{59}{94}$	12	66 6	9 0	7 0 and 4 6	Built for Calcutta for the Hoogly, and sent out in sections, with oscillating engines. The draught of water will not exceed 18 inches when light.
1840	Canal boat	38	$11\frac{74}{94}$	—	65 0	6 0	3 2	Adapted for swift canal navigation by horses, at a speed of 10 miles an hour.
1840	Steam barge	39	$31\frac{67}{94}$		78 9	9 0	5 0	Built for an experimental barge.
1841	Yarra Yarra	40	$93\frac{40}{94}$	30	96 0	14 6	7 10	Built for Port Phillip, New South Wales, and sent out in sections all complete.
1841	Juno	41	$135\frac{40}{94}$	—	82 3	19 6	12 0	Building for the trade between London and Hull. To be rigged as a schooner.
1841	Barge	42	$68\frac{38}{94}$	48 men	60 0	16 0	4 0	Building for a floating fire-engine, and fitted with a pair of paddle-wheels. The engines are worked by cranked handles by 48 men, and arrangement is made by which they can be thrown out of gear, and the paddle-wheels can be connected and set in motion, that the barge may be easily removed to wherever it may be required.
1841	Steamer	43	$254\frac{57}{94}$	80	150 3	19 0	10 0	Building for the Royal Danish Board of Admiralty, and intended chiefly for a private yacht for the Royal family of Denmark.

The extensive use of iron steam vessels makes any information upon the subject most valuable, and we therefore feel highly indebted to Messrs. Fairbairn for their liberality in furnishing us with the preceding notes. Being engaged in this manufacture to such an extent, the results of Messrs. Fairbairn's experience are valuable, and we trust that their example will enable us to obtain from other distinguished engineers such materials as will form an important record of the progress of this branch of engineering and marine architecture.

THE BOARD OF TRADE AND THE RAILWAYS BILL.

During the last month a good deal of time has been lost with the Easter recess, so that the committee to whom at Sir Robert Peel's wish was referred the consideration of the powers as to railways to be given to the Board of Trade was only able to meet in the beginning of the month, when for several days they were employed in hearing witnesses for and against the plans of the Board of Trade. The evidence of Mr. Brunel against the proposed interference is said to have had great influence upon the committee, and seriously to have annoyed Mr. Labouchere, but we regret to have heard it reported that a railway engineer of great eminence had taken a very different course, and had given his support in favour of the views of the Board of Trade, and against the profession. We sincerely hope that there may have been some mis-statement with regard to this latter circumstance, as we think that such a course at the present moment is likely to be of serious prejudice to the welfare of the profession. On the motion of Lord Granville Somerset a number of reports and returns relative to railways have been published, which are quite confirmatory of the worst surmises as to the conduct and intention of the Board, and its Commissioners. It is very true that much of the arrogance of the government functionaries is directed against the companies and directors, but it must not be supposed that they are the only parties threatened. On the contrary, the military engineers (for such we regret to say all the inspectors have been) give arbitrary opinions as to the use of blocks or chairs, the form and weight of rails and chairs, the construction of locomotives and carriages, the manufacture of axles and wheels, gradients, embankments, mode of working, and whatever else they can possibly interfere with. Nor is this all, for one of the party, with the accustomed hankering for meddling with private property, proposes to excise the locomotive engineers, as Major Pringle and his colleague did the marine engineers. It is suggested that to ensure the manufacture of axles of proper materials, the engineers and the assistants should at all times have access to every part of the works, and it needs scarcely to be presumed that this suggestion will be carried by the same power being claimed for the government officers, powers which it is known are useless as a protection, and useful only as an annoyance, for if there be a disposition to act wrongly no inspection of this kind avails, instances having occurred of fraudulent rails having been made under the very eyes of engineers. In the same spirit recommendations were made that stations should be shut up, and that locomotive engines should be licensed, a recommendation, which though to short-sighted men it may appear to the advantage of engineers is clearly the reverse, for it is sure to follow that under such restrictions the supply must be reduced.

The bill itself we have described, this appendix to it is a rich commentary on its spirit, dictated by ignorance, it is pregnant with quackery and oppression, and while its recommendations would be inoperative for any useful purpose, they would be abundantly effective for mischief, a delusion on the public and an injury to the profession. In the course of the last month all the railway companies have petitioned against it, not one engineer. We have done our duty, we have called —we call on the profession to petition and oppose, and we urge them to lose no time. Let them read Colonel Thomson's report, and imagine such a man as he excising their offices and their workshops, and then if they are not aroused, we do not imagine they ever will be.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXVI.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. It is consolatory to learn from the Licensers' *imprimatur*, that the "Fabbriche e Disegni di Andrea Palladio" do not contain any thing contrary to *la Santa Fede Cattolica!*—they might as well have assured us that Palladio was not the heathen divinity Pallas. Yet if the collection contain nothing against the holy Catholic faith, it contains much that is calculated to stagger any reasonable man's faith in criticism, and to shock his taste mortally, if he has any taste to be shocked at all. The very best of Palladio's designs are but very mediocre indeed, and some of them absolutely barbarous. His "Palace of Reason"—as Mrs. Cresy somewhat unreasonably calls it—is just execrable; his Teatro Olimpico, just damnable. And should it be said that this is mere sweeping condemnation, amounting to nothing, I reply that it is quite as good criticism as that in which the admirers of their incomparable Andrea deal in. The *onus probandi* lies with them; and if they are utterly unable to point out any of those beauties, graces, and excellences which they place so largely to the credit of their favourite, they have centainly no right to censure their opponents for being not more explicit. Should it further be thought by some of my readers that I am continually "harping upon" Palladio, my excuse is that I feel it necessary to do so, as long as others continue to babble their praises of him. When they choose to desist from their tedious iterations, I may give over mine; but I do not see why I should fling up the game, while they continue it.

II. Though few will give me credit for blushing at any time, I frequently do blush at the drivelling silliness one meets with in architectural writers—the more than anile twaddling to which they are addicted, for even the most twaddling old woman would hardly utter such stuff, unless, she happened to be disguised—in liquour.—"Facendosi addietro di sicolo in secolo," says one, "tracing back the art from age to age, we discover it to be almost contemporaneous with the origin of the human race." Wonderful discovery, truly! But still the tailors have in point of antiquity, superiority over architects, for Breeches-making is indisputably the oldest art upon record. Surely those who write such egregious balderdash must trust largely to the stultification of their readers. Writers on the art culinary are by far a more sensible race, abstaining from such asinine absurdities in which architectural ones are apt to indulge, and for which they ought to be made to bear a fool's cap as their crest.

III. It certainly is amusing enough to observe how excessively lax and licentious are some of those grave twaddling architectural puritans who lay so much stress upon proportions, as if they were absolutely articles of faith. People of that sort are absolutely scandalized at the idea of any alteration in the shape of a base or capital, or of making an entablature at all deeper or the contrary than usual; yet they are not the least shocked at seeing an entire ordinance thrown out of proportion by disproportionably wide intercolumns; nor have they any notion of regulating the entablature according to the distance between column and column, notwithstanding that it is obvious that if those intervals be unusually wide the entablature ought to be of lighter proportions than is else given to the order; and *vice versa*. For this reason, if for no other, the portico of the National Gallery ought to have had a bolder and richer cornice, the intercolumniation being pycnostyle, and consequently the supports numerous and the openings between them narrow. For the same reason, the pediment might very properly have been made deeper. Unfortunately, however, Wilkins was one of those people, who suffer themselves to be duped—or rather, who dupe themselves by words and names. His building was to be *Greek*—that was with him a *sine qua non*, to which other considerations were to give way. A Roman entablature or cornice was out of the question, not because it would not have harmonized with the columns, but because it might have been *called* Roman, and there might have been a sort of discord, not visible indeed, but *nominal*—of course a most offensive one, for it is well known that people in general judge of architecture as they do of pictures and of wines. Tell them that a picture is by Raphael or Corregio, and though it be ever so mediocre, they fall into raptures with it, at that word of command. Call gooseberry wine by its proper name, and people turn up their noses at it, yet dignify it by the style of champagne, and it becomes delicious. Under the sanction of Inigo Jones or any other celebrated body's name, the dullest design imaginable passes for a very fine thing, where one a thousand times better by some nobody, would hardly be looked at.—I was once equally amused and enlightened at the expense of an unfortunate critic who was a professed admirer—I might say venerator of Palladio. We were turning over a portfolio of loose architectural prints and drawings, among which there happened to be one or two to which I called his attention more particularly, at the same time instancing several egregious sins in them against good taste. After assenting to all my objections, he exclaimed "they are indeed very trumpery specimens of the Italian style: they have nothing of the *sana architettura*—of the gracefulness and happy *non so che* of the divine Palladio."—"The deuce they haven't!—why is it possible that you do not recognize them as the production of your divine Palladio himself?"—He looked—what shall I say, aghast?—no he looked as if he was actually going to jump down his own throat." The next time I saw him I said—"and the divine Palladio ——," on which he cut me short by crying out, with no lack of emphasis—"Palladio be damned!"

IV. For graphic power—for consummate mastery in the art of depicting to the eye by means of the pen alone the loveliest scenery, and conjuring up the most enchanting prospects—the most fascinating visions,—I hold George Robins to be the greatest genius this or any country has ever produced. Some of his advertisements are perfect cabinet pictures, finished up with unrivalled delicacy and grace, and replete with such felicity of imagination that every object—no matter what it may be in itself, is transmuted into beauty by the potent alchemy of his pen. As viewed through the medium of his poetic imagination, a snug suburban tenement with an acre of domain attached to it, becomes—I will not say "un pezzo di cielo," nor an absolute paradise, nor a *lot* from the Elysian Fields,—but certainly a fragment of Arcadia, a pastoral landscape fit for a scene in an opera—a fairy-land encompassed by the hedge that fences it out from ordinary, every-day nature—from the mere fields, the green grass and green trees, that may be seen anywhere else. From my soul I pity the dull creatures who can see nothing more in the great G. R.'s effusions than a mere auctioneer's advertisement; and I also pity those who toss from them the half sheet of the Times, exclaiming in a tone of disappointment, it is nothing but advertisements, when advertisements are in fact the very essence of a newspaper, and the rest but mere flummery and filling-up stuff, a farrago of twaddle political, fashionable, &c., dressed up in blustering phrases.

V. "I have seen Abbotsford," says T. H. C., the clever author of "A Descriptive Tour in Scotland,"—"and I hardly know whether I do not regret that I have done so. It is not the Abbotsford of my imagination, nor of the author's description. Where is the 'romance in lime and stone'?—Dwindled to a mere story. In the exterior of the dwelling there is no congruity, no massive nobleness. In the interior there is no space for ghosts to play at hide-and-seek. If there be a few odd holes and corners, they appear rather like small remnants of a scanty cloth that has been cut into a thrifty garment, than the 'ample room and verge enough' of true antiquity. Nothing is on a great scale. Ichabod—the glory is departed. In this as in other instances, *exaggerating describers have much to answer for*."—Mark you that, my dear George Robins!—"At their hands one demands an account of one's demolished hopes and scattered visions." If so, a good many dealers in description will have an awfully long and heavy score to settle with their readers. The best way for them to do so, would be to bring in a *per contra* account for so many manufactured visions of grandeur and beauty—not a trace of which is to be discovered in the objects themselves.

VI. A most outrageous sort of delicacy is affected by writers upon architecture who generally evade speaking of contemporary buildings, under the pretence of its being invidious to make any comments on the works of living architects. Such excuse is most flimsy: or if there be any thing in it at all, gross indeed must be the indelicacy of literary critics and reviewers who make the publications and writers of the day the subject of their comments, without the slightest sort of scruple or ceremony, and frequently with the greatest imaginable freedom. The excuse itself moreover, is not particularly complimentary to the living, inasmuch as it almost amounts to the declaration that silence on the part of criticism can alone save them and their works from the censures that honestly expressed opinion would inflict upon them. In itself, however, such silence is, I have no doubt, exceedingly convenient, for I suspect that those who avail themselves of it, have seldom any opinion of their own to express, but generally serve up to their readers second-hand *criticism*, got out of books.

A NEW SIGNAL LIGHT FOR RAILWAYS.

By Alan Stevenson, LL.B., Civil Engineer, Edinburgh.

(Read before the Society of Arts for Scotland, 22nd February, 1841.)

The numerous accidents, attended with fatal consequences, which have lately occurred on railways, have excited much alarm in the public mind, and the prevention of these casualties is unquestionably a matter of great importance. The object of this communication is, to point out one source of danger to which several of the late accidents may be attributed, and to suggest the means of its removal: and from the personal interest which all must have in the improvement of railway travelling, both as regards its speed, and, what is of much greater importance, its safety, I venture to hope that the following observations, although limited to one part of the subject, will not be found to have been unsuitably addressed to a society whose province it is to improve the useful arts.

One of the most imperfect parts of the railway system is undoubtedly the uncertainty of the night signals, and to this it is well known many of the most fatal of the accidents which have occurred must be traced. The great object of these signal lights is, to announce that the train has reached a certain point of its course, and to forewarn the engineman of his approach to a station, or the junction of a branch railway, so that the speed of the engine may be checked in proper time to prevent collision. The lights used for this purpose are generally exhibited at the place the approach to which they are intended to announce: but the distance at which light projected horizontally, may be seen by a person approaching in the line of its transmission is very variable according to the state of the atmosphere, which in our climate is subject to great and sudden changes, in regard to clearness and fog. These variations in the visibility of lights of extensive range are by no means confined within narrow limits, as experience too amply demonstrates in the case of lighthouses, whose range has been known to vary with the state of the atmosphere, from sixty miles down to two or three miles; and this evil is unhappily one of those which, in the present state of chemical and optical science, must, we fear, be pronounced irremediable. This defect, great as it is in regard to lighthouses, is, in the case of railways, materially aggravated by the excessive velocity of railway travelling. Any variation in the distance at which a signal light is first seen, must lead to great misconceptions as to the time of reaching a station, and all such misconceptions are fraught with the worst consequences, owing to the numerous sources of danger from the crossings of branch lines, the meeting of carriages on the rails, or the occurrence of other accidents, which may render a railway impassable. It is therefore obviously indispensable to safety that the signal-lights should be so constructed, that in all states of the weather they shall be constantly visible at the same point, and that this point shall be sufficiently distant from the station, the approach to which the signal is intended to announce, so as to allow ample time for checking the engine's speed before coming up to it; and upon no other grounds can the confidence of the public as to their security be reasonably based.

In the month of December last, it occurred to me in the course of conversation with my friend Mr. Errington, civil engineer, that although the variation in the visibility of lights of distant range must, according to our present knowledge, be regarded as an evil without remedy, it might still be possible, by means of some arrangement of the lights, to render *signals for railways constantly visible at the same point during every state of the atmosphere.* For this purpose, all that seems to be necessary is, to *limit* the range of the lights, and at the same time to increase their intensity in such a manner that the combination of a short range with great power may not merely render them capable of penetrating any fog however dense, but of producing, at a certain point, an effect so brilliant and striking as forcibly to arrest the engineman's attention. After considering the matter in various points of view, I came to the conclusion that the object could be best attained by placing the light considerably *in advance* of the station, the approach to which it is intended to announce, and by giving the beam such an inclination to the horizon, that its greatest power may fall upon the engineman's face, at so short a distance from the light itself, that it could not fail to be always visible at that point, even in the thickest fog.

According to the present practice, a comparatively feeble light is exhibited at the station whose position it is intended to point out, and this light, which is permitted to pierce the gloom until its power is greatly diluted by the united effects of its own divergence, and the length of its passage through a foggy medium, must necessarily be subject to constant variation of visibility with every change of the atmosphere. The change which I have to suggest, is to place a light of great power about a mile in advance of the station, and at the same time to limit its range by the depression of the resultant beam within such a distance as to ensure its being visible at all times.

The arrangement I would propose for the attainment of this object is remarkably simple, and consists in placing one of Fresnel's annular lenses, illuminated by a gas or oil burner, as may be most convenient, in a small chamber, glazed in front, and supported on a stage of carpentry of sufficient size to span the rails, and permit the train to pass under it; but the purpose might perhaps be equally well served by placing the stage at the side of the railway, and inclining the beam obliquely to the line. In order to limit the range of the lens to a short distance, and thereby to ensure the light being visible in all states of the weather at the same point, I would incline the instrument, so that the length of the trajectory from the lens to the observer's eye should not exceed about 700 feet, which falls far short of the distance at which the light of the lens would be obscured even in the thickest fog. I may remark that the inclination of the lens is too small to require any correction in the position of the flame; but this could be easily accomplished if necessary, more especially when gas is employed. In curved lines of railway the same effect might in certain cases be produced by placing the lens on a level with the observer's eye, and directing the refracted beam so as to cut the railway obliquely. In this case the limitation of range would be produced without the necessity of inclining the lens: but the principle of rendering the signal at all times effective, by combining a short range and a powerful light, is the same in both arrangements.

The advantage of this arrangement I conceive to be great, for not only would the light be at all times visible to the engineman on his arrival at the same point which, as already mentioned, is really the great object of signal lights; but it is obvious that his attention would be most effectually awakened by the contrast of suddenly passing from darkness to receive the full effect of a powerful light viewed from a short distance. One other advantage of the proposed signal light, I must observe, lies in its being peculiarly susceptible of any modification of colour, whether of a temporary or permanent kind, which the numerous and growing wants of an extended railway system may require. The alphabet of nocturnal telegraphy, wherever a distant range is required, is unhappily extremely scanty; for the practice of all Europe seems to have shown that, so far as colour is concerned, *red* and *white* are its *alpha* and *omega*; green and blue have been frequently tried; but cautious inquirers have all agreed in pronouncing them so equivocal when viewed from a distance, that they have been almost universally abandoned. These colours, however, and even much less marked varieties, although useless as distinctions for lights of distant range, are perfectly effective when viewed from short distances, as the brilliant display of an apothecary's window sufficiently proves.

I shall now add a very few words regarding what appears to me to be the chief arrangements which may, in practice, be found necessary for signal-lights on these principles: but I would not be understood as attempting to fix any thing permanently, for I am well aware that various modifications may be suggested by experiment, which I do not at present foresee in their full extent: in particular, it seems probable that the range of visibility which I have adopted in the following view of the details, falls short of what will be found quite sufficient in practice even during the thickest fogs, when a light so powerful as that which may be derived from Fresnel's lens is brought into play; and should this expectation be realized, the duration of the effect of the light, which depends on the range, might be increased beyond what I have ventured to state.

Referring to the above sketch, I would propose that the lens at L should be elevated 24 feet above the rails R R, or about 15 feet above as is consistent with a full effect from a flame placed in its principal focus. A more remote observer would receive the rays diluted by distance; while a nearer approach of the eye to the lens would render it necessary to adopt an ex-focal arrangement, so as to cause convergence of the rays. By the latter arrangement their divergence would be decreased, and the space covered by the light would be lessened not only in proportion to the decrease of divergence, but also to that of the cosine of the beam's inclination to the horizon. Both these circumstances would therefore combine to curtail the duration of the impression on the eye.

It may naturally be expected that I should say something regarding the duration of the impulse of the light on the eye; and upon this topic I shall, in absence of actual experiment, content myself with stating briefly the result of my calculations. If we suppose that an effective divergence of only 2° were to be obtained (and this is just one third of what is obtained from Fresnel's lens with the great lamp), I find that the light would spread itself along the horizon of the observer's eye between B and C to the distance of about 1000 yards, which, at the speed of 40 miles an hour, would be passed over in about 50 seconds, but at the ordinary railway speed of 25 miles an hour, about 80 seconds or 1⅓ minute, would be required. Such a flash of light falling upon the polished parts of the engine, and upon the observer's face, would undoubtedly act as a most effective signal. If, however, it should be thought advisable to increase the duration of the impression by spreading it over a greater length of the line, this effect could be easily produced by a slight alteration of the inclination of the lens, so as to cause the line of railway to cut the refracted beam more obliquely; but I by no means expect that any such modification would be found necessary in practice. The nearness of the eye to the lens, and the brilliancy of the flash, would, I am inclined to think, more than compensate for the shortness of the impression.

I must add a few words regarding the expense of these signals, which would be made up of the cost of erecting the scaffold of carpentry, the price of the lens, and the maintenance of the light. The price of the stage I shall pass over as a matter which may vary according to the circumstances of the situation and the taste of individuals; but the cost of the great annular lens does not exceed 40*l*.; and if a smaller sized lens, which I think would be found quite sufficient for the purpose, were employed, the expense would not be more than 10*l*. The annual maintenance would consist of little more than the supply of a gas or an oil burner. The consideration of the expense, therefore, of maintaining such a system of signals at the necessary intervals on railways, is not for a moment to be set against the most remote risk of the least of all the numerous accidents, the records of which fill the public prints.

OBSERVATIONS ON THE MOTIONS OF SHINGLE BEACHES.

By Henry R. Palmer, Esq., F.R.S.*

From the Philosophical Transactions of the Royal Society:—read April 10, 1834.

The extraordinary prevalence of tempestuous weather during the last autumn having occasioned numerous disasters on our coast, the public attention was directed in an unusual degree to the imperfections of many of the harbours, and more particularly to those which are encumbered with accumulations of shingle. The access to harbours thus circumstanced is generally uncertain, and in tempestuous weather is frequently dangerous, or even impossible.

The action of the sea, which gives motion to the shingles and produces the evils complained of, has long been a subject of speculation; but I have not found that it has been systematically investigated. Indeed, the contrariety of opinions advanced upon the subject, sufficiently indicates an entire absence of that satisfactory mode of inquiry which is essential to the foundation of a safe and practical deduction.

Very little has been written upon the subject; and such facts as have been mentioned have only been referred to incidentally, or with a view to geological science. My present object is exclusively practical in its nature, and my observations have been limited to such facts as would assist in establishing certain and fixed rules for controlling the motions of the beach, so far as to enable us to preserve a clear channel through it in all seasons, and in every variety of weather; and to accumulate and preserve the shingles, where it is needful to do so.

The subject at first sight appears greatly complicated; and were it adheres; and therefore the following observations must be considered as restricted only to certain general principles, subject to a variety of modifications.

The principles which I propose to illustrate will (under similar circumstances) at all times exhibit the same phenomena, but for the sake of perspicuity I shall now only refer to the coasts of Kent and Sussex.

Section 1.

That the pebbles which compose the shingle beaches on these coasts are kept in continual motion by the action of the sea, and that their ultimate progress is in an easterly direction, are facts long known and commonly observed. The following observations are chiefly directed to the particular manner in which the motions are produced.

From a general view of the effects that I have noticed, it appears that the actions of the sea upon the loose pebbles are of three kinds: the first heaps up, or accumulates the pebbles against the shore; the second disturbs, or breaks down the accumulations previously made; and the third removes, or carries forward the pebbles in a horizontal direction.

For convenience I propose to distinguish these by the following terms, viz. the first, the accumulative action; the second, the destructive action; the third, the progressive action.

All the consequences resulting from these various actions are exclusively referable to two causes. The one is to the current, or the motion of the general body of the water in the ebbing and flowing of the tides; the other to the waves, or that undulating motion given to the water by the action of the winds upon it; and it is of considerable importance to the present inquiry that the effects resulting from each specific cause be separately considered.

The motion of the shingles along the shore is commonly attributed to the currents, the action of the waves being considered only as a disturbing force. That such a notion is erroneous will, I apprehend, presently appear; although I have to regret that I have not had the opportunity of obtaining such satisfactory information relating to the velocities of the currents in the channel, as would have enabled me to include every form of argument upon the subject. The absence of such information has also prevented me from deciding satisfactorily as to the sources from whence the whole body of shingle is derived, which, although not necessary for the practical purposes I have in view, would have given more interest to the subject, and would have rendered the elucidation more complete. I must, therefore, for the present, be content to pursue the motions of the beach after it is found lying along or near the shore; observing only that the materials of which it is composed are those of the various strata in the vicinity of the coasts, together with the ordinary sea sand, and such small particles as may have been brought to the shore by the floods of the various rivers.

That the current is not the force which moves the pebbles along the coast, will appear from the following reasons:

1st. If it were so, the direction of the motion of the pebbles would be determined by that of the currents; but while the direction of the currents will vary with the changes of the tides, we find that the direction of the pebbles may remain unaltered; and also that the motion of the pebbles is continued where no current exists.

2nd. Although the velocities of the currents may not have been ascertained with precision, yet it is known that the velocities generally along this coast, which can possibly act on the shingles, are not sufficient to give motion to pebbles of every dimension, which are in fact carried forward.

3rd. The motion of a current will not produce that order in which the pebbles are found to lie, which order (as will be hereafter shown) may easily be distinguished as the effect of the motion of the waves only.

The direction of the waves is determined principally by the wind, the prevailing direction of which on the coasts referred to is from the westward. Every breaker is seen to drive before it the loose materials which it meets; these are thrown up the inclined plane on which they rest, and in a direction corresponding generally with that of the breaker. In all cases we observe that the finer particles descend the whole distance with the returning breaker, unless accidentally deposited in some interstices; but we perceive that the larger pebbles return only a part of the distance; and upon further inspection we find that the distance to which each pebble returns bears some relation to its dimensions. This process is an indication of the accumulative action.

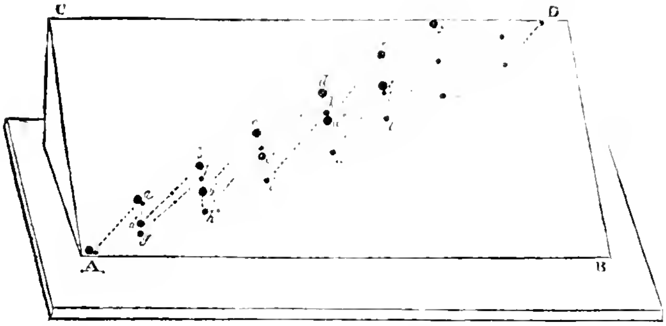
But under some circumstances, depending on the wind, it is found the level of the engineman's eyes; and that the point where the centre of the beam would intersect the horizon, A C, of his vision at E, should be about 700 feet from the lens. The impulse of the light would be most advantageously received at some point as near the lens

* The construction of harbours, piers, and breakwaters is likely to become of considerable importance to the engineering profession; we therefore propose to collect for publication in the Journal, such papers as have been written on the subject.

necessary to discuss minutely all the modifications arising from the variety of forms and local circumstances, it would perhaps be too much so for general description. I have, however, limited my investigation to those simple and unvarying laws to which nature always that pebbles of every dimension return with the breakers that forced them up the plane, and that these are accompanied also by others, which had been previously deposited, but which are in such cases disturbed by the waves; and by a continued repetition of the breakers acting in this manner, the whole of the shingle previously accumulated is immersed below the surface of the water. This process is an indication of the destructive action.

The particulars of the accumulative action, *combined with that of progression*, are explained as follows. (Fig. 1.)

Fig. 1.



Let ABCD be an inclined plane, representing that on which the loose pebbles move. Suppose the wind to blow in such a direction as to cause a wave to strike a pebble at A, in the direction of A *a*, and to the distance (*a*) up the plane, that point being the extent to which the force can reach. Now here the wave breaks partly into spray, and is dispersed in all directions: is partly absorbed, and descends in a shallow form, which rapidly diminishes in its depth, so that the pebble is soon left exposed, and therefore does not return the whole distance with the water, but is left at rest at (*a'*), being at a higher level than that from whence its motion commenced.

With the rise of the tide the striking force is also elevated; and by the repetition of the operation described through the different heights in succession, the further motion of the pebble will be represented by *a' b' b' b'*, &c., the distance in each step of its descent being something less than in that of its ascent, until it has reached the summit (*f*) determined by the height of the tide. Now if we suppose a pebble of less dimensions than the former to be struck from the same point, we shall find it raised as before; but because its surface is greater in proportion to its weight, and because from its less bulk it remains longer immersed in the declining wave, it will descend further, and follow the line (*a g*, &c.), and will not be left at rest till it has reached (*o*).

If, then, we suppose a pebble whose dimensions are less than either of the former, it will be evident that the point at which that will arrive on the highest level will be more distant still: hence it follows that the distance travelled horizontally by the pebbles during a tide will be in some proportion to their bulk, the specific gravities being the same.

(The pebbles do not in reality move in straight lines, but in a succession of curves; the straight lines are assumed here, and in other parts of this paper, to simplify the description.)

I trust it is only necessary to remark, that if the wind continue to blow in the same direction during the ebbing of the tide as through the flowing of it, the direction in which the waves will strike the shore will be nearly the same, and the progress of the pebbles will be urged by a similar action, and therefore their direction will also be the same.

In this action we observe a constant tendency to heap up and accumulate the shingles; and it is an interesting fact, that when the action has continued equally through a tide, the pebbles are left *in regular order, according to their dimensions*, the largest being uppermost, and the smallest at the bottom of the plane. I do not mean to state that all the largest are at the top, or that all the smallest are at the bottom, for it is evident that some of every size will be found at every level; but that if an equal measure (say half a peck) be taken from the different levels, the average of each specimen will exhibit in regular order the various dimensions.

The order in which the pebbles are thus found is, then, that by which the effect of the waves is distinguished from that of a current, the effect of the latter consisting only in its influence on the direction of the impinging and recoiling motions of the waves, by which the motion of the beach may in a small degree be accelerated or retarded.

Section 2.

In the illustration of that action of the sea which breaks down and removes an accumulation, I propose referring to my observations in the order in which they were made. My attention was first directed to this part of the subject in the neighbourhood of Sandgate in October last.

The accumulative action had been continued for a considerable time. The numerous groins erected near Folkstone to impede the progress of the beach, for the protection of the cliffs, had collected a bank of pebbles, which in some parts was five feet in height. The wind had so much abated as to be scarcely perceptible, but the sea had a motion denominated a *ground swell.*

The waves approached the shore nearly at right angles with it; but although in rapid succession, their forces were very moderate. These circumstances continued through five tides, by which time nearly the whole of the loose shingle had disappeared, including all that had been collected by the groins at Folkstone. The water being particularly clear, I was enabled to perceive distinctly the action upon the pebbles, and their motion downwards. I observed, that although every wave became broken and dispersed as usual, yet they followed in such rapid succession, that each wave rode over its predecessor while on its return, and thus produced a continual downward current, which carried with it the pebbles that were disturbed. That the pebbles were not removed far from the line of low water, would appear from the fact, that on the subsiding of the swell, it being succeeded by a light breeze of wind from the westward, the accumulation immediately commenced, and was restored to its former quantity by the action of four tides. I have subsequently had some favourable opportunities for making other observations on the effects produced by different rates of succession of the waves, and particularly at Dover, during the late gales, where the same actions were noticed. There I watched for an opportunity of witnessing that rate of succession which exhibited the destructive and accumulative actions in their smallest degrees; and I observed, that when ten breakers arrived in one minute, the destructive action was but just evinced: and that when only eight breakers arrived in the same period, the pebbles began to accumulate; which facts harmonized with my observations made at Sandgate and Folkstone, viz. *that the difference between the two actions was determined by the rapidity in succession of the waves upon the shores.*

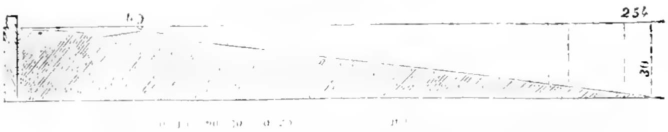
In the description of the accumulative action, I have assumed the forces to be directed obliquely with the line of coast, and have therefore necessarily included the progressive motion: but it remains to be explained in what manner the shingles are carried forward while the destructive action is going on.

It is known that the action and re-action of the waves give to the whole body of the water, within a certain distance from the shore, an undulating motion. The direction of this motion, when approaching the shore, will, to a certain degree, correspond with that of the waves upon the surface, and the direction of the recoil will also be affected in like manner; therefore the pebbles that have been carried down by the destructive action are moved forward through an angular course *beneath the water*, until, by the excess of the impinging forces over those of the recoil, they are again raised by the action of the water, and deposited where the destructive action has ceased, or where, from local circumstances, it cannot occur. The circumstances which are most unfavourable to the destructive action are those which least admit of the constant downward under-current,—an inlet, or narrow arm of the sea, for example. If we suppose a wave rolling through the mouth of an inlet, carrying with it a charge of shingles, it does not break as upon an inclined plane, but is dispersed in the general body of the water, which is comparatively quiescent; and there being no returning force, the shingle becomes deposited, and a bank is formed: and although the destructive process would act upon that bank if it could attain a certain height, yet the attainment of that height is prevented by the waves passing over it, and carrying with them, in succession, the shingles with which they are charged.

Section 3.

In fig. 2 is represented a section of the beach formed along the outside of Folkstone Harbour.' This section was taken with great accuracy, after the ground swell before referred to had removed most of the loose pebbles from it; so that the section may be considered as representing the plane upon which the progressive motion of the pebbles is carried on. Its slope is in the proportion of 1 to 9, nearly, and (with the exception of that part near the summit where there remained

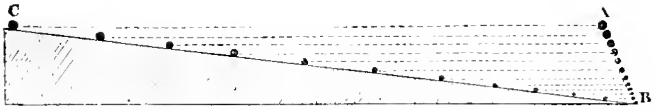
Fig. 2.



a bank of pebbles beyond the reach of the previous tides,) the surface of the plane corresponds very nearly with a straight line, which, considering that it is a natural formation, is a fact worthy of notice.

I think this plane may be considered as representing the average dimensions and inclinations of the surfaces over which the beach travels along this coast, and I have therefore generally assumed such an one for the present purposes. Upon such an inclination, the loose pebbles are in contact with each other; and although their depth upon the plane is constantly varying, yet, for the sake of conveying a general idea, we may assume the average to be about six inches, extending between high and low-water marks. When, however, the plane is less inclined, the same quantity of beach is spread over a larger surface, and its depth is diminished; and the pebbles are in some places so far separated as to exhibit the appearance of a diminished quantity. In fig. 3, this is illustrated geometrically

Fig. 3.



Let A B represent a plane on which all the pebbles are in contact, C B a plane considerably more inclined. If, from the centre of each pebble on the plane A B, a horizontal line be drawn to the plane C B, the position of the pebbles on the latter will be respectively at the various points of intersection.

Section 4.

There are numerous points on the coast at which the line of beach is apparently intercepted and its continuity destroyed, and the rock washed bare. Having sufficient evidence that the motion of the beach was continuous, I thought it important to ascertain in what manner the pebbles escaped past those places, and was happy in finding, upon investigation, that a valuable deduction could be made.

In the description of the accumulative action, it was remarked that the waves having struck the pebbles upwards, became dispersed, and were incapable of returning them to the level from which they were forced. But I now observed, that the surface of the rock, being very irregular, constituted numerous channels; so that the waves, instead of returning in a dispersed and weakened form, moved back in columns, which were of sufficient power to return every pebble that had been thrown up; and as these channels offered no impediment to the angular progressive motion of the pebbles, it was more rapid than on the ordinary plane surface. Here, then, was pointed out by nature a principle on which the shingles might be hastened forward, and their accumulation about any particular place prevented; and by simply reversing that principle, a method of accumulating or retaining the shingles, where they are wanted, is also suggested, viz. by the reduction of the descending force of the breakers.

The effect of confining the retiring breakers to a column is also exemplified in another manner, when the waves are driven directly upon the beach by a moderate wind, or such as would produce the accumulative action. A succession of waves, acting over the same lines of the beach, soon forms a slight depression, which continues increasing until it becomes a definite channel. The whole line of beach being thus acted upon, it assumes the form of a series of banks parallel with each other. The waves do not then recoil in a dispersed form, but, having broken, are again collected and returned through the channels, and remove all loose matter from them. While in this state, the beach has no progressive motion, but continues (to use a military term) "marking time," until, from the change of wind, an oblique direction is given to the motion of the waves.

Section 5.

The progressive motion of the beach may be easily traced along the coast as far as the bay called Sandwich Flats. The general character of the motion during its progress is that which is most favourable, under every circumstance, to the chances of becoming securely deposited. Every part of the coast is attempted by every variety of motion in its turn, until a place of final security is discovered.

The locality of Romney Marsh appears to have afforded the sought-for shelter, and now exhibits an extraordinary example of the accumulation, which, having been combined with sand, silt, and vegetable soil derived from other sources, has long been considered an acquisition to our surface of considerable value.

Although this tract has continued increasing to the present day, yet a great quantity of the beach travels past it, and we do not find any other accumulation of much extent between that and Sandwich Flats, beyond which there is no further trace of the shingle which we have so far followed, the pebbles to the northward of these flats being evidently those derived from the cliffs near about them.

On the approach of the shingle to the Sandwich Flats, it becomes gradually dispersed, owing to the increasing inclination of the plane, until it seems to disappear. A considerable extent of these flats has attained a height very little inferior to that of the high-water mark of spring tides; and it is so nearly horizontal, that the water does not partake of that undulating motion upon it which has before been adverted to.

On the Sandwich Flats there is a continual deposit of soil and silt, brought there from the interior of the country by the river Stour, and which, after its exposure to salt water, is particularly suitable for permanently uniting all the coarser or larger fragments with which it may become intermixed. So much of the materials which have composed the beach as may be conveyed to the higher parts of these flats are not likely to be again disturbed, because many days may intervene before another tide may reach them; and they thus become united to the surface on which they rest, and gradually contribute to its height.

The greatest motion of the pebbles being where they are exposed to the action of the greatest number of waves, we must look to the lower levels of these flats to trace the further course of the greater portion of the shingle. But even the slope of the surface of the lower levels is so very gradual, that the undulating motion of the water is proportionally diminished; *the action of the water then becomes greatest in the direction of the land.* While, then, we bear in mind the nature of the soil over which it acts, we find an almost insurmountable impediment to the further progress of the shingle, and are enabled to account for the rapid extension of the Sandwich Flats towards the sea, which, in fact, is only the continuation of that process which has been for ages in operation, and which has formed a large portion of those extensive marshes between the Isle of Thanet and the main land of Kent.

Section 6.

Having described those chief principles which regulate the motion of the shingles on this coast, and having traced their progress to a final destiny, I shall now proceed with some further general remarks referring to the application of the foregoing observations.

So much effect has been attributed to the motion of the tidal currents, that vast sums have been expended in attempts to divert the motion of the shingles to a distance from the general line of the shore, from whence, by the increased depth and velocity of the current, it has been expected they would be carried past a particular spot, through which a permanently open channel has been required. Such attempts have been made at various periods during upwards of two centuries at Dover, and more recently at Folkstone in the same neighbourhood. It is hardly necessary to observe, that such attempts have not been successful, and from the principles which I have laid down, their failure may be easily accounted for.

If a wall or pier be extended from the shore into the sea, it is evident that such erection will in the first instance impede and prevent the progressive motion. It is also evident, that the progressive is not necessarily combined with the accumulative action, but, on the contrary, where the former is impeded the latter is assisted. The accumulative action, therefore, continues until the angle formed by the pier and the line of the shore is occupied, and the pier being no longer an impediment to the progressive motion, that motion is again restored, and the general mass proceeds as if no impediment had existed.

The most perspicuous evidence of these results is exemplified at the harbour of Folkstone. Previously to the commencement of this exclusively artificial work, the beach travelled along the line of cliff in the ordinary way.

By extending the walls a sufficient distance into the sea, it was expected that a commodious harbour would be formed, and the shingles diverted so far into deep water, that they could not again appear above the surface until they were removed beyond the harbour's mouth.

The accumulation, however, immediately commenced, and continued as the work advanced until it became apparent that no other effect was produced upon it than a comparatively slight change of direction.

The entrance of the harbour being much encumbered with shingle, an additional pier or jetty was erected, and extended about two hundred feet further into the sea without having approached the effect intended. It is true that some advantage was derived from the extended pier, by increasing the distance between the most violent action of the breakers and the still water of the harbour. The shingles, therefore, pass the mouth in a more dispersed form than they originally did, and hence they do not so readily form a barrier, neither does its perpendicular height become so great.

Much valuable information on this part of the subject is recorded in Lyon's History of Dover, which, as it may at any time be consulted, is not repeated here. I shall only remark, that from the succession of experiments made at that place, the general result has been in a considerable acquisition of new land, which, although valuable in itself, is not the object intended to be obtained.

If, then, it be admitted that projecting piers will not prevent the encumbrance about the mouth of a harbour, situated as those referred to in the tract of the restless beach, it remains to be seen how far such works may be otherwise injurious.

While the accumulative action is going on, every abrupt projection from the coast is an impediment to the progressive motion of the beach until its angle is filled up. Such abrupt projections offer no protection against the destructive action; when, therefore, by the increase of wind, the action of the sea becomes violent, an accumulation previously caused by a projecting pier is rapidly removed, and again is rapidly deposited where it is not resisted. And there is perhaps no combination of circumstances less capable of resisting, or more favourable to the deposition of, the shingle, than is found in artificial harbours, shielded by an *abrupt* weather pier in a line of beach.

With a long continuance of violent winds from the same quarter, every accumulation of loose shingle is broken down, and is hurried forward, while it unremittingly appears to seek protection. During the recent gales every inlet within the tract of the beach was seriously encumbered with it; commenced with the heap accumulated by the very pier that was intended to prevent such an effect (where such existed), and increased by the successive arrivals of those more remote, together with that quantity commonly passing along the sloping plane, but now brought down by the destructive action and forced along with accelerated motion. * *

Many very interesting facts might be mentioned concerning the effects produced by the continued gales at various places on the coast, but I find that the description of them in sufficient detail to make them useful would extend this paper much beyond the limits assigned: I, however, trust that the reference to two of the most remarkable cases will be found sufficient to illustrate the principles attempted to be explained.

Section 7.

The only natural power by which the channels through the beach are retained, is the returning force of the water, which on this coast is generally scanty. And it is obvious, that however judiciously that force may be employed, it is but *remedial in principle*, and necessarily implies a previous evil. So long, therefore, as the cause continues to act, the remedy is prevented, and the harbour becomes inaccessible when protection is most required.

If on inspection of the great bank recently thrown up at Dover, we imagine it to be dispersed over several miles of the sloping plane, and assume the whole to be in continued and equable motion, it will immediately be inferred, that the quantity that would be passing a given spot at one time would be comparatively insignificant: and hence, since we have no reason to suppose that there will be a limit to the quantity, and since it has been shown that its motion cannot be prevented, it follows that the great objects in view must be attained, first, by securing permanently such accumulations as are necessary for the protection of land from the action of the sea, or useful by their addition to its surface; and secondly, by facilitating and inciting the progressive motion of that superfluous quantity from whence the evils complained of are derived: and therefore the uninterrupted and permanent welfare of the numerous harbours which communicate with the sea, through the extensive tract of the shingle beach, is dependent more on a *system of management along the coast*, than upon particular devices adapted exclusively to each separate case.

Engraving upon Metals.—M. Melloni has announced to the French Academy that M. Cirelli, of Naples, has been able to obtain plates upon metals by galvanoplastic methods. His discovery is to form immediately the plate completely engraved after a simple design. M. Melloni has submitted some of the plates to the inspection of the Academy. The process is not detailed, as Cirelli is preparing to secure a patent for it.

PREVENTION OF EXPLOSION IN STEAM ENGINE BOILERS.

The Gold Isis Medal was presented by the Society of Arts to Mr. Robert M'Ewen, Glasgow, for his Double Mercurial Safety-Valve for Steam Engine Boilers.

There are two evils against which it is especially necessary to provide in the construction of an apparatus for preventing explosion in boilers, viz. the possibility of the steam passage being intentionally closed, for the purpose of obtaining extraordinary pressure: and the failure of the self-action of the apparatus through the accidental derangement of its parts.

Mr. M'Ewen's apparatus consists of a pair of open tubes, the ends of which are immersed in mercury contained in cups connected with the boiler by a pipe. At the junction of this pipe with its branches for the two cups, is a three-way cock, the ports of which are so proportioned to the openings of the branch pipes, that the steam can neither be opened on, nor cut off from, both cups at the same time. The mercury tubes are proportioned in length to the greatest pressure which the boiler will bear with safety; the mercury will therefore be blown out of the acting tube into the dome at the top, whenever the pressure exceeds this limit, and will fall down through the other tube into the empty cup, while the steam blows out through a pipe at the top of the dome.* When the pressure is sufficiently reduced, the cock may be turned, and the cup which was last filled becomes the acting side of the apparatus.

On the 7th of April, a committee of the Society inspected the action of Mr. M'Ewen's mercurial valve, the apparatus having been attached to the boiler at the works of Messrs. Fairbairn and Murray of Mill Wall. The steam was opened on the mercury at a pressure of five pounds to the square inch, and as soon as it attained the pressure corresponding to the length of the tubes, viz. seven pounds, the mercury was blown, without any loss, into the dome and fell into the empty cup, while the steam blew out through the pipe at the top of the dome, and was condensed in a vessel placed to receive it for the purpose of experiment. On examination of the water in this vessel, not a particle of mercury was found in it. This result sufficiently proved the efficiency of the pipe, which is produced to some distance downwards within the dome, as represented in the section fig. 1, for the purpose of preventing the mercury from splashing out with the rush of steam.

As the action of this apparatus depends simply on a *physical* principle, viz. the opposition of the elastic force of steam to the static pressure of mercury, without the intervention of a *mechanical* obstruction of any kind, it cannot fail of acting, so soon as the pressure of steam exceeds the limit corresponding to the length of the tubes. The novelty of the invention is in the employment of a mercurial tube as a safe vent for the steam, these tubes having hitherto been used only as indicators of steam pressure, being long enough to allow the steam to attain a dangerous pressure without relieving it or giving any other notice of the fact than what may be observed by the eye.

REFERENCE TO THE FIGURES.

Figure 1 represents the whole apparatus in section. A the pipe connected with the steam boiler, B the hollow plug of a cock with a side opening at C, through which the steam passes into the area D, and pressing on the mercury causes it to rise in the tube E till its weight counterbalances the force of the steam; the tube E opens into the chamber and dome F, to which there is free access for the atmosphere through the neck G; if, therefore, the steam should at any time exceed the due pressure which is limited by the length of the tube E, it will drive all the mercury before it up this tube into the chamber F, and will escape through the neck G; in the meantime the mercury will enter the opposite tube H through the small hole I, and flow down into the other vessel J, where it will be ready again to act as a safety-valve as soon as the attendant has turned round the plug B by its handle K, thus cutting off the communication of the steam with the vessel D, and opening it into the vessel J. The construction of both sides of the apparatus being exactly alike, the tube E having an aperture at L to receive the mercury from the chamber F, this operation may be repeated as often as the escape of the steam gives notice of its being necessary. The bottom of the chamber F, though straight from L to I, is curved like a trough in the cross diameter, as shown by the curve under F, to conduct all the mercury through the hole I or L, whichever may be opposite the acting tube.

---

* Mr. M'Ewen intends that an alarm-whistle be placed in this opening, and also that the apparatus serve as a gauge for indicating the variation of pressure, by means of graduated float-rods in the mercury tubes.

Fig. 2.

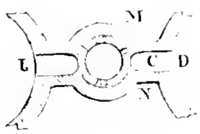


Fig. 1.

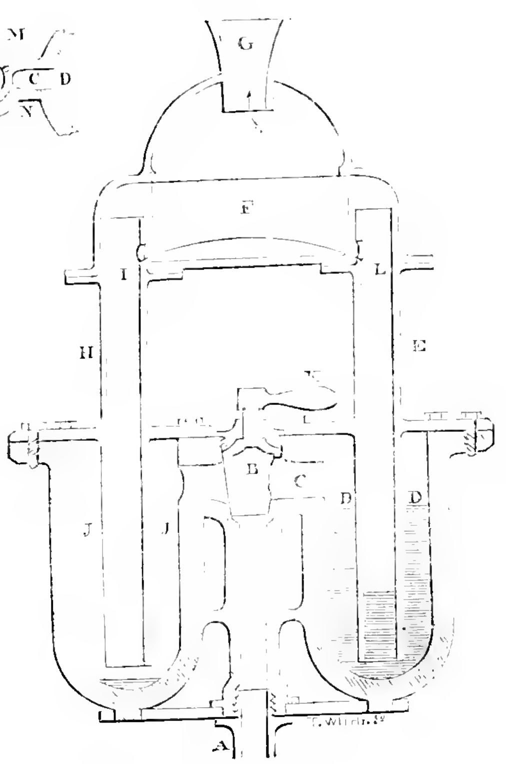

For the sake of perspicuity, only one side opening from the plug B has been adverted to. But the plug is always made with three openings, as shown in fig. 2, at C, M, and N: by which it will be seen that it is impossible to shut more than one of the chambers, D or J, at the same time. The engineer, therefore, has not the power of completely shutting off the steam by means of the cock, nor could a successful attempt be made to effect this by plugging the pipe in the dome, the material of the latter not being of sufficient strength to bear as high a pressure as the boiler.—*Trans. Soc. Arts.*

S. L. AND THE PROFESSOR OF ARCHITECTURE.

Sir.—The freedom of some of the comments in my last Fasciculus must, no doubt, have startled your correspondent S. L., and also convinced him that I fully act, *i. e.* write, up to my motto, which is very much more than can be affirmed of every one who bears a motto. It is evident he considers me as having made much *too* "free with the Professor of architecture at the Royal Academy;" just as if the Professor was a schoolmaster—some village Solomon whose sceptre is his birch, and whose subjects are bound to listen with awe to whatever he utters. What indecorum there can be in animadverting upon opinions enounced by the Professor in his public capacity, I cannot possibly conceive. Similar freedoms are taken every day with persons and personages who are quite as important—at least people fancy them so—as Professors of architecture: a truth well known to Lord Melbourne, and Lord John Russell, and to a great many others before them.

It is, I believe, generally understood that the freedom of remark which would be indelicate and reprehensible towards private individuals, is perfectly allowable towards public men, and those who hold public situations which give an influential authority to their opinions. On the last account it is, that opinions promulgated *ex cathedrâ* should be narrowly watched and scrutinized; and if they will not bear a little rough handling when examined, they are fit only to be bandboxed in lavender, and brought out, not in the lecture room, but in the drawing room.

For my part, I hold the squeamishness and affected delicacy which usually pervades architectural criticism to be not only exceedingly silly, but exceedingly mischievous into the bargain; for they tend in fact often to stifle criticism itself just at the very time when it might be applied with success; and grant impunity to some of the greatest delinquents, and to the abominations perpetrated by them, under the paltry pretence of its being a delicate and invidious task to speak of men and matters belonging immediately to our own day. This excessive caution—not to call it time-serving obsequiousness and cowardice—is almost peculiar to those who write on architecture: most certainly we find very little of it in literary criticism: where the merits of living writers, let them stand ever so high, are often discusssed with a freedom that is almost startling, or at the best very unceremonious.

However, all that I have just been saying will be thought little better than evasive remarks, under cover of which I am fain to sneak off and screen myself from the allegation made by S. L., and therefore now say in reply to it, that erroneous or not, the impression left upon myself, and a good many other persons also, I believe, was that the Professor's views were so far unfavourable to Gothic architecture as to discourage it most decidedly at the present day. To be sure he expressed a decent "for-good-manners'-sake" admiration of it, just of that sort and no more which may be professed for any other by-gone and worn-out style of the art—for Egyptian or Byzantine curiosities in it. An enthusiastic devotee in his rapturous reverence for the sublime Sir Christopher Wren,—who, by the bye, produced Temple Bar and sundry other pieces of veritable architectural bathos—the Professor is evidently ill-disposed towards the practical application or adoption of Gothic at the present day. So likewise is S. L.; and therefore both of them may probably object to the style selected for the new Houses of Parliament, and may also greatly prefer Buckingham Palace to Windsor Castle—perhaps regret that Mela Britannica's advice was not taken in regard to the latter structure; had which been done every vestige of it would have disappeared, and a low moderate-sized Grecian edifice, a mere parallelogram in plan, would have been substituted for it, as worthier to grace the acropolis of Windsor!

It would seem that mullioned windows do not accord very well with plate glass, but "are more suitable for casements with small panes of glass than for the large squares now in use." Now it may fairly be admitted that small panes do not at all disfigure Gothic windows—do not produce the same mean and palty effect they would in others: but it does not therefore exactly follow that they are indispensable to propriety of character, because, if well designed in other respects, the windows lose nothing by each compartment being filled with single plates of glass. On the contrary, the use of glass of such dimensions removes in a great measure the objection apt to be entertained against mullions of suitable proportions, as obstructing light; because, owing to the greater size and transparency of the glass, as much light is transmitted through the same space interrupted only by bold mullions, as where the mullions are very scanty, and the general surface consists of a meshwork of lead in which the glass is fixed. The chief difference between a window with small panes and one without divisions of the glass, is that in the latter case, if the entire aperture loses somewhat of the character of a glazed Gothic window, it will still resemble what is equally beautiful in the same style, namely an open screen with unglazed compartments.

But if Gothic is inapplicable because of so slight a difference as that arising from the windows being glazed with large pieces of glass instead of diminutive panes, how is it possible for us to reconcile ourselves to the infinitely greater departure from the genius of Grecian architecture, by introducing, as we most freely do, into that style, features not only unknown to, but absolutely at variance with it, not only windows, chimneys, balustrades, attics, &c.; but successive tiers of windows and windows throughout, windows within porticos, &c.? Again, small panes set in lead are to the full quite as unsuitable for windows in Grecian or Roman architecture, as they are suitable in the Gothic style, which being the case, have we not a right, according to S. L.'s notions of consistency and propriety, to be very much shocked at the semi-Gothic or Gothicly glazed windows of St. Paul's cathedral?

S. L. talks of the "difficulty of persuading persons to adopt Gothic, who are not possessed of antiquarian taste." How happens it, then that we have so many soi-disant Gothic churches and Gothic mansions which are in utter defiance of antiquarian taste or any other? why are we doomed to behold so much hole-in-the-wall Gothic—so many castellated fancies *à la Lugor?* For no other reason than because there is a bigotted and fashionable prejudice for the mere name of the style among persons who have not the slightest notion whatever of the style itself. The difficulty is not to persuade people to adopt, but to dissuade them from thinking of at all adopting a style which they will not allow to be properly treated.

Again, S. L. assures us that when modern architects design in the Gothic style, their object is imitation, but that when they employ Grecian or Roman, their aim is INVENTION!! Now no man would have ventured upon so very bold an assertion unless he had previously fortified himself and screwed up his courage to that pitch by an extra iose of claret or champagne, it being most palpable and notorious that all our Anglo-Grecian architecture betrays UTTER WANT OF INVENTION. Invention forsooth! then invention must consist in making fac-similes of Grecian columns, and poking plenty of sash windows between them: or in showing ugly chimneys, garret windows, and skylights over Grecian entablatures more faithfully than tastefully copied for the nonce, or if invention be occasionally shown, it is done after the fashion of Nash and Smirke, the former of whom has given us a Grecian Doric order in a palace, without triglyphs or even any division of frieze and architrave in its entablature, while the other has introduced doors not at all better than those of a stable or coach-house into the *classical* portico of Covent Garden theatre, *said* to be copied from that of the Parthenon, and whose columns some unlucky gin-and-water critic has lescribed as Ionic!

If S. L. can now explain away some of his own very awkward and untoward remarks, all well and good. To do so would at least display some ingenuity. All that I am afraid of is, that he will not make the attempt, but that he will henceforth be cautious of getting into a scrape by taking the part of the Professor of architecture, and leave the latter either to defend himself, or to submit to the incorrigible sauciness of

CANDIDUS.

THE ROYAL EXCHANGE.

SIR—If I am rightly informed the design for the New Royal Exchange has undergone considerable changes and modifications, especially as regards the interior court, in respect to which, if no other part, there certainly was great room for improvement, therefore as far as architectural character is concerned, I am willing to believe that improvement has been made. But why is the Exchange itself to be an open court at all? others besides myself have asked the same question—at least have animadverted upon the absurdity of making the area in which the merchants are to assemble an uncovered one, with no other shelter from the weather than what will be afforded by the ambulatories around it. The inconveniences attending such a plan are obvious enough; what countervailing advantages are expected it is difficult to guess, but it may be presumed that they are sufficiently important ones; consequently it would be but proper that they should be stated, if only in order to exonerate those who have control over the building from the charge of being guided as to so very important a point solely by obstinate caprice, and adopting what will be a serious inconvenience for no better reason at all than because it existed in the former structure—when, by the by, it was at one time contemplated to obviate it by covering in the open area. It would seem that now it is known that the building is to be erected by Mr. Tite, all interest in regard to it has entirely subsided. This ought not to be; nor ought such matters to go to sleep, and be treated as if utterly indifferent, because no one has now any thing farther to expect from any change that may take place. If reasons or any thing like reasons can be alleged for leaving the body of the Exchange entirely exposed to the weather, let them be stated and then we shall know on what grounds it has been determined to adhere in the new building, to what many considered an inconvenience in the former one.

There is, I find, an article on the Royal Exchange in the Penny Cyclopœdia, in the course of which objection is made to the merchant's area being left uncovered in the new structure. What is there said, however, is not likely to attract attention—at all events not immediately, or so much as a few lines in your Journal.

I remain, &c.,

CIVIS.

London, April 14, 1841.

MR. MUSHET'S PAPERS ON IRON AND STEEL.

SIR—I lately had for the first time an opportunity of looking into Dr. Ure's very elaborate dictionary, and on referring to the article on Iron I was a good deal surprised to find that a table of the proportions of charcoal used in the fusion of bar or malleable iron to produce the various qualities of steel and cast iron, and published by me in the Philosophical Magazine nearly 40 years ago, had been subjected to severe and unmerited censure on the part of Dr. Ure for its want of accuracy.*

As this table (along with many papers principally on the subject of iron) has lately been republished at a very considerable expense, I consider it behoves me to protect the property so created, and to take care that where the work is free from error, it shall not suffer any deterioration by my silence in respect of the criticisms of others, in whatever spirit they may be expressed.

The criticism to which I allude (page 716 of the second edition of Dr. Ure's Dictionary), is evidently borrowed from Karsten, but as the matter does not stand in the Dictionary in inverted commas, I am entitled to assume that it contains Dr. Ure's opinion on the subject, and shall deal with it accordingly. It is as follows.

"According to Karsten, Mushet's table of the quantities of carbon contained in different steels and cast irons is altogether erroneous. It gives no explanation why, with equal portions of charcoal, cast iron at one time constitutes a gray soft granular metal, and at another a white hard brittle metal in lamellar facets. The incorrectness of Mushet's statement becomes most manifest when we see the white lamellar cast iron melted in a crucible lined with charcoal take no increase of weight, while the gray cast iron becomes considerably heavier."

In this extract two facts are alleged, namely, first, that the product obtained at different times by the fusion of the same quantities of the same iron with similar proportions of charcoal is irregular: and secondly, that gray cast iron acquires weight by its fusion with charcoal, while white iron does not. I deny both these allegations,—but supposing they were true, what has my table of proportions to do with them?

It is assumed by Dr. Ure that the table gives the atomic proportions of carbon *united with*, and *existing in*, the various qualities of steel and cast iron, whereas it only professes to give the proportions of charcoal required to be *presented to* bar iron in the crucible to afford the various qualities of the metal before alluded to, and this it does with a degree of accuracy which I challenge Dr. Ure and Karsten to disprove.

The experiments show in the clearest manner that charcoal is absorbed by iron; that gray iron absorbs a greater quantity than white, and that steel requires for its production a less proportion than white.

To guard against the inference which has been so inconsiderately drawn by Dr. Ure, the following passage was inserted in my work.*

"Although this is the quantity of charcoal necessary to form these various qualities of metal by this mode of syntheses, yet we are by no means authorised to conclude that this is the proportion of real carbonaceous matter taken up by the iron, seeing that in experiments Nos. 1 to 6 inclusive, the weight gained by the iron was upon the average equal only to 1-21$\frac{8}{10}$ part, whereas the charcoal which disappeared in the different fusions amounted to 61¼ per cent. of the original quantity introduced along with the iron."

Having in this paragraph taken the precaution to guard against misrepresentation, I am at a loss to account for the conclusions at which Dr. Ure has arrived.

It is quite evident that both he and Dr. Karsten are puzzled with some results for which they have not been able to account. They cannot, it would seem, explain why "cast iron (query, white, gray or motled) with the same proportion of charcoal sometimes makes white iron, and sometimes gray." Having had some experience in the treatment of iron, it is barely possible that I may be able satisfactorily to solve the difficulty, the weight of which they have flung upon my table of proportions.

I must in the first instance be allowed to deny the alleged fact, namely, that the same iron and charcoal are so capricious as at one time by their fusion to produce white cast iron, and at another time gray. The same substances which have once made gray iron will, if the operation be similarly conducted, do so on every occasion, and the same remark holds good in respect to the other varieties of the metal.

In order to understand this curious and not unimportant subject, it must be laid down as a maxim that the affinity between iron and carbon depends upon the degree of temperature which the iron will withstand before it enters into fusion: the higher the temperature short of fusion, the more rapid and extensive will be the combination: and the converse is equally true.

Hence the unerring certainty with which malleable iron and steel unite with carbon in the crucible, and become with an increase of weight rich carburets of iron. The same remark is applicable in degree to refined metal, which when of the purest and whitest fracture, will with its appropriate dose of charcoal also pass into the state of the most perfect gray iron. But the case is most materially altered when the experiment is performed with common white pig-iron or with gray: the greater fusibility of both these states of the metal does not leave time for the action of affinity to take place between the iron and charcoal, so that even with a higher proportion of charcoal the results come from the crucible to all appearance unchanged as to quality.

* See Mushet's papers on iron and steel, published last year by Mr. Weale.

* Page 526, towards the bottom.

This difference in the fusibility of the various states of iron affords a clue to the mystery which seems to have puzzled Drs. Ure and Karsten, who may perhaps have still to learn that charcoal never combines with iron after it has become fluid, and that the union is always effected by a process of cementation.

Suppose then that an experimentalist were in the first instance to fuse refined metal (which is the whitest of white iron), with a certain portion of charcoal, and to obtain a soft gray granular metal, this result would be uniformly obtained so long as the same substances were used, but were he to substitute for the refined metal, white cast iron, (which, to an unpractised eye, is not easily distinguishable from the other), and fuse it with the same, or with a greater quantity of charcoal, the result would not in this case be gray, but white cast iron, of the same appearance as when introduced into the crucible.

But it by no means follows that white pig, or cast iron, cannot be converted into gray iron in the crucible, for however great its fusibility, yet if a portion of those earths whose affinities for carbon are developed at page 553 of my work, be introduced into the crucible and fused along with white cast iron, and even a minimum doze of carbon, the result will be gray iron of the best quality. In short the same iron which when fused with half its weight of charcoal alone, comes out of the crucible white, will by the introduction of the earths be converted into rich gray iron with an increase of weight, and this result will be obtained with only $\frac{1}{25}$ or $\frac{1}{30}$ of its weight of charcoal.

Your's, &c.,
D. Mushet.

(To be continued.)

THE LARGE WATER WHEEL AT COLEBROOK DALE.

Sir—Thinking a short description of a water-wheel of no ordinary dimensions may be worth your notice, I send a slight sketch and a few of the principal dimensions of one erected in Colebrook Dale, Shropshire, it works an oil and colour mill, but as the speed and the supply of water vary considerably, no correct estimate of the power can be obtained, but it probably does not exceed 3 or 4 horses' power. The speed is generally about one revolution in three minutes, or 1·39 feet per second; part of the water comes on to the wheel at the top and part about 25 feet lower down.

Fig. 1.

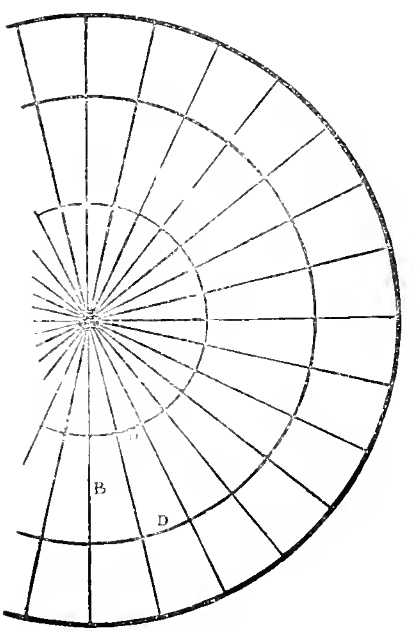

Fig 2.

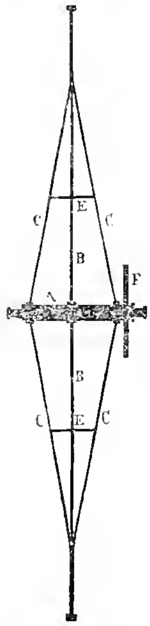

The principal dimensions are as follows:—diameter out to out, 80 feet, 28 arms B, 8 inches by 3 inches; side stays C, two to each arm, 4 inches by 3 inches; the arms and stays are braced together by two circles D D, 4 inches by 3 inches; and by cross stretchers E, of the same dimensions. The buckets, of which there are 280, are 9 in. wide at the top, 5 in. at the bottom, 16 in. in breadth, and 10½ in. deep. The shaft A is of cast iron hollow, 14 ft. 8 in. long between the bearings, 26 in. diameter, with mortice holes cast in to receive the arms and side stays. The arms are of pitch pine, all the other parts are oak. The spur wheel F is 15 feet diameter. The breadth of the lines in the drawing are as near as may be the dimensions of the different parts.

Fig. 3.

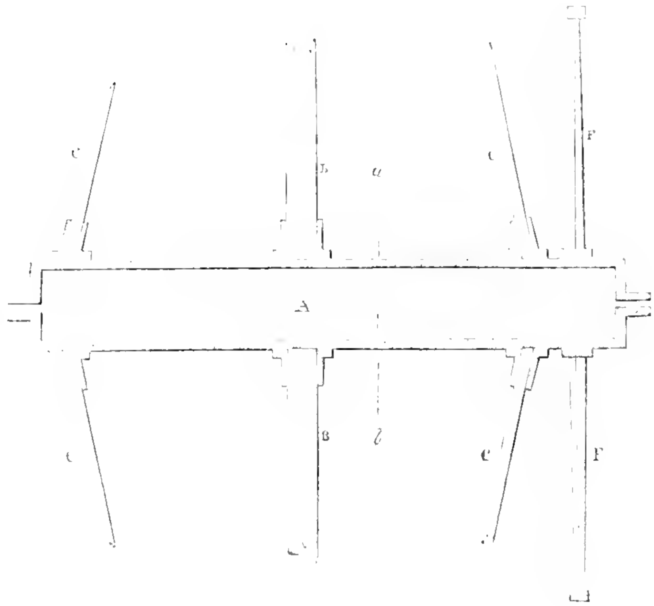

Fig. 4.

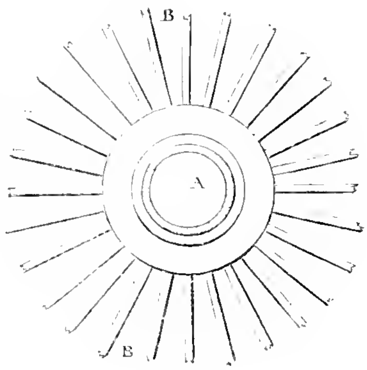

Fig. 5.

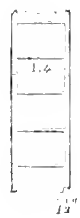
Fig. 6.



Scale of enlarged parts figs. 3, 4, 5, 6—quarter inch equal to a foot.

Fig. 1 is an elevation of the wheel; fig. 2 a section; fig. 3 an enlarged section of the shaft A taken longitudinally, showing the manner in which the arms B B, and stays C, C, C, C, are fixed, and the spur wheel E, E; fig. 4 a transverse section of the shaft from a to b, showing the arms; fig. 5 is a section; and fig. 6, front view of the buckets.

I remain, &c.
H. C.

Railway Works in France.—The Havre Journal, in noticing the arrivals of wagons and workmen for the Paris and Rouen Railroad in that port, says that the wagons have been hired from the London and Southampton Company at a much lower price than they could possibly have been in France, and that the workmen who have been sent over, are all chosen from the most sober and laborious of their class that could be found in England. This journal takes the opportunity of pointing out the activity and energy shown by the English engineers, and the Paris and Rouen Company, and holds up their example to the notice of all engaged in France on similar works.

CAPTAIN CARPENTER'S PATENT QUARTER PROPELLERS.

In the Journal for February last, page 56, we gave an abstract of the above patent, we are now enabled through the kindness of the Editor of the *Mechanics' Magazine*, to give the annexed engravings, which better explain the action of the Propellers, together with an account of some experiments communicated by Captain Carpenter.

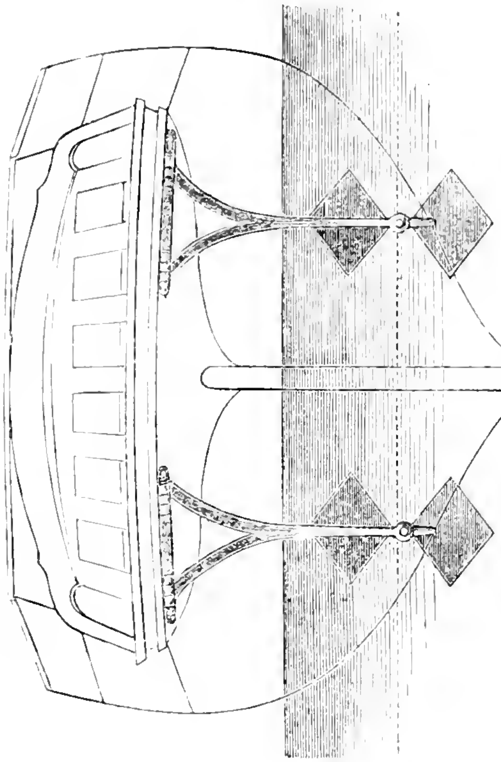


Fig. 2—Stern view

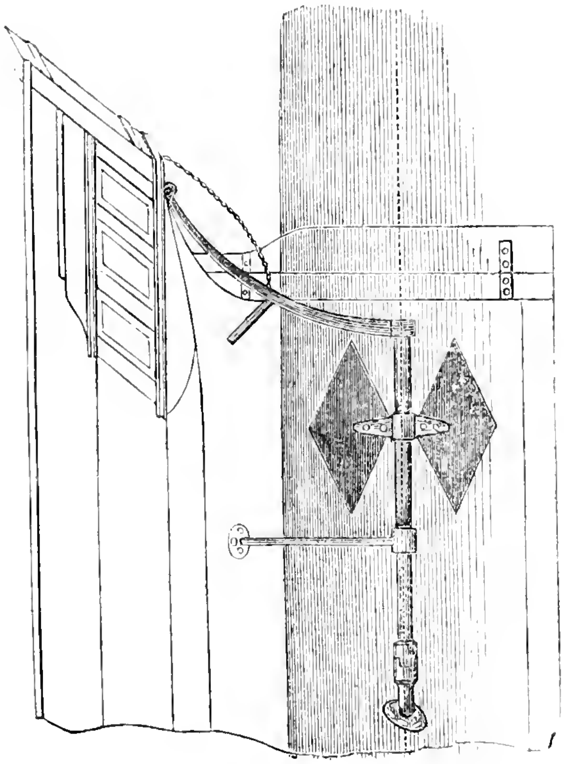

Fig. 1—Side view of the Propellers.

"The first experiments (on any thing like a large scale) were on board the *Aerolite*, a vessel 69 feet long, and 9 feet beam. They were intended only to ascertain how far the apparatus was adapted to sailing vessels, for the purpose of moving them about in calms, or as an auxiliary to the wind and sails. The powerful effect produced by the rotation of these 'quarter propellers,' even by manual power, was enough to establish the fact, that any vessel, however large, may be moved in an opposite direction to that line in which the force is applied, quicker or slower, according to the extent of the motive power.

"The next experiments were made with a model of a steam-boat, which is now exhibited at the Polytechnic Institution. This model is supplied with the means of applying a great variation of power to the propellers, and it admits also of great variation in the shape of them, by which means I have had an opportunity of judging upon the merits of screws, sections of screws, and planes; and of testing the angle of incidence, the shape of the vane or blade, and the relative proportions they should bear one to the other, according to the power applied. Although a screw is decidedly a powerful instrument in the water, I must nevertheless give the preference to the plane and to the figure shown in the accompanying drawing, because it produces the greatest speed with the least sacrifice of power, more especially when the vanes are set at the angle of 30 or 35° to the axis of the shaft. And here I would remark, and hope without presumption, that if any merit may be attached to this part of my invention, it consists in the discovery by careful experiment, that a plane having the proportions of my propeller, as represented in the drawing, will, when set at the above angles, and revolving in the water, impel a vessel by means of a locomotive power, and the resistance offered by the fluid, with a greater effect than any other instrument yet adopted in navigation, which may be proved by mathematical demonstration.

"The next experiment was made in a boat 21 feet long, and 4 feet 8 inches wide. It is necessary here to remark, that only one propeller was used, and that was placed in the stern. The object of which was, to test the shape of the triangular propeller against the screw, and other propellers with the same power, the same position, and the same machinery; but it is so difficult to make everything bear in an equal proportion, that I doubt whether the experiments can be considered conclusive. I do not apprehend there would be so great a difference as 3 to 6 between Mr. Rennie's propeller, Mr. Smith's screw, and my triangular propeller, as stated in your journal, if the experiments could be made equal in every respect, but that is impossible. Mr. Rennie's experiments, I believe, were made in a heavier boat than the one I used; and although there may not be much difference in the area of the midship section, still as there might have been a difference in the strength of the men and other circumstances, I do not think a comparison could be established; I therefore only presume to give you for data this fact, that with the very same propeller as I now send you, the boat was propelled with two men turning the winch, 88 measured yards in 33 seconds, and sometimes in timing it, it appeared to be 30 seconds—the propeller making 119·5 revolutions in that time."

"A screw propeller placed in the dead-wood of the *Archimedes* Yacht, has, it would appear from the public papers, fully established equality of speed with the common paddle-wheel. This propeller differs in *form* and *position* from the '*quarter*' propellers to which this paper immediately appertains, but the *principle* is the same; and on the ocean it establishes that main that principal fact, which the small model in the Polytechnic Institution under all its disadvantages also fully bears out—'*equality of speed*,' even in these early and imperfect essays. In the '*quarter*' propellers applied to this model will be found, a more direct and faithful adherence to nature's prototype, and in their rapid rotatory action in the water, under the most favourable angle of incidence the blades display, the combined powers of wedge and screw. No back-water ruffles their silent course. A gentle undulatory ripple marks the tract described by each propeller, similar almost to that which follows the action of the tail of a fish when swimming rapidly near the water's surface. The same obedience to the helm with equal facility of backing astern may also be observed, and in case of accident to the rudder, the power of steering is practicable by their alternate and combined actions."

Eastern Counties Railway.—On Wednesday the 7th ultimo, the first stone of the New Bridge over the river Chelmer, in the parish of Springfield, about to be erected to connect the embankment of the Eastern Counties line, which has been some time in the course of formation, and which is now traversed by means of a wooden viaduct, was laid by Mrs. Braithwaite, the lady of John Braithwaite, Esq., the engineer-in-chief to the company. The design for the bridge is distinguished by that neatness which characterizes those already erected upon the line, and will consist of three arches, each of 45 feet span. It will be 43 feet in height from the surface of the water to the coping. —*Kent and Essex Mercury.*

MESSRS. HANCOCK AND PETTIT'S PATENT RAILWAY TRAIN CONTROLLER.

(From the Railway Times.)

Fig. 1.

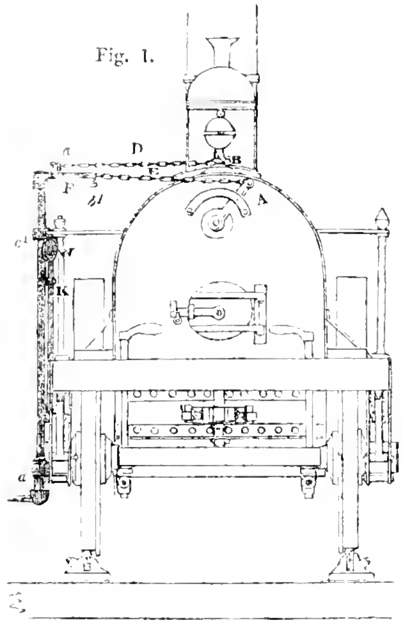

Fig. 2.

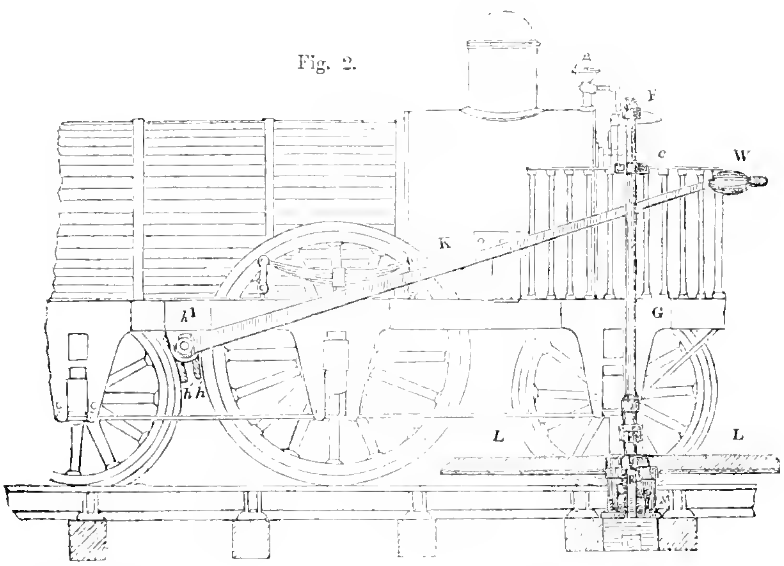

Fig. 3.

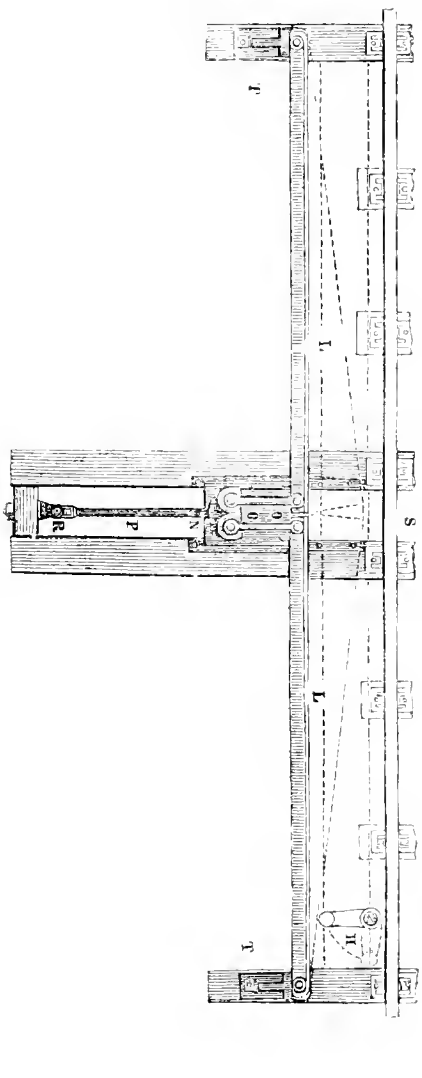

Fig. 4.

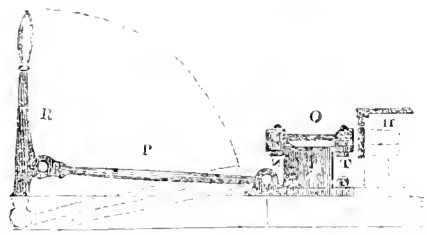


THE invention* is described as consisting in "certain mechanical contrivances and arrangements, by means of which common railway trains running upon railways of the ordinary construction, may be always brought to a stand without the agency and independently of the will of the engine-driver, guard, or other person or persons thereon, or travelling therewith, and at any given distance from a station or at any part of a line where it may be deemed advisable to have such independent means of stoppage provided."

The "mechanical contrivances and arrangements" divide themselves into two branches, the first including those which relate to the engines and carriages, and the second those which relate to the road-way.

I. The additions proposed to be made to locomotive engines for carrying this plan into effect are represented in the accompanying engravings, figs. 1, 2, 3, and 4.

Fig. 1 is an end elevation of a locomotive engine with the apparatus attached, and fig. 2 is side view thereof; fig. 3 is a plan of one of the rails and apparatus attached on the ground, fig. 4 is a side view thereof. A is the handle of the steam regulator, and B is the handle of the steam whistle. These handles are each fitted with loose collars, but so as not to interfere with the common mode of using them by hand; each collar has a projection to which the ends of the chains D and E are attached respectively, F is a horizontal lever fixed upon the spindle G, carrying the pins *a* and *b*, and to the two loose collars on these, the other ends of the chains are connected in like manner. The vertical spindle G is secured near the top by the bearing *c* fixed on the projecting rail; from this it descends through the eye *d*, attached to the guide plate of the axle on which it is supported by a collar, and H is a crank lever fixed on the lower extremity.

"When the engine is running, and the whistle shut, the several parts described are in the exact position shown in the drawing, viz. both

* The patent is in the name of Mr. Pettit, but Mr. Hancock and Mr. Pettit are joint proprietors of the patent right.

the chains D and E strained tight, and the crank lever H standing out at a right angle to the side of the engine.

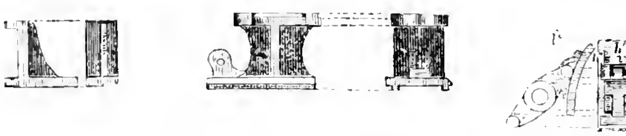
"Now, it is obvious that by fixing any apparatus on the roadway outside of the rails, by means of which the lever H may be pressed against, as the engine passes, to the extent of turning it about one quarter of a revolution, which will cause the two chains D and E to move with it, the steam will be shut off from both the cylinders, and simultaneously turned through the whistle.

"It may be proper, however, here to point out, that although the steam regulator, and whistle handles A and B, are connected to the lever F by chains, yet those handles can be worked by hand independently, either for the purpose of shutting off or putting on the steam to the engines, or blowing the whistle in the usual manner, leaving the crank lever standing in the position of fig. 1.

"Rods sliding in tubes on the principle of the telescope, admitting of the requisite contraction and expansion of the intervening distance, may sometimes be found convenient substitutes, for the chain D and E or any other suitable contrivance may be employed. A vertical instead of a horizontal action may be given to the lever by fixing it on a short horizontal axis, connected to the top of the spindle G by a small pair of mitre wheels, and supporting it by bearings fixed upon the most convenient part of the engine or carriage, or by any other mechanical means as circumstances may require."

II. The apparatus proposed to be affixed to the roadway to act on the combination of levers which has been just described, is also represented in figs. 1, 2, and 3, and in further detail in figs. 5, 6, 7, and 8.

Fig. 5. Fig. 6. Fig 7. Fig 8. Fig. 9.



"There are four sleepers of sufficient length to extend from under the line of rails to receive the apparatus fixed upon them in the manner shown in the fig. 3. Upon the two outside ones are bolted the blocks T T, of which figs. 5 and 6, represent an end and side elevation. The two middle sleepers are connected together about a foot asunder by the cross piece, and they form beds fortified with plates for the carriage N to slide upon; figs. 7 and 8, represent an end and side elevation of this carriage, showing two ribs cast upon the bottom to drop between the beds for the purpose of keeping the carriage in a proper position, during its backward and forward travelling motion. L L, are two pieces of strong angle iron, though any suitable material and form may be employed, which move on entire pins, fixed in the top of the blocks T T, while their other ends rest upon the end of the sliding carriage N, to which they are coupled by links O O, moving on centre pins fixed in the back end of the carriage N. One end of the rod P is received by the jaws cast on the carriage N, in which it moves freely upon a pin, and the other end is forked, and forms a movable joint with a piece or tongue projecting from the edge of the lever R (see fig. 4), and the fulcrum of that lever is fixed to the cross timber morticed into the sleepers, fig. 3. By joining the connecting rod P to a piece projecting from the edge of the lever R, the lever and rod, when the lever is put down will form a line occupying the position marked by the dotted lines in fig. 3.

"In the position in which the apparatus is shown in fig. 3, the pieces L L, or the slants as they may be termed, are parallel to the rail S: and, of course, stand clear of the crank lever H, which is carried by the engine (see fig. 1), but when it is necessary to act upon the lever H, in order to stop the train, the lever R must be depressed, which operating on the sliding carriage N, through the intervention of the rod P, advances or thrusts it forward together with the centre ends of the slants L L, towards the rail S to the extent of the dotted lines (see fig. 3), which are then in the position to act upon the crank lever H, when brought into contact by the advance of the engine.

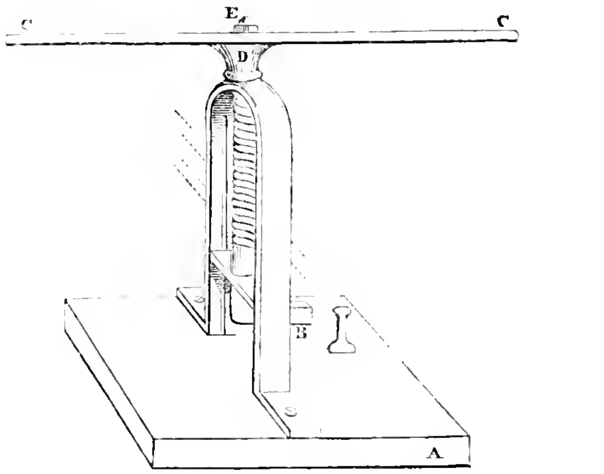
"The break lever K, figs. 1 and 2, moves inside of, and is suspended when out of action on, a projecting stud, inserted in the vertical spindle G. W is a weight to increase its power, or a spring to press upon the lever may be employed for the same purpose; this lever is fixed upon a short spindle passing horizontally through, and having its bearings in two plates, K, bolted to the engine frame, one within and the other without; of these, the outside one only, *k*, is visible in fig. 2, and upon the inside end of the spindle is fixed a short cross lever, the position and form of which is shown by figs. 8 and 9. The ends of this lever, K, bear upon the breaks *h h*, when the lever K is down, but each end has two cross pins under the straps *l l*, secured and screwed on the breaks for lifting them off the wheels on raising the lever K. These breaks are brought into action by lowering the lever K, occasioned by the removal of the supporting stud on the vertical spindle G, which is effected when that spindle is turned by the crank lever H, coming into contact with the slants L L in the manner before described."

The machinery last described is stated to be as applicable to the breaks, attached to the different carriages in a train, as to the locomotive engine; "especially upon such breaks by means of a spindle similar to the vertical spindle G, in the manner before described."

The lever R that brings the stationary apparatus into use may be worked by hand by any of the policemen stationed on the line, or other person appointed for the purpose.

The claim of the patentee is as follows:—"I declare that though I have specified under this head those contrivances and arrangements by which I think the objects in view may be best accomplished, and mentioned also certain contrivances which may be substituted for some of those so preferred by me, I declare that I do not confine myself to the precise arrangement and construction of the parts shown, as they may be varied under different circumstances without departing from the nature of my invention, but I claim a right to all variations and modifications of the same, and to all substitutions of equivalent means, either in whole or in part, by which the like effects may in the same general way be produced. And I declare, that what I claim generally is the addition to railway engines and carriages of such a combination or system of levers connected with the steam cylinders, alarums, and breaks, that being acted on in the direction of the line of motion, they shall simultaneously, or nearly so, shut off the steam, sound the alarums, and bring the breaks down on the wheels, and also the fixing to or placing on railways of an apparatus such as that before described in such a position that it can be made to act on the said levers in the direction of the line of motion, (by some projected part or parts thereof) without the agency, and independently of, the will of the engine-driver, guard, or other person or persons on the engine or train required to be stopped. And I claim both of the mechanical means, or system of means, last herein generally claimed, whether used together or used separately, that is to say, whether both are used together as I have described, or one of them only in combination with some other and wholly different means, or system of means, from that which I have specificed."

THE PLATE-LAYER'S SCREW.



Sir—If the above rough sketch of an instrument for lifting the rails, &c. on a railway, for the purpose of repairs, be thought of any service to you or others, for whose assistance it was contrived, (the platelayer), you are at liberty to use it in any way that you may consider it deserves. The instrument is now generally used among the platelayers on the "Great North of England Railway," near York, and is found to answer the purpose exceedingly well. The bottom A, is inserted sufficiently below the bottom of the rail until the claw B, can be applied under the rail, when the instrument is screwed up by the handle C C, lifting the rail and blocks at the same time, when high enough, the plate-layer or repairer commences beating the under side of the block solid. The female screw is in the base of the cross lever at D.

Your's, &c. M. Q.

York, April 9, 1841.

THE ARCHITECTURE OF LIVERPOOL.

Sir—In the outset of my remarks on this subject I avowed my intention of preserving, to the best of my ability, a spirit of candour and impartiality; and I should feel that I was very far from acting up to this pledge did I not endeavour to make the best amends in my power for any injury or injustice which, however unintentionally, may have been done to the works noticed, or their authors. Overlooking under the circumstances, the acrimony of expression employed by Mr. Corbett, in his letter published in your last number, and giving, as I feel bound to do, the fullest credit to his disclaimer of having taken any unfair advantage in carrying out his design for the North and South Wales Bank, by examining those of his competitors, I claim from him credit for equal sincerity, when I declare that no idea was ever farther from my mind than that of sheltering myself under a saving clause, for the purpose of asserting any thing of which I doubted the truth. I further assure him that it gives me unfeigned pleasure to find him so entirely denying the charge, and that I sincerely regret having given publicity to such an imputation, which however, I must in justice to myself be permitted to say, would never have been the case had not the report obtained such general credence among those interested in the matter, as left me, as I then thought, no ground for doubting its truth. As regards the committee, the case is by no means so clear; and without intending in any way to connect Mr. Corbett's name with proceedings of which he professes entire ignorance, I maintain that judging from his building as executed, and from the designs he submitted in two later competitions in this town, as compared with the known ability of several of the competing architects, it is difficult to conceive how, except by the exercise of some private influence, the decision of the committee should have been unanimous in his favour. Competition committees, however, are in their movements among the most eccentric and inexplicable of bodies, and it is vain to attempt arguing on their sources of action by the rules commonly applicable to organized matter.—With respect to the limits of cost, and the time the plans were in the hands of the committee, I spoke to the best of my knowledge and recollection; and still think that part of the designs at least were six weeks in their possession, and that the sum of 5000*l.* was *named* as the proposed amount of expenditure, but I suppose from Mr. C.'s plain assertion, not so advertised.—My mistake as to the position of the back wall of the portico, arose from the view obtained through the open doorway, of the wall of the vestibule next the bank; and such is the confusion of lines, arising from the number of features which are crowded into this narrow space, when seen in passing close to the front, as was the case with myself, that the most unequivocal impression remained on my mind that the case was as I stated it; and I was not singular in this idea. The door is now I see in its place, and this deception is corrected; but the pediment, which, as Mr. Corbett will perceive on reference, I mentioned as *principally* marking the obliquity of plan, remains unalterable, and its effect in this respect is most undeniable, as any one may prove by trial with a block model. I hold my first opinion as to the waste of valuable space caused by the use of columns and pilasters; and though the privilege of advancing the bases a few inches over the footway had at the time slipped my memory, the fact is certain that *room is sacrificed*, and the public thoroughfare contracted, for the purpose of employing a mode of decoration most unsuitable for a building of such proportions, and by this means cutting it up into a series of narrow strips, into which the necessary openings must be crammed as they best may.—If Mr. Corbett acknowledges, as by his silence on that point he in substance does, that the sketches sent you are fair representations of the proportions of his building, I may safely leave the question of its merit in point of design to the judgment of your readers; and trusting that the "judicious Eder," and the "many" admirers mentioned by Mr. C. may long remain the sole advocates of such a style as the Bank exemplifies.

I remain, Sir, your's obcdiently,

H.

Liverpool, April 12, 1841.

ON THE EMPLOYMENT OF MILITARY ENGINEERS.

Sir—The perusal of the article in your last number on the subject of the employment of military engineers in positions to dictate to the civil professional practitioners, has called into expression my own long dormant feelings upon a very similar subject.

It has been my lot to have had the means of observing, rather intimately, the working of the civil engineering and architectural operations of the Ordnance and Admiralty departments of the public service, upon which subject I beg permission to offer a few remarks.

It is well known that a set of young gentlemen dignified with all the notions of embryo-officers, are drilled through what is called a "*course of civil architecture*," under the auspices of a *colonel* at the Royal Military College at Woolwich. When lectured through this educational course, under the instruction of their Military Commandant, and made very clever in copying drawings, they obtain their Lieutenant's commission, and become at once, and as a matter of course, endowed with the necessary qualifications for designing and executing all the details of the civil engineer and architect's profession. They are stationed at an out-post under a staff of colonels and captains, and are expected to make drawings, measure artificers work, abstract, price, and enter into all the minutiæ of a civilians practice. They pretend to great efficiency and usefulness, and are very apt in signing at full length their names and designations to the designs, &c. of which they are supposed to be the authors. But it happens that to every station there is attached an humble ill-paid individual usually emanating from the carpenter's bench, and rising through the grade of Foreman, to what is called the Clerk of Works. He and he alone is really the designer, the estimator, and measurer, the every thing but the signer. He, though generally himself most incompetent to perform the lowest duties of the architect's profession, is yet sufficiently in advance of his military masters to do all the work for which they get the credit. With all the innate idleness of military men, added to a professional pride which raises them above the indignities of actual practice—with no inducement to, and no necessity for, that incessant application to details which can alone impart information and lay the ground work of professional acquirement, they saunter through the subordinate ranks, till at once getting the rank of colonel of engineers, they are fit for any thing!

Barristers of 20 years standing, whether they ever held a brief or not, are duly qualified for most things, but a colonel of engineers beats them hollow, their very rank endows them with that excellency of skill, that pre-eminence of knowledge, that loftiness of science which marks them as the class by which not only the public departments connected with civil engineering and architecture are to be controlled, but from which commissionerships of all sorts are to be formed to discipline—to dictate to—and to degrade—men, whose individual energies have done more to elevate their country in the scale of nations, and whose efforts have been more successful in developing its resources, and in promoting the industriel happiness of its people, than those of any other body, of whatever class, or of whatever pursuit.

At this moment we have a captain of engineers at the head of the architectural and civil engineering departments of the Admiralty, a man who alone and unassisted is incompetent to execute with decency the most ordinary architectural performance—a man who has only the most general smattering of architectural knowledge, who, if he had to pass an examination, with an attentive pupil of four years standing, would be disgraced; and yet this man is at the head of a department in which hundreds of thousands of the public money are annually expended.

But perhaps it will be said hé is only the director-general, in whom a tact in the management of business, and a soundness of judgment upon ordinary subjects, is more important than the knowledge of professional detail. He who knows most of his profession most highly, values this description of knowledge—but be this as it may, let us see who are the working men. At nearly every dockyard there is stationed a resident lieutenant or captain of engineers, one of the class before alluded to, who lords it over a few foremen, and perhaps a clerk of the works. These men have no practical acquaintance with the value of materials or the cost of labour, their knowledge is confined to the experience of government work, and they are under the necessity of confiding in persons whose direct interest it is to abuse their confidence, and to make the most advantageous bargains for themselves. If competition be had recourse to, it is well known that contractors who have to deal with men ignorant of the usages of private business, and from that ignorance open to abuse, have a thousand ways of taking advantages which the experienced practitioner would readily detect.

Why should not these military architects and engineers be called upon to submit to public examination before their appointment? I know of one of these functionaries who, when first appointed to conduct works amounting to from 12 to 20,000*l.* a year, was unacquainted with the commonest professional terms. The candidates for country engineers in Ireland have to pass a severe examination. The candidates for private employment are constantly subject to the test of severe competition, and why is the same course not adopted with respect to these mighty men? Does their rank oppose so insufferable an indignity? or does it not signify whether they be qualified or not?

Z

since if they fail, if they squander the public money, its *only* the public who suffer, and nobody feels it.

It may be asked what is the practical evil of all this? Some of the evils which I have observed are, that the director of works puts himself under obligations to the more experienced builder for the information which he lacks; deplorably ignorant himself, he draws from him his ideas, and gets into the habit of *depending upon* the very man whom he should be in a position to *direct*. One result of this is, that money is wasted in useless strength, or in the adoption of expensive methods and expensive materials. The self-styled engineer feeling no confidence in his own knowledge, and desirous above all things to avoid the onus of a failure from want of strength, is induced to lavish expenditure in the attainment of security beyond all necessity, and even beyond all decency. And so our government works instead of deriving all the benefit of the experience of private undertakings, are usually conducted in a manner altogether in arrear of the knowledge of the times.

Instead of employing persons competent to design public works, and well acquainted with the most advantageous mode of getting them executed. If any matter demanding superior skill be required, such for instance as a swivel bridge (as was recently the case in the Plymouth Dockyard), a manufacturer is invited to submit his *design* and tender, and the work costs 40 per cent. more than it would if competition tenders had been called for upon a specific design. But who is to make that design? how is it to be had if the persons employed in the engineering department, whether chief or subordinates, are incompetent to its production? and if incompetent to such a work, how fit are they for the office which they hold?

How does it happen that these things are so? That the most competent man that can be found as the Surveyor of the Navy, whose office it is to construct ships, and to make drawings, and enter upon all the elaborate calculations required in such an important work, is *not* a profound mathematician, who having great mechanical skill, and having directed his entire education to that pursuit, is well informed upon all its manifold mysteries—*not* a practical ship builder who, having a scientific mind, and gifted with intelligence beyond his fellows, has attained the theoretical and mathematical knowledge which forms the necessary qualifications of an accomplished naval architect—*not* either of these, but a *Captain in the Navy*, a man who knows as well how to build a ship, as a prince does a palace, or an archbishop a cathedral. Many gentlemen who have always lived in good houses, and noted their conveniences or defects, fancy themselves very skilful in arranging the apartments of a mansion, and sufficiently knowing for all the measure of taste that they think necessary for its embellishment; they build after their own designs, and under their own management, and whether *they* find it out or not, all their friends discover that their deep solicitude for some darling "bijouterie" has spoiled their house, that they have sacrificed their comfort and their purse to their conceited notions: and yet the Captain in the navy has lived in a ship from his boyhood, has noted all its good or bad points, and is not he the man to build a ship? he may build and he may alter, and he may be very successful in attaining some one point of excellence, but at what cost? let the naval expenditure tell, and it *could* tell some very deplorable tales upon this subject; it could tell at what *cost* the country has progressed with the education of our Captain-Surveyor, what has been paid for his experience, and how dearly we ought to prize it. This, Sir, is part of a system which is overrunning all the departments of the public service, we are becoming a military-ridden people in matters essentially civil. Naval and military men hold together and assist each other to the degradation of all the branches of the civil service. Their rank is a passport every where, and gives them a position which is not readily yielded to civilians, of whatever merit: existing upon patronage, they nurse it and cherish it as their best friend, and whatever of it they have to disperse, they take good care that it shall flow into the prescribed channel of their own order.

I do not expect that writing upon this subject will be of much practical utility, and I hate agitation, but it is high time that some notice of so wide-spreading an evil against the profession which your Journal so ably upholds, should find a place in its columns. It is the more important that it should do so now, that we are told by the President of the Institution of Civil Engineers, that too many young men are crowding into the profession, which is overstocked with professors, while the field of their employment is diminishing. It may well indeed diminish, while the government departments overlooking the claims of men whose professional education has cost *them* seldom less than 1000*l*. are put aside by military pretenders, who after a few months dabbling in drawing, under the masters of the Royal College, are turned out finished, and fit for the best of every thing.

Verily I wish there were a tribunal at which these belted aspirants could take a tilt with *working men*. I would have them set alone, not even should the despised clerk of works lend his wonted and bashful glance—he should not only *sign* the design, but he should make it, and a very pretty business he would make of it.

Having brought my military professors into this predicament I am quite content to leave them there, and subscribe myself,

A Civilian.

RIVER SEVERN.

Report on the Proposed Improvement of the River Severn, between Gloucester and Stourport.

By William Cubitt, Civil Engineer.

The object of this report is to set forth the proposed plan and probable cost of the intended improvement in the navigation of the river Severn, from Gloucester to Stourport, agreeably to plans and sections lodged with the respective Clerks of the Peace, preparatory to an application to Parliament in the ensuing session for that purpose.

In its present state the river Severn abounds with shoals, which very much impede the navigation, so as to render it impossible for the vessels which navigate it to proceed with full cargoes, or in a long continued drought to proceed along the river at all, to the manifest disadvantage of all that portion of the public which has any interest in or dependence upon the navigation of the river Severn.

The object of the proposed plan is to obviate these difficulties, and to obtain a minimum depth at any time of not less than six feet of water in all parts of the navigation between the entrance lock of the Gloucester and Berkeley Canal, at Gloucester, to the entrance lock of the Staffordshire and Worcestershire Canal, at Stourport, and upon such principle as will in no wise interfere with the due and proper drainage of the adjoining lands, or the discharge of the flood water of the river as at present, except insomuch as both may be improved and facilitated by the measure.

The means by which this improvement is to be carried into effect, is by what are technically termed weirs and locks, of which there will be five of each between Gloucester and Stourport.

The effect of the weirs or dams in the river is to divide the whole fall of the low summer water between Stourport and Gloucester, into five steps or falls, and by a side cut or short canal (with a lock therein) round or past the side of the weir, the navigation is carried on in the same manner as in an artificial canal, whilst the river passes off over the weir at a depth or thickness proportioned to the quantity of water coming down, and the weir is so contrived as to height, length, and position, that whilst it will never let out the water of the river below the fixed navigable depth in time of short water, it will nevertheless afford a greater capacity for the escape of flood water than at present obtained in the same place; and as all the shoals in the river between the weirs are to be dredged out to make a uniform navigable channel, it must be evident that the capacity of the river for the discharge of floods must be increased and improved, whilst through the same means the low summer water will be prevented from running off below its present level at the foot of each weir; and from the low water channel being deepened at the shoals, the exit of the drainage water will be improved also, whilst the navigation will be at all times available whether it be drought or flood.

The total fall of the river at summer water, from Stourport to the entrance of the Gloucester and Berkeley Canal, is thirty-two feet in a total distance of forty-two miles, of which the lower portion from Gloucester to Upton Ham, (the site of the first weir), being a distance of eighteen and a half miles, the fall is only four feet, a quantity but little more than sufficient to carry off the water in the ordinary state of the river, the whole of which distance being subject to the influence of the tides, no weir or locks will be required within these limits, (that is, from the Upton weir downwards), and no other operations than dredging and regulating the breadth of the low water channel, to obtain the requisite navigable depth, will be necessary; and it may be further observed, that no dredging or deepening of the channel will be done on the Gloucester branch of the river below the entrance of the Gloucester and Berkeley Canal, or on the Maisemore branch lower down than the entrance lock to the Herefordshire Canal, and to no greater depth than the sill of that lock, and of sufficient breadth to admit the boats which navigate it to pass to and from that canal and the river at the Upper Parting respectively; by which means, and leaving untouched the remaining portion of both branches below the entrance to the Berkeley and the Hereford Canals respectively, it must be evident that no alteration will be made in the height or level of the surface water of the river up to the first weir in a distance of eighteen and a half miles above Gloucester; nor is it intended or required by the present proposition for obtaining a six feet navigation to erect any weirs or locks, or to do any works that may affect the height or level of the river below the weir at Upton Ham, or in any way to affect, alter, or interfere with the adjoining lands in relation to the river as at present existing.

Proceeding upwards, the next weir and lock are at Worcester, just below the entrance lock at the Birmingham and Worcester Canal, at Diglis, a point twenty-nine miles up the river from Gloucester; the third weir and lock will be Bevere Islands, four miles above Worcester, at a place where the river has two channels, in one of which will be placed the weir, and in the other the lock, by which the necessity for an artificial canal or side cut will be avoided.

the fourth weir and lock will be just above Holt Bridge, three miles and three quarters above No. 3; and the fifth and last, at Lincomb Hill, four miles and a quarter above No. 4, or just forty-one miles from the entrance to the Gloucester and Berkeley Canal at Gloucester, and one mile and a quarter below Stourport Bridge, making a total distance of forty-two miles and a quarter for the improvement of the river, and making a minimum navigable depth of six feet over the lock sills, without raising the usual summer height of the water in the river at the tails of any of the locks and weirs, or causing any obstruction to the passage of flood waters.

Such is the mode by which it is proposed to improve the navigation of the river Severn, and which may be more fully understood by a perusal of the plans and sections as deposited with the Clerks of the Peace, in which the details of the measure, as required by the standing orders of Parliament, are clearly and correctly laid down.

Adverting, however, to a meeting of the land proprietors along the Lower Severn, (viz. from Worcester downwards) held at Tewkesbury, on the 16th December, and a meeting of the parties interested in the navigation of the river Severn, held at Gloucester, in the evening of the same day, at both of which I had the honour of attending, and giving such verbal explanations of this measure as were then and there required; and with reference also to certain resolutions which were passed at those meetings, and at a subsequent meeting of the committee of landowners, to the purport generally of requiring more definite information in writing from the promoters of this measure, as to the nature and extent of the proposed works, and every particular connected with the undertaking, as regards not only the nature of the works, but also the constitution of the Association for carrying them into effect, and the amount of tolls to be levied for defraying the cost, and maintaining the undertaking, &c., it may be observed, that there are some points, perhaps, out of my province to answer.

In addition, therefore, to what has been explained already with regard to the nature of the works, it may be satisfactory to the parties making inquiries at the meetings above stated to state,

1stly. That there is no intention of taking land without consent of owners, along or on either side of the river, except at those parts shown on the plan as the situations of the locks and weirs.

2dly. That the weirs will be solid weirs, placed very obliquely across the river, and of such length that (with the requisite widening of the river at the spot) there will be a greater water way on any cross section of the river at the weir after its erection than before.

3dly. That the height of the weirs, as shown on the sections, will not raise the water in short-water seasons above the present summer level at the site of each weir next above respectively; and the depth of water to be maintained by dredging, is a clear six feet below a horizontal line extending up the river from the top of each weir respectively.

4thly. The locks are proposed to be not less than one hundred feet clear length within the chambers, nor more than twenty feet in clear width, with six feet water over the sills in low summer water.

5thly. The estimated cost of the works from Gloucester to Stourport is £150,000, of which, as nearly as may be, one moiety will be expended between Gloucester and Worcester, on a distance of between twenty-nine and thirty miles, and the other moiety between Worcester and Stourport, a distance of thirteen miles, or thereabouts.

6thly. As regards the tolls to be imposed, to meet the above expenditure, maintain the works, defray the current charges of management, and (as should be contemplated) raise a fund to pay off the original cost in course of time,—that is probably a question more suited to the committee of management than the engineer; the question, however, is in very narrow limits, and assuming the minimum annual amount necessary to be raised for the above purposes, of interest, management, and maintenance, to be £10,000, and which, in my judgment, would be but just sufficient without paying off any capital, it follows that the amount of tolls per ton must depend upon the quantity conveyed along the river both ways, between the three principal points (Gloucester, Stourport, and Worcester) respectively. Taking, therefore, the charge per ton from Stourport to Gloucester to be double that from Worcester to Gloucester, and assuming the minimum charge for the long length to be sixpence per ton for the whole distance, it will require 270,000 tons between Stourport and Gloucester, at sixpence per ton, and 260,000 tons between Worcester and the other two points respectively, at threepence per ton, to raise £10,000. But as various contingencies may arise tending to increase the annual cost, or to diminish the amount of tonnage; and as a liquidation of the first cost ought never to be lost sight of, I strongly recommend that powers should be taken to fix a higher toll than sixpence and threepence per ton for the whole and half distances respectively, and am of opinion that one shilling per ton for the whole distance, and sixpence per ton for the Worcester half either way, should be fixed as a maximum, beyond which the commissioners should not have the power to charge, and that sixpence and threepence should be the minimum below which the tolls should not be reduced till such time as the first cost of the works be either funded or paid off; and if provision were made that an additional sum were funded before the tolls be reduced, the interest of which would serve for wear, tear, and management, the river in its improved state might be looked forward to as becoming in time a *free navigation*.

7thly. Touching the constitution of the managing body, all I can offer on that head is an opinion many times urged on other parties when attempting to form a company for improving the navigation of the Severn, viz. that the improvement of this navigation should be carried into effect by commissioners under an act of Parliament, as a public rather than a private measure, and in such manner that the profit or emolument to be derived from the measure, should eventually go towards the reduction of tolls, and rendering the navigation free instead of being made private gain or individual speculation.

W. Cubitt.

London,
January 5, 1841.

Report to the Committee of Management of the Gloucester and Berkeley Canal, by W. Clegram, Engineer.

Gentlemen—In compliance with your instructions, I have carefully examined the plans now proposed for improving the navigation of the River Severn, from Gloucester to Stourport; and with the explanations which I have received from Mr. Cubitt, the Engineer, by whom the works are projected, I am enabled to report my opinion upon the subject.

It is most certain that the interests of the Gloucester and Berkeley Canal Company are deeply involved in the measure—few have more to gain, or more to lose, from the success or failure of it, than the Canal Company; and instead of confining my attention simply to the engineering department, I have endeavoured to take a general view of the whole subject, in order to ascertain what are likely to be its effects upon the welfare of the canal.

To come to a right understanding of the matter, it should be known, what are the existing inconveniences in the navigation of the river, and what would be a sufficient remedy

The obstructions to the *free* navigation of the Severn, arise from two causes, viz.: from too *great* a quantity of water in time of floods, and from too *small* a quantity in the summer season. The former is without a remedy. And it is to supply the deficiency of the latter that the plans of the "Severn Navigation Improvement Association," are proposed as a remedy. This deficiency of water is felt on an average, during three months in the year; and it is the opinion of nearly all the traders on the river, that, if a depth of four feet, or four feet six inches of water could be maintained throughout this period of the year, it would fully meet the wants of the trade.

To remedy these impediments, and meet these requirements of the trade, the "Severn Navigation Improvement Association" propose to obtain a depth of water in the river, throughout the dry summer weather, of from seven feet, to seven feet six inches between Gloucester and Worcester, and a depth of seven feet between Worcester and Stourport, by plans so nearly similar to those last proposed, and described in my report of the 12th December, 1837, that I need not here recapitulate the particulars, but merely state, that, it is to be effected by dredging away the shoals in the river between Gloucester and the first dam, which is situated just below Upton-upon-Severn, about eighteen miles and a half above Gloucester. This dam will carry the proposed depth to Worcester; and between Worcester and Stourport there are to be four other dams to give the depth of water to Stourport. The dams are to be passed by side cuts and locks. The locks are to be 100 feet long, 20 feet wide, and with six feet of water over their sills. The dams are to be solid, entirely across the river; but placed so obliquely across the stream as to offer the least possible obstruction to the passage of the flood waters. The entire cost is estimated at 150,000*l.* The maximum toll is proposed to be 6*d.* per ton from Gloucester to Worcester, and 6*d.* per ton from Worcester to Stourport; or 1*s.* per ton for the whole distance; to be equally levied upon the goods conveyed by all classes and description of vessels throughout the whole year. And the works, in execution and subsequent management, are to be placed under the control of Public Commissioners.

This is the plan proposed; and I cannot say that the opinion I have formerly expressed on the engineering defects of a former and similar plan is in the least degree altered with respect to this—for I consider it, as I did the other, inapplicable to any river similarly constituted with the Severn. For from the mountainous rise of the river—its rapid and precipitous course throughout a considerable portion of its length—from the accumulated waters of several rivers being poured into it, and thus being the drain of a very large extent of country,—its waters are not only highly charged with silt held in suspension in them, but vast quantities of gravel and heavy materials are brought down, and rolled over the bed of the river in a continuous stream. Any interference therefore (as would be the case by the plan proposed) with the bed of the river, that would destroy its natural powers of cleansing itself, must necessarily entail a heavy and constant expense to provide artificial means to get rid of the accumulations—for with the tidal deposits on the one hand, and the land flood deposits on the other the accumulations will be very great. I have not documents by me to refer to, but I believe the late celebrated Mr. Telford, when employed about the year 1824 or 1825 to offer some plan for the improvement of the navigation of the Severn, gave a similar opinion to my own. I know that he recommended the formation of a canal between Gloucester and Worcester, at a cost of 200,000*l.* which he was not likely to have done, had he considered the river capable of economical and permanent improvement.

But setting aside these engineering difficulties, there can be no doubt that the proposed works are on a much larger scale than is needed. The depth of water over the outer sill of the Gloucester and Berkeley Canal Lock at Gloucester, during the low summer water, being from 4 feet, to 4 feet 6 inches only, is quite the index of what the depth should be in the river; for it is clear, that vessels loading in the canal for the river, would not be loaded to a greater depth than that of the water over the sill of the lock through which they must pass; nor would vessels coming down the river at this season (however great the depth of water that might be obtained in the river) be loaded to a greater depth, and thus be subjected to the delay and inconvenience of the transhipment of a part of their cargoes before they could enter the canal. As a proof that the trade requires no greater depth than this, I may mention, that it is indeed a rare case for even the largest trows to be loaded, at any season of the year, to a greater depth than 4 feet, or 4 feet 6 inches, for navigating the river above Gloucester; and if it be said that this arises from the want of water, I would reply, that if it were more convenient or economical to sail these craft at a greater depth, it would surely be done during the nine months of the year when the depth of water is ample for it. I feel satisfied that if a depth of 5 feet, or 5 feet 6 inches at the most, of water, could be obtained, and maintained during these three months of the year, it would, for the considerations above set forth, be found fully sufficient. In this case, the whole of the works, the dredging, the dams, the locks, the cuts, the equalization of the area of the channel, all might be proportionately diminished, and performed at a considerably less cost. In dredging alone, about 150,000 cubic yards might be saved, (being upwards of one-half the whole quantity at the 7 feet 6 inches depth,) and the annual cost of management and maintenance would be much lessened; and I think it probable, that this diminished plan might be done and upheld at a cost that would not require the imposition of more than an equivalent toll for the benefit conferred upon the trade. The toll necessary to pay the interest on the money to be expended in carrying out the larger plans of the "Severn Navigation Improvement Association," and in upholding the works, I should fear would press very heavily upon the trade, especially as it would be levied throughout the year upon all classes of vessels, the greater part of which, from their light draft of water, would derive a comparatively small advantage from the measure.

These are weighty considerations for the Canal Company; and if it be, as I have frequently heard it advocated at your board when any suggestion has been made to raise the tonnages of the canal, that the smallest additional imposition of toll on those articles which form the bulk of the trade upon the canal would be ruinous to it, the same effect would result from the imposition of any toll for navigating the river, if it exceeded the limit of the loss sustained by the trade from the impediments existing in the navigation of the river.

The only other points that I have to allude to are—1st, that the notices of the intended application to Parliament are for power to improve the river from the *Lower Parting* upwards, whereas the deposited section shows an interference with the river only as low down as the lock of the Gloucester and Berkeley Canal in one branch, and the lock of the Hereford and Gloucester Canal in the other branch of the river. At the meeting with the promoters of the measure on the 16th of December last, an explanation of this discrepancy was asked, and it was replied that there was no intention to touch the river below the points above named, neither would they obtain power in their Act to do so. Secondly, the removal of the Maisemore shoal, in the Over branch of the river, to the depth shown in the section. This shoal, it was pledged, should only be removed to the depth and width necessary to accommodate the vessels navigating the Hereford and Gloucester Canal. It is most important to the interests of your canal that the parties should be kept to this; for any interference with the shoals between your lock and the Lower Parting, and with the shoals in the other branch of the river, would seriously diminish the depth of water in the Gloucester branch of the river, and consequently over the sill of your lock, and ultimately render it necessary to place the sill at a lower level, which, if ever needed, will be a work of considerable difficulty and expense.

For the reasons above stated, I can neither approve the *mode* by which it is proposed to improve the navigation, nor the *extent* to which that improvement is proposed to be carried; believing the mode inapplicable to the character of the river, and the extent more than is required by the trade.

W. Clegram.

Saul Lodge, 5th January, 1841.

Report addressed to the Committee of the Gloucester and Berkeley Canal Company, on a Bill now in Parliament for the Improvement of the River Severn. By James Walker, LL.D., F.R.S., L. & E., Civil Engineer.

Gentlemen—Since I received your resolutions and the communications from Mr. Brickwood, I have given my attention to the plans and sections which accompany the application to Parliament for the improvement of the river Severn, with Mr. Cubitt's report in explanation of the scheme and its advantages, and also Mr. Clegram's report to you, with other documents and papers on the subject.

In December, 1836, Mr. Rhodes, the engineer to the then proposed Severn Improvement Company, accompanied Mr. Cubitt and me on a view of the river. There had been a high flood ten days before, and at the time of our view the water was from eight to ten feet above the summer level. Ever since I received such recent instructions as I felt justified to act upon, the floods have been still higher, so that I have not had the opportunity of seeing the river in its short-water or summer state which would have been desirable; and my report must be taken, with allowances for this disadvantage, as to knowledge of facts and otherwise.

Mr. Cubitt's Plan.—Mr. Cubitt's plan is well described in his report. It differs from that of Mr. Rhodes in his plan first deposited, when a ship communication to Worcester was intended, in leaving out the weir and works Mr. Rhodes proposed near Gloucester; in placing the first weir, that near Upton, about a mile higher up the river than Mr. Rhodes at one time proposed, and about three miles lower than Mr. Rhodes's last proposal, as I understood it from himself*: in placing a lock and weir below Worcester, and below the entrance of the Birmingham and Worcester Canal, instead of above that entrance; in placing the uppermost lock, that nearest Stourport, in the river, and the weir in the new cut, the reverse of Mr. Rhodes's plan; in increasing the length of all locks above Worcester from 90 to 100 feet, and diminishing the width from 24 to 20 feet. I observe also that the works are now to be executed, not by a Company, but an Association, and if this word be, as respects the objects, synonymous with Trust or Commission, I think the change of character a decided improvement, for the idea of locking up the Severn in the hands of a joint stock company always appeared to me very objectionable.

Trade of the River Severn.—The River Severn, from its position in reference to the Bristol Channel, from the very great length for which it is navigable, from the numerous canals that connect with it, and which supply the wants, and take off the natural products and manufactures of several of the most densely inhabited and richest counties, and from the great extent of country of which it is the great drain, is in point of importance inferior to scarcely any river in the kingdom. Below Gloucester the river suddenly spreads out to a great width, and partakes more of the character of an estuary, consisting of sandbanks and shallow, shifting, tortuous channels, and a lift of tide that is scarcely perceptible at neaps.

Hence, in its natural state, the Severn was not, without great danger and delay, navigable for many miles below Gloucester, but for the smallest description of vessels; Bristol was, in fact, the port of Gloucester. The Gloucester and Berkeley Ship Canal, which was begun by individual subscriptions in 1794, and which, through want of funds, might, but for the liberal loans from the Commissioners for the Loan of Exchequer Bills for Public Works, have been a ruin at this time, was opened in 1827, and has removed the above evil as high as Gloucester. Ships of very heavy burthen, say 500 to 600 tons register tonnage, are now docked close to the city, and an impetus has been given to the trade of the town and of this portion of the kingdom. In this dock by far the greater part of the ascending and descending inland trade is transhipped into or from canal boats and barges—the remainder is conveyed in Trows, which load chiefly at Bristol, pass through the Gloucester Canal, and go up to Worcester, thirty miles, or to Stourport, which is twelve miles higher.

Proposed Improvements.—It is upon the portion of the river between Gloucester and Stourport, that the improvements are now proposed, and notwithstanding my limited knowledge, I feel justified in saying, that whether as respects navigation or drainage, this river has been most greviously neglected, that it is capable of improvements, and that it ought to be improved. At present we have a river of the importance I have named, upon portions of which the track-path (if it deserve the name) is covered with water, so as to be impassable whenever there is any flood. In short-water time, again, the shoals are such, in many places, some even below Worcester, that a canal boat of 24 tons burthen, and drawing under four feet, the great trade of the river, cannot make certain of getting over them, but is liable to considerable delay. These shoals are local, and appear to consist of material which might be removed, and being removed, and the width regulated, would not be likely to return, as is proved by the deeper water, above and below the shoals; but even this does not appear to have been attempted.

Expediency of Improving.—On the expediency of some improvement there ought not, therefore, as I think, to be any difference of opinion. The questions are, to what extent, in what manner, and how the trade is to be taxed to secure the repayment of the cost of the necessary works? for without good security, either the funds will not be obtained to do what is required, or the terms will be unfavourable, for which the trade will, in the end have to pay. The idea of paying any thing upon a hitherto free river may not be more agreeable than the payment of tolls upon turnpike roads; but if the expenditure be judicious, and the toll equitable, the traveller who pays has the greatest benefit.

Proposed Depth.—Mr. Clegram thinks the depth proposed by Mr. Cubitt greater than the vessels that now use the river require; and his observations on the particular nature of the trade are entitled to great attention. But it is also to be remembered, that the size and draught of a portion, at least, of the vessels, those that load in the river, are limited by the capability of the river; that half the number of Trows go up with half cargoes, caused, I presume, in part at least, through want of water; and that greater capability would probably give rise to vessels of greater burthen, which at present it would be imprudent to construct. Again, the facility of navigating vessels of less draught than the greatest depth, even canal boats, is increased by having a good depth of water. The floods also go off more rapidly; and thus both navigation and drainage are improved. It is to be remarked, also, that in fixing the level of the lock and weir, which cannot afterwards be increased, Mr. Cubitt is obliged at once to calculate on his ultimate minimum summer depth. Therefore, although the depth proposed by Mr. Cubitt may be too much to execute at first, I think that nothing particularly below Worcester, ought to be done which will prevent the depth he proposes, when there appear occasion and funds for it. The argument, that the upper lock of the Gloucester and Berkeley Canal has only four feet to four feet six inches in times of drought, is good to an extent only, and is a question of inconvenience against expense. A lock of greater size might, I presume, be made, should the trade justify such an expenditure.

Stourport to Worcester. Effect of Weirs.—I also think that, from the inclination of the river, and the nature of the channel, there is probably no better way of improving the navigation between Stourport and Worcester than by means of locks and dams. In saying this, I claim allowance for the limited extent of my information; and certainly, to dispense with the dams altogether, or even partially, would, if practicable, be desirable. Mr. Clegram's idea is that a canal from Worcester to Stourport is practicable, and would be preferable to dams.

Objection to Solid Weirs.—Thus far, and it is a great part of the way, I agree with Mr. Cubitt; but I cannot at all see how, if the dams or weirs are to be solid, as described, without flood-gates or even waste-boards, neither of which are named, they are not to prejudice the drainage, in place of improving it. If made very oblique across the stream, as proposed, their length will no doubt be increased; and with the same depth over the dams, the quantity passed over will be proportioned to the length. But the principal effect of lengthening the weirs will be to decrease the height of the water running over them, and not so much to increase the cubic quantity: for the quantity that reaches the weirs, or the depth at the weirs, is dependent on the direct cross-section (the width and depth) and the velocity above the weirs (that is, higher up the river), than where they are placed; and there

* I extract this from a note made at the time, but I am informed that Mr. Rhodes's plan (previously deposited) shows the weir in the lower situation.

is, I think, no doubt that placing solid dams at intervals across the stream, whether directly or obliquely, and from five to eleven feet above the present bottom of the river will diminish the velocity of that portion of the water which is below the level of the weirs, and near them, and of the whole descending column for a very considerable way up the river; and that in this length so interfered with, particularly near the weirs, first the water will be kept back, then a deposit will take place, which will diminish the depth, and therefore raise the surface of the water and increase the floods. The bed of the river will, in fact, be raised, unless kept down by constant dredging. But, even with dredging, the height of the surface of the water will be raised, independently of the bottom. When Mr. Cubitt says, "there will be a greater water-way on any cross-section at the weir after its erection than before," he either refers to length only, or to some particular depth over the weir at the time of some very extraordinary flood, because the sectional water-way can only be measured from the top of the weir, all under that part being, by the erection of the weir, taken from the area of the water-way. Without, I am sure the most remote intention, the position here stated is apt to mislead; and, independently of the above, I do not calculate on much good from the obliquity of the dams, unless the river be enlarged for a great length above them, so that the stream of the water may come at right angles nearly to the dam. Besides this, there can be no doubt that these permanent weirs will increase the difficulty, to say the least of any great future improvement to the drainage of the country above them. I do not mean to say that the dredging and deepening of other parts of the river will not diminish the effect of the obstruction, but the dams are so much higher than the shoals to be dredged, that I do not think they will by any means counteract the injurious effect, while the dredging without the solid dams would do as much good to drainage as to navigation.

Shropshire Navigation.—To the Shropshire navigation, also, from Ironbridge, the solid dams would be a great obstruction. The statement is, that these boats remain aground at Ironbridge during droughts, and until there is a fresh in the river, when they come down in fleets of twenty to thirty in number, making the passage of seventy miles to Gloucester in from eleven to sixteen hours: that there they unload their cargoes with the greatest dispatch, th t they may get up again before the water has gone down. I cannot see how, to this description of trade very serious delay by solid weirs is to be prevented, when each boat is to be locked down and up through five locks, independently of the risk of being carried over the weir when the velocity is considerable.

Can, then, the present delay during droughts be remedied, and yet these evils prevented? I think they can, even presuming dams to be necessary, by forming them not as solid weirs, but as opening gates, to be shut in times of drought only, but to remain open to the bottom of the river in times of flood, and whensoever there is abundance of water for navigation, so that both the flood waters and the trade may pass through the gates without interruption or delay by lockage. These gates need not be the whole width of the river, but the sides only, the space between the banks and the gates, should be furnished with sluice or draw-doors, to open so as to pass the floods, and to this there could not, as it appears to me, be any reasonable objection, unless the expense be such as to exceed the benefit, which when the importance of the navigation is considered, would not, I apprehend, be the case: but if it should be so, I still think that much good might be done by dredging the shoals, and contracting the width, where the too great width is the cause of the formation of the shoals, which, unless where the material is hard, will probably be found to be the case. In most cases, as appears upon the sections, the material of the shoals is too hard to be acted upon by the floods, and then the shoals, once dredged away, will not be likely to form again. Should not the experiment be made? It would be useful, even if dams were constructed afterwards. Undoubtedly the floods of the Severn, if more confined within their channel, would keep a large water-way open.

Worcester to Gloucester.—What I have yet said as to dams is confined to the part of the river above Worcester. Below that city the river assumes a different character, the depth is greater, and the quantity of low land which is liable to be flooded more extended. The entrance of the Birmingham and Worcester Canal is below Worcester: and I have been informed that two-thirds of the tonnage that goes above Gloucester does not go higher than Worcester. Hence, therefore, both as respects drainage and trade, an open unobstructed river between Gloucester and Worcester becomes much more important than above Worcester; the expense of a dam also, such as I have described, much greater, and I hope, and indeed think, it may be dispensed with. Mr. Rhodes designed his ship lock and weir at Saxon's Lode, 17½ miles above Gloucester, or one mile below Upton Ham, where Mr. Cubitt now proposes it: but, in consideration of interfering with the drainage of the district, he was induced, in his subsequent plan, as I understood him to say, to remove it up to Cleve's Lode, 23½ miles above Gloucester, or 5 miles above Mr. Cubitt's present site. Now, Worcester is only 6 miles above Cleve's Lode, or 11 miles above Upton Ham. In this length there is more than six feet in depth, excepting at the shoals, which do not appear more numerous than lower down the river, where the depth is proposed to be obtained by dredging. The average fall in the river, from Upton Ham to Worcester, being only 4½ inches per mile, I think there is little reason to apprehend a want of depth at the upper end, after such a deepening and regulating as will be required. If the excavated material were applied to raise the banks, the land would be less liable to be flooded, and the scour being confined in the channel of the river, would increase the depth. It will be understood that my objection as respects floods is confined to the space above the first weir—all below the weir will be improved by Mr. Cubitt's plan.

Thus, also, the objection made, reasonably as I think, to the inadequacy of one lock to pass the trade, would be obviated, as so large a proportion would stop at Worcester, short of the first lock.

Clyde.—The Severn here is in some respects different from the Clyde, but there is a similarity, and the good effects of not adopting Smeaton's plan of damming the river so as to secure a promised depth of 4 ft. 6 in. at Glasgow, at high-water neap tides, even after an act had been obtained for it, but of deepening and regulating, by which there is now 13 feet, has made that city what it now is, and has much increased the value of the low lands, which were more liable to be flooded than they now are. One would expect the Worcester, of all parties concerned, to be least the advocates for dams and locks between Gloucester, and their city, to limit the capability of their trade in the size and number of vessels; until, at least, it be proved that they cannot be dispensed with; and, whenever this is the case, the importance of having the gates constructed as I have described, to be shut in short-water times only, is greater here, on account of the extent of flooded land, than above Worcester. Whether referring to the extent of the trade, to the delay which will be consequent upon passing every thing through a lock, or to the drainage of the country, I think solid weirs objectionable; and if this be the case now, it will be much more so after the river is improved, if an increase of trade, with the introduction of steam-tugs, be the consequence, as is probable. A tug would take a whole fleet of boats or barges behind her. The Severn is at present far behind in the power applied to track the boats, being partly horse and partly human labour; and I decidedly think the solid weir will tend to perpetuate the slow system. Until steam be general, the towing paths ought to be raised and improved. They appear to lie in the hands of two joint stock companies, and the bill does not attempt to interfere with them, excepting at the proposed new cuts; but perhaps a great reform has taken place in their condition since 1836. The towing paths on the Clyde are entirely abandoned, every thing being done by steam-boats or steam-tugs.

Works above Worcester.—The dams above Worcester, as I propose them, would be more expensive than Mr. Cubitt's. I think it probable, supposing dams to be indispensable, that a smaller number might suffice, for the following reasons.—The average present summer inclination in the surface of the river above Worcester is 21½ inches per mile. Mr. Cubitt appears to suppose that, after the construction of the weirs this will be reduced to little more than one inch per mile, which I think very much under the mark, and therefore that the pen of the weirs will reach very much higher than he supposes, thus allowing sufficient depth for a greater length between the locks, which will be desirable. And here I may say, that I do not agree with Mr. Cubitt, when he states that, "if all below the entrance of the Gloucester and Berkeley Canal be left untouched, it is evident that no alteration will be made in the height of the water up to the first weir." On the contrary, every obstruction or shoal that is dredged in the whole length, tends to lower the water in the part of the river above it. The section of the stream being increased by the removal of the shoal, a less velocity, and therefore less slope in the surface of the water, is required for passing the descending water, and hence a sinking of the surface increasing upwards. This must be compensated for by greater dredging toward the upper end, to give the required depth. There ought not to be a difference of opinion on this point, and therefore either the expression does not convey Mr. Cubitt's meaning, or I have misunderstood it.

JAMES WALKER.

23, *Great George Street, Westminster,*
March, 1841.

THE TOMB OF THE GREAT CAPTAIN.

(From Dr. James Macauley Foreign Secretary of the Botanical Society, Edinburgh.)

Of the many historical monuments which are met with in the ancient city of Granada, one of the most interesting is the tomb of Gonsalvo of Cordova, the Great Captain. This tomb would in any other place have been a celebrated point of classic pilgrimage; but in a city containing the Alhambra and so many glorious remains of the Moslem empire in Europe, other objects of historic interest have been almost wholly overlooked by travellers. My attention was called to it by a note in my copy of Don Quixote, where it is said that "Gonsalvo toward the close of his life founded a monastery in the neighbourhood of Granada, and was buried in its church. His epitaph, which still remains there, is simple and grand; GONSALVUS FERDINANDUS A CORDOBA, DUX MAGNUS HISPANIARUM, GALLORUM ET TURCORUM TERROR." On making inquiry, I found that the tomb was not in the monastery he had founded, which was that of Cartuja, but in the chapel of the convent of San Geronimo. Of this magnificent edifice, the Nuncio Aldobrandini, while conversing in the Alhambra with Philip V., said that "he had seen nothing in Italy more great in architecture." Separating from this what may be due to the flattering courtesy of a foreigner, there is yet in the remark a good eulogium of the work, and a high testimony to the merit of the architect, the famous Diego de Siloe. He it was who also built the cathedral of Granada, which in magnificence and taste exceeds all the cathedrals of Spain, and may be ranked with the finest edifices in Europe. He spent thirty years in the construction of the convent of San Geronimo; a truly noble piece of architecture, whether we regard the grandeur of the design or the beauty of the details, and a work worthy of the high name which Diego de Siloe bears in the history of art in Spain. The place is at present used as a barrack for soldiers. The remains of Gonsalvo are in a vault in front of the altar in the chapel. This part of the building is in a most desolate and dismantled state, every vestige of decoration and ornament having been destroyed, and the very woodwork of the chapel having been torn down for firewood. What a contrast from the former condition of the place, when historians relate that the shrine was famous for its riches and splendour, and the walls were covered with trophies taken from the enemies of Spain, among which were two hundred banners and two royal standards taken by the Great Captain! The short epitaph formerly referred to, I was unable to find; but upon one of the flat stones on the floor near the altar I observed the following inscription:—

Gonzali Fernandez de Cordobâ,
qui propria virtute
Magni Ducis nomen
proprium sibi fecit,
Ossa,
perpetuæ tandem luci restituenda,
huic interea loculo condita sunt,
Gloriâ minime consepultâ.

The epitaph appeared to me to be happily expressed, and reminded me of the brief and fine eulogium of Cervantes, introduced at the place where the innkeeper brings to the curate and barber his library of three books, two of which were condemned to the flames, but the third was worthy of immortal honour, being the history of Gonzalvo Ferdinand, "el qual por sus muchas y grandes hazañas mereció ser llamado de todo el mundo Gran Capitan, renombre famoso y claro, y dél solo merecido." While our party were in the chapel, a number of the soldiers from the convent had followed us from curiosity, and wondered what we found to interest us in its bare and desolate aspect. In passing through Spain, the traveller at every step meets traces of its former glory and splendour, and cannot help contrasting these with the present degraded state of the country and people. The contrast came with new force to me while in the chapel of San Geronimo; recalling the brave veterans of the wars of Naples and Flanders, then the finest soldiers in Europe, and comparing them with the wretched troops of modern Spain, specimens of which were now gaping and jesting over the remains of the Great Captain.

PORTER AND CO'S PATENT ANCHORS.

One of the most interesting experiments, and one which cannot fail to prove of immense advantage to the navy, and the merchant service, took place on Monday in the presence of Captain Phipps Hornby, C.B., superintendent of Her Majesty's Dockyard, Woolwich, and a number of nautical gentlemen. One of Porter and Co.'s patent anchors having been previously placed on the testing frame, an immense power was applied by an hydraulic machine invented by Bramah and Son, and the anchor weighing 5 cwt. 2 qrs. 24 lb., which would have been considered safe according to the adopted test of $8\frac{3}{4}$ tons, actually sustained additional strains until it reached $20\frac{1}{3}$ tons before it gave way under the application of that immense power—nearly $2\frac{1}{2}$ times greater than would ever be required under ordinary circumstances. A second anchor, weighing 5 cwt., was afterwards placed on the testing frame, and the power having been applied, it sustained a strain of $21\frac{1}{2}$ tons, given by jerks, before it gave way, although it would have been considered perfectly safe if it had stood $8\frac{1}{4}$ tons. There was another anchor by the same patentee on the spot, of still larger dimensions, but the experiments with the other two were so satisfactory that it was not found necessary to prove its capabilities. It appears strange, and yet it is evidently the fact, that the more simple the construction of any article is, there is the greater certainty of its success. The principal difference betwixt this anchor of Porter and Co., and those at present in use, is a projection on the outside of the fluke, which enables it to catch hold of the most difficult ground, and ensures its obtaining a firm hold and double power by the upper fluke descending on the shank, and acting as a fulcrum in the most effectual manner. By the kindness of Captain Denham, of the Marine Surveyor's department, we have been enabled to give the following details of the advantages of this anchor.—"It is almost impossible to foul it. It bites quickly into the most stubborn ground. It holds on the shortest stay peak. It cannot well lodge on its stock-end. It presents no upper fluke to injure the vessel herself or others in shoal water. It cannot injure vessels' bows when hanging cock-bill, as merchant vessels find a convenient practice. It is not so likely to break off an arm or part in the shank as anchors with fixed flukes do, because the construction of these arms can be of continuous rod-iron, and the leverage is so much nearer the ring, owing to the pea of the upper ring closing upon the shank. It is a most convenient anchor for stowing on board, on a voyage, as the flukes can be easily separated, and passed into the hold; it can as easily be transported by two boats, when one would be distressed with the whole weight. Several of the officers who witnessed the experiments stated their intention of applying to the Admiralty for anchors on this construction, as they were so satisfied of their advantages."—*Times*.

INSTITUTION OF CIVIL ENGINEERS.

Jan. 12.—Joshua Field, V.P., in the Chair.

"*Remarks on the comparative advantages of long and short Connecting Rods, and long and short stroke Engines.*" By John Seaward, M. Inst. C. E.

The author commences the communication with a description of the engines first placed on board the Steam Frigate, "The Gorgon."

The engines are constructed on the principle of "direct action," that is, the power is communicated directly from the piston to the crank, without the intervention of side levers, and the other parts usually employed in the construction of marine engines; this is one leading feature. Another is, that the main shafts are placed directly over the centre of the cylinder; and as these shafts are carried by strong frames and wrought iron columns standing upon the cylinders, the force of the engines is confined between the cylinders and the frame, and thus isolated from the sides of the vessel. Other advantages accruing from this construction are, in the author's opinion, a saving of space and weight, the absence of the vibration resulting from the action of the side levers, and a more efficient application of motive power, arising from the simplicity of the construction and diminution of friction.

Two main objections have been urged against this system—1st, that the shortness of the connecting rod causes a loss of effect; and 2nd, that the shortness of the stroke is a disadvantageous application of the power of steam.

The arguments in support of these objections are combated at considerable length. With reference to the alleged loss of power by the use of the short connecting rod, it is argued, that as no arrangement of long or short rods or levers could create power; so no arrangement of similar parts could be productive of loss of power. A geometrical investigation of the force actually exerted on the crank by long and short connecting rods is then given, and the result deduced is, that by adding together the whole of the force exerted by the two kinds of connecting rods respectively, during one entire rotation, they both give the same actual amount; thus proving, that no loss arises from the use of the short connecting rod.

It is admitted, that there is some increase of friction on the journals of the connecting rod joints, but this occurs only at the extreme angles; some allowance is also to be made for the increased angular motion about the lower joints of the rod, but they are not collectively of sufficient importance to be considered as any objection in practice.

The calculations given are under the approval of Professor Airy, who thus expresses himself:—"The *greatest* force of the 'Gorgon' engines (when both cranks are below the horizontal line) is *greater* than the *greatest* force with common engines, but the *least* force is not less than the *least* force with common engines."

The whole power, in a complete revolution of the crank, is the same in both.

That a long stroke engine, under certain circumstances, may be more advantageously employed than a short one, is admitted; but considering the steam engine *per se*, it is argued, that the latter possesses no advantage over the former.

In two engines of equal power, equally well constructed, the length of the stroke being respectively eight feet and four feet, the cylinder of the latter having double the area of that of the former, making the same number of revolutions per minute, and having the steam passages and valves of the same area, it is clear, that the mechanical action of the steam must be identical, because the same volume of steam will produce an equal mechanical effect, whether it be introduced into a long narrow cylinder, or into a short wide one; setting aside the effect of working expansively, which, however, is not at all affected by the shortening of the cylinder: for it is just as practicable to shut off the steam at one-half, one-third, or one-fourth of the stroke of a short cylinder as of a long one.

The most essential differences between these two engines must be in the relative amount of friction, and of radiation of heat from the cylinders and passages.

In a well made engine four-fifths of the friction is due to the packings of the piston, air-pump bucket, and stuffing boxes, and about one-fifth to the gudgeons, crank pin, and other moving parts. The friction of the piston packing is as the circumference multiplied into the space through which the piston travels, and into the depth of the packing; therefore in a cylinder 30 inches diameter, 8 feet long, the friction of the packing will be as 24, while in a cylinder of 42·4 inches in diameter, 4 feet long, it will be only as 17.

The same train of reasoning is extended to the other moving parts, and shows that if the total friction in the short stroke be 100, that of the long stroke engine will be 123.

The radiation of heat from the cylinders will be as the relative areas of surface, which is less in the short stroke than in the long.

An examination of the comparative friction of the moving parts of steam engines is entered into; rules for computing, and tabular results are given; and the author concludes by observing, that although the relative dimensions selected as examples are uncommon in England, they are not so in America, where pistons of marine engines frequently travel at the rate of three hundred to four hundred feet per minute. It is contended that the speed of the piston is immaterial, provided the engine be well proportioned to the speed; at the same time bearing in mind that a slow speed will be more favourable for the easy and pleasant working of the engine, and for durability. The paramount objects to be aimed at in the construction of marine engines are, the greatest saving of fuel, space, and weight, and the durability of the machine; and as the question is not whether the stroke should be eight feet or four feet, but relates to a diminution from the present length of seven feet to probably six feet, it is contended that the form of the "Gorgon" engines offers considerable advantages in the points treated of, independently of the positive diminution of weight and space, which forms no part of the immediate inquiry.

A drawing of the "Gorgon" engines accompanied the communication.

"*Description of a Thirty-Ton Crane, erected on the Quay of Earl Grey's Dock, Dundee Harbour.*" By James Leslie, M. Inst. C.E.

The Crane is placed on a stone platform sixteen feet square, raised six feet above the level of the Quay, with its centre seven feet back from the Dock face; and as the sweep or radius is thirty-five feet to the perpendicular of the jib-sheave, the load is suspended twenty-eight or twenty-nine feet over the Dock (as the double or single purchase sheave is used). The height of the sheave above the level of the Quay is forty feet.

Instead of the framing revolving about a fixed post, as in the usual mode of construction, the post itself is connected with the framing, and turns with it, so that the strain may be always in the direction of the greatest strength.

To avoid the extra dimensions of the castings for the post, if it had been composed entirely of cast iron, and for facility in the construction, the parts of cast and wrought iron are so combined that the "push" is thrown upon the cast-iron abutting piece which is placed in front, while the back part, consisting of wrought-iron tension bars, bears the "pull." The two rings on the post are turned on the face and edges, and being bolted together form a fair surface for the friction rollers, while the back forms a rest for the tension bars.

These back tension bars are three inches wide by two and a half inches thick, each, forming an aggregate section of forty-five inches. They were all proved in the bent form in which they are used, by making fast the ends of each bar to cross heads held apart by two logs, and suspending a load of twenty-four tons from the elbow formed by the bend in the bar; this was calculated to be equivalent to a longitudinal strain of ninety tons. There are also two side tension bars, two inches square each, firmly sunk in the cast-iron block, and bolted to the top of the framing.

The post revolves within a cast-iron cylinder twenty-seven feet deep, five feet three inches diameter, with turned and bored water-tight joints. The whole is surrounded with masonry, bound together by strong iron hoops and diagonal tie bars passing through the fixed ring.

The jib is of oak two feet diameter in the middle, and twenty-one inches at the ends; the two wrought-iron jib stays are each three and a half inches diameter; the chain is of $1\frac{1}{4}$ inch iron. Eight men easily lift a weight of thirty tons, and by means of the horizontal wheel-work one man can turn it round.

The total weight of the castings, wrought-iron bars, chain, and brasses, is about fifty-nine tons.

The crane was made and erected by Mr. Borrie, of Dundee, from the designs and under the direction of the author.

The communication is accompanied by two elaborate working drawings, on a large scale, with details of the mode of construction.

"*A Refrigerator, or Machine for cooling Brewer's Wort.*" By Robert Davison, M. Inst. C.E.

The machine described in this paper was constructed for the purpose of ascertaining the most expeditious process for cooling wort, without deteriorating the quality of the liquor.

Two kinds of preliminary experiments were made, viz.—

1st. As to the rate of cooling by simple exposure to the atmosphere in the ordinary shallow vessel, having a superficial area of 420 square inches, the liquor being $1\frac{1}{2}$ inch deep.

2nd. As to the rate of cooling, under similar circumstances, with the assistance of air mechanically driven over the surface of the liquor at different velocities.

In both cases the loss by evaporation was noted.

The numerons experiments are detailed in a tabular form, whence may be selected three series, which will give the average relative results.

Wort cooled.	Naturally under Atmospheric Temperature, 75°.		1. By Blast at the rate of 32 miles per hour. Temp. 65		2. Blast at the rate of 47 miles per hour. Temp. 65		3. Blast at the rate of 57 miles per hour. Temp. 65		4. Blast at the rate of $84\frac{1}{2}$ miles per hour. Temp. 65°	
	min.	sec.	min.	sec.	min.	sec.	min.	sec	min.	sec.
From 160 to 150	3	33	2	..	1	30	..	41	..	25
From 130 to 120	8	30	1	10	2	4	1	6	1	7
From 100 to 90°	22	5	6	30	3	41	3	18	2	3

A higher velocity than $84\frac{1}{2}$ miles per hour was found prejudicial, as a portion of the wort was driven over the side of the vessel.

The relative loss by evaporation was

By natural cooling .... 1·40
By blast, at 32 miles per hour .... 1·45
Ditto at 57 miles .... 1·47

Hence it would appear, that the evaporation effected was about the same in all the experiments; and the rate of refrigeration nearly in the direct ratio of the velocity of blast.

These results induced the author to try other applications of the blast, by causing the wort to flow down over a series of slightly inclined planes, being exposed at the same time to a powerful ascending current of air from a fan blower. The introduction of air directly into the wort was, however, found to raise a froth or "fob," which would affect the soundness of the beer. Several other methods were tried, and at length the machine now described was constructed.

The wort is pumped up at a slow and regulated speed into a recipient at the top of the machine, divides into a series of thin films or streams, and trickles down the inside of a number of thin metallic tubes, set vertically, with their upper extremities quite level. Up these tubes is forced a current of air at any required velocity, which, meeting the descending wort, cools it inside, whilst a constant change of cold water takes place around the exterior of the tubes. The wort, on leaving the vertical tubes, is received into a second refrigerator, containing a number of horizontal pipes through which cold water flows. By this process the wort is cooled without producing any prejudicial effect upon its quality, and with a rapidity (as shown by the table) which would be extremely advantageous under certain circumstances.

This communication was accompanied by two drawings of the Refrigerator, and illustrated by a working model with which the experiments had been made.

"*An Account of the Repairs and Alterations made in the Structure of the Menai Bridge, in consequence of the damage it received during the gale of January 7, 1839.*" By T. J. Maude, Grad. Inst. C.E.

The roadway of the Menai Bridge having been seriously injured by the storm of January 7, 1839, it was deemed expedient to renew entirely the suspended platform: and at the same time to carry into effect certain alterations in the construction, suggested by constant observation of the working of the Bridge during thirteen years, as well as its condition after the storm.

In the original structure, each long roadway bar was fixed at three points to the vertical suspending rods. Motion being chiefly communicated to the roadway by the vibration of the windward chain, one end of the long bar suspended from it was lifted up, whilst the other two points of suspension remained nearly stationary. The bar thus became a lever with its fulcrum at the middle point of attachment, and at that weakest part it invariably broke. In order to remedy this defect, an augmented depth of half an inch has been given to the new roadway bars, with an additional enlargement round the eyes for attachment to the suspension rods, and each bar is hung from two points only, permitting it to play when the Bridge is subjected to motion.

The same vibratory action occasioned frequent fracture of the suspending rods close to the surface of the platform; to such an extent, that during the storm a great portion of the platform was entirely torn from its fastenings on one side, and hung down flapping in the gale supported merely by one line of rods. To remedy this, a joint has been introduced in each rod just above the surface of the platform, so as to allow the suspension rods free action, and permit a motion in either of the carriage-ways or the footpath independently of each other. The dimensions of the short suspension rods have been increased to one inch and a quarter square, whilst the remainder of the rods are only one inch square. The effects of the lateral and undulating motions are provided against by the direction of the working of the joints, one of them being in the line of the roadway bar, and the other at right angles to it.

Additional rigidity has been given to the platform by applying a course of three-inch planking laid transversely throughout its entire length, and bolted through each plank at intervals of two feet six inches apart, the oak beams originally placed beneath the platform having been entirely removed.

For the purpose of checking longitudinal undulation, two lines of beams, formed of two pieces of Baltic fir, each 40 feet long, 13 inches deep, and $4\frac{1}{2}$ inches thick, are framed to the trussed bearers, and bolted up beneath each carriage-way the entire length of the platform: at the same time an increased depth has been given to the wheel guides, which are also bolted through to to the planking. The total depth given by these strengthening beams and guides, is three feet four inches, while in the original structure it was one foot four inches.

The weight of the additional timber and iron-work introduced into the bridge, is about 130 tons. The whole of the timber has been Kyanized, and each coat of planking covered with Archangel tar; the felt has been discarded, as it does not appear to have answered its intended objects in the original structure.

In these alterations (which were designed by Mr. Provis, M. Inst. C.E.; one main object, which was never lost sight of, was to preserve that simplicity of construction which is so striking a feature in the original design; and should any future derangements occur, any part can be repaired or replaced without disturbing the rest of the structure.

This communication was illustrated by a drawing of the original platform, and of the alterations described in the Paper.

February 2.—The President in the Chair.

"*On a Method of setting out involute Teeth of Wheels, so that any two wheels of the same or of different diameters will work truly together, whether the teeth bottom or only just touch each other.*" By Edward Cowper.

The rule is briefly this:—

Point off the teeth on the pitch circle in the usual manner; then take the smallest wheel of the set, and having decided upon the depth of the proposed tooth, describe a circle (called the Evolute) touching the bottom of the tooth.

On all the other wheels describe evolute circles, bearing the same proportion to *their* respective pitch circles, which the evolute circle of the smallest wheel bears to *its* pitch circle—thus, if in the smallest wheel the evolute circle is $\frac{1}{12}$th less than the pitch circle, let all the other evolutes be $\frac{1}{12}$th less than *their* pitch circles. From these evolute circles as bases, describe the involute curves of the teeth, making the curves pass through the points set out for the teeth, upon the pitch line.

"*An Account of some Experiments to determine the force necessary to punch holes through plates of wrought iron and copper.*" By Joseph Colthurst.

These experiments were performed with a cast-iron lever, 11 feet long, multiplying the strain ten times, with a screw adjustment at the head, and a counterpoise.

The sheets of iron and copper which were experimented upon were placed between two perforated steel plates, and the punch, the nipple of which was perfectly flat on the face, being inserted into a hole in the upper plate, was driven through by the pressure of the lever.

The average results of the several experiments (which are given in a detailed tabular form) show that

The power required to force a punch	Inch diam. 0·50	Through an iron plate	Inch thick. 0·08	is 6025 ℔.
Ditto	0·50	Ditto	0·17	is 11,950 ℔.
Ditto	0·50	Ditto	0·24	is 17,100 ℔.
Ditto	0·50	Through a copper plate	0·08	is 3983 ℔.
Ditto	0·50	Ditto	0·17	is 7883 ℔.

Hence it is evident, that the force necessary to punch holes of different diameters through metal of various thicknesses, is directly as the diameter of the holes and the thickness of the metal.

A simple rule for determining the force required for punching, may be thus deduced.

Taking one inch diameter, and one inch in thickness, as the units of calculation, it is shown that 150,000 is the constant number for wrought-iron plates, and 96,000 for copper plates.

Multiply the constant number by the given diameter in inches, and by the thickness in inches; the product is the pressure in pounds, which will be required to punch a hole of a given diameter, through a plate of a given thickness.

It was observed, that duration of pressure lessened considerably the ultimate force necessary to punch through metal, and that the use of oil on the punch reduced the pressure about eight per cent.

A drawing of the experimental lever and apparatus accompanied the communication.

"*Geological Sections of Railway Cuttings.*" By Mr. Sopwith.

Mr. Sopwith called the attention of the meeting to the valuable Geological Sections presented by the railway cuttings, and other engineering works now in progress; this was particularly the case on the North Midland Railway, where the crops of the various seams of coal, with the interposing strata, were displayed in the clearest manner, developing the geological structure of the country which the railway traverses. Numerous similar instances induced the British Association to devote a sum of 200*l.* (which it was believed would be increased from other sources), for obtaining authentic records of such sections, before the action of the atmosphere or the progress of vegetation should have obliterated the instructive pages of geology, which the engineer had opened to view.

The Committee of the British Association, especially charged with this subject, were desirous of bringing it before the Institution of Civil Engineers, for the double purpose of receiving from its Members those suggestions which they are so competent to give, and of obtaining from them that powerful aid and co-operation which the practical nature of their engagements so essentially enabled them to afford; it was accordingly suggested, that the Council should receive from Graduates, descriptive papers and measured delineations of sections, as their communications previously to their Election. Much assistance might thus be rendered, and the contributions, after having been read at the Institution, might be added to the general series preserved in the Museum of Economic Geology, which under its present able direction is becoming daily more interesting both to the engineer and the geologist.

Mr. Sopwith exhibited a specimen of a blank chart, prepared by Mr. Phillips, of York, for the committee. It consisted of a sheet engraved in squares, on a scale of 40 feet to an inch, containing a space equivalent to 800 feet in length, and 600 feet in height, upon which it was proposed to delineate the sections in their true vertical and horizontal proportions; the base line representing either the level of the sea at half tide, or the datum line of the railway, as might be most convenient. There would remain in every case a large portion of the sheet unoccupied by the section, and upon this it was proposed to exhibit, on a magnified scale, the details of the section; the fossils and other organic remains might also be shown, as the divisions of the squares would enable the sketches to be made of any dimensions in correct proportions. An example of these charts had been prepared by Mr. Phillips, giving a section of a deep cutting on a railway, the enlarged portion exhibiting the details of the strata at two particularly interesting points, as also of the specimens of sigillaria, stigmaria, &c. in that formation.*

Geological Models.—Mr. Sopwith also laid before the meeting a set of models, which were intended as hand specimens for the purpose of familiarly explaining faults, slips, or dislocations of the strata, and other geological phenomena, which could not be clearly demonstrated without such assistance. One of these models represented the horizontal deposition of stratified rocks, and the subsequent removal or degradation of such rocks, forming valleys of denudation. Another, by the displacement of the lower rocks, exhibited the formation of a slip dyke, or fault, which was the "lode or vein" of the mineral miner, and the "fault" or "trouble" of the collier, as these interruptions of the continuity of the bed of coal were generally termed. Another model showed a succession of slip dykes disturbing the stratification, so as to present the appearance of a great abundance of coal at the surface by the "cropping out" or "bassetting" of a number of seams or beds of coal, whereas in reality there was only a repetition of the same beds. By examining the base of the model, and also by opening it on an oblique plane nearly parallel with, and at a short distance below, the surface, it would be found that there was no coal at all. A fourth model exhibited the conditions under which some of the largest collieries in the kingdom are worked, namely, that the seams of coal do not appear on the surface, but on opening the model a vertical section is exhibited, and the several beds are shown, disturbed as in the former case by faults or dislocations, but which have not the effect of bringing the coal to the surface.

It has always been difficult to demonstrate without the aid of models the apparent form of strata, as effected by the contour of the country; sometimes the rocks form a V, pointing up the valley, and sometimes in the opposite direction. General observers and even practical miners were apt to conclude, that this different direction of the point of the V, indicated a different direction of the strata, but the models showed that in both cases the direction of the strata was the same; that in both cases the rocks were inclined in the same direction as the valley, the only difference being that in one case the rocks form a greater, and in the other a less, angle with the horizon than the bottom of the valley. The other models exhibited the "up-cast" and "down-cast" which occur in coal mining, and intersections of veins of different ages, &c. Most of the specimens shown presented details of the carboniferous formation, but models of this description were of course applicable to every formation and to every kind of geological structure. Mr. Sopwith brought forward this subject in hopes that eventually a close union and active co-operation might be established between the leading scientific institutions of this country, and more especially that the Geological Society and the Institution of Civil Engineers would unite in promoting the progress and improvement of geology and engineering.

February 9.—The President in the Chair.

The following were balloted for and elected: Sir Charles Baird, as a Member; Samuel Beazley, William Gossage, John Hughes, John Howkins, and Charles Schafaeutl, M.D., as Associates.

"*Upon the Application and Use of Auxiliary Steam Power, for the purpose of shortening the time occupied by Sailing Ships upon distant voyages.*" By Samuel Seaward, M. Inst. C.E.

But few years have elapsed since the possibility of propelling vessels by the power of steam was treated as a chimera; and although the practicability of its application for short voyages has been successfully demonstrated by the numerous vessels plying between this country and the Continent, it is but of very recent date that its employment for long sea voyages has been adopted. The weight of the powerful machinery and the fuel, and the consequent loss of space for cargo, together with many other circumstances attendant on the present construction of steam vessels, induced the author (who received the education of a seaman, and has since had extensive practice as an engineer) to believe that a more efficient mode of employing steam power for long sea voyages might be adopted.

Notwithstanding the great improvements which have taken place in the construction of steam vessels, and their machinery, it would appear that the duration of the voyage ought not to exceed twenty days, after which time a fresh supply of fuel becomes necessary; hence, steam has rarely been adopted for very long voyages. The reason of this limit to the duration of the voyage of a steam vessel, as at present equipped, is that an increase of power does not produce a corresponding increase of speed, while the weight of the machinery increases in proportion to the power employed, and in some cases exceeds it; for instance, small engines, with the water in the boilers, generally weigh about one ton per horse power, while in some large engines the ratio is nearly twenty-five cwt. per horse power.

A quadruple increase of power will not produce double the original velocity in a steam ship, although, in theory, such is assumed to be the case; for as the weight is more than doubled, the immersed sectional area becomes greater, and a still further increase of power is necessary. It has been shown by experience, that if a vessel with a given power is propelled through the water

* Specimens of the prepared sections and blank charts may be obtained from Mr. Delabeche or Mr. Jordan, at the Museum of Economic Geology, Craig's Court, Charing Cross, or from the Secretary of the Institution of Civil Engineers.

at the rate of eight miles per hour, her speed cannot be doubled, even though the power be multiplied twelve times, and the entire hold of the vessel occupied as an engine room.

The weight of fuel is also in direct proportion to the size of the engines; so that taking, for example, two vessels of two hundred and of four hundred horses power respectively—that of the higher power will have to carry nearly double the weight both of fuel and of engines, and it is still questionable whether the increased force will propel the one ship more than 1½ mile per hour faster than the other.

The space occupied by the engines and fuel in the most valuable part of the ship, is also an important consideration: neither the "President" nor "British Queen" steamer, although of two thousand tons measurement, is capable of carrying more than five hundred tons of cargo when the fuel is on board.

The author then examines the question of employing too much power in a steam vessel, and refers to the "Liverpool," as an instance that such may be the fact. It appears that with the original dimensions of thirty feet ten inches beam, and engine power of four hundred and fifty horses, being a proportion of power to tonnage of about 1 to 2¼, the vessel was immersed four feet beyond the calculated water line, and a decided failure was the natural consequence; but when the breadth of beam was increased to thirty-seven feet, augmenting the capacity four hundred tons, and giving the proportion of one horse power to 3¾ tons burthen, the performance of the engine and the speed of the vessel were both materially improved.

The "Gem," Gravesend steamer, one hundred and forty-five feet long, by nineteen feet beam, had two engines of fifty horses power each; the speed was insufficient, being only twelve and a half miles through the water; but when the same engines were placed in the "Ruby," which was one hundred and fifty feet long, and nineteen feet nine inches beam, the velocity of the latter vessel was thirteen and a half miles per hour. A pair of engines, of forty-five horses power each, were then placed in the "Gem," without altering the vessel, and in consequence of the diminished weight and draught of water, her speed then nearly equalled that of the "Ruby."

The author does not condemn the application of considerable power for vessels, provided it can be employed without materially increasing the weight and the area of the immersed midship section. It appears that the length of a steam voyage, to be profitable, is at present limited to twenty days for the largest class of steamers; that we have about thirty others which can approach twelve days, while the majority cannot employ steam beyond eight days successively, without a fresh supply of fuel. It is evident, therefore, that more efficient means must be adopted for the general wants of commerce in our extended intercourse with the East and West Indies, the Pacific, Mexico, Brazil, Australia, and all the distant colonies, which now demand rapid communication with England.

The author refers to a pamphlet, published by him in 1827, entitled, "Observations on the possibility of successfully employing Steam Power in navigating Ships between this country and the East Indies by the Cape of Good Hope." He therein proposed that large square-rigged ships, of fifteen hundred to eighteen hundred tons measurement, should be fully equipped and constructed, so as to sail ten or eleven miles per hour with a fair wind; that they should carry engines of small power, to assist the sails in light winds, propel them at a moderate speed during calms, work into and out of harbour, &c., and thus shorten those portions of the voyage wherein so much time was usually lost.

To all well-built good-sailing vessels, of four hundred tons and upwards, "auxiliary steam" is applicable. A steam engine of the necessary power can without inconvenience be placed in such vessels, either on or between decks, so as propel a ship at the rate of four to five nautical miles per hour in a calm, and for this speed a proportion of one horse power to twenty-five tons is amply sufficient. The practicability of applying this system to East Indiamen and other similar vessels is then examined at length, and it is shown that the ordinary speed of these ships under sail is, before the wind, eleven to twelve miles per hour, and in a gale thirteen to fourteen miles per hour, which is greater by two or three miles per hour than that of any ordinary steam vessel when under sail, on account of the latter being impeded by the wheels trailing in the water, and the slightness of their masts, spars, and rigging. The auxiliary steam power might, therefore, be efficiently applied, either by using it alone, or in conjunction with the sails, so as to keep up a uniform speed, by which a great saving of time could be effected in a long voyage.

The conditions of sailing and steaming voyages to India, with the influence of the trade-winds, are then examined, and the author proceeds to detail the experiments made by him, on board the "Vernon" Indiaman, which was the first sailing vessel that actually made a voyage out and home with "auxiliary steam."

The "Vernon," built in 1839, by the owner, Mr. Green, was one thousand tons burthen; the sailing speed was about twelve to thirteen miles per hour in a fresh gale, and being from her frigate build well calculated for the experiment, it was determined to equip her with a condensing engine of thirty horses power, placed midships on the main deck, between the fore and main hatchways; the space occupied being twenty-four feet long by ten wide. The weight of the machinery was twenty-five tons, and it was so arranged that the motion was communicated direct from the piston cross-head by two side rods to the crank on the paddle shaft, placed immediately behind the lower end of the steam cylinder, which was horizontal. The wheels were fourteen feet diameter, projecting five feet, and were so constructed that the float boards could be raised to suit the draught of water of the ship; or they could be taken entirely away, if necessary, leaving the shafts projecting only eighteen inches beyond the sides. Under ordinary circumstances they were disconnected from the engine by a simple contrivance, consisting of a moveable head, attached to the crank on the paddle shaft, by turning which, one quarter of a circle, the crank pin was liberated, and the wheels turned freely round. The "Vernon," thus equipped, having on board nine hundred tons of cargo, and sixty tons of coal, drew seventeen feet of water. In the first trial the speed of the vessel, under steam alone, was five and three-quarters nautical miles per hour, demonstrating how small a power is necessary for a moderate speed. She then started for Calcutta, and though the piston rod broke three times during the voyage, owing to a defect in one of the paddle shaft bearings, the passage was satisfactory. The details are given minutely, as are also those of those homeward voyage, which was performed from Calcutta to London in eighty-eight days, to which must be added seven days for necessary delay at the Cape, making a total of ninety-five days, which is the shortest passage on record. Great credit is given to Captain Denny for the judgment with which he used the auxiliary steam power, and the course taken by him, by which he was enabled to overcome the difficulties incidental to a first trial of so important a system. The success of the "Vernon," induced the immediate application of engine power to the "Earl Hardwicke" Indiaman, and both these vessels are now on their voyage out to Calcutta.

This communication was accompanied by drawings of the "Vernon" and the "Earl Hardwicke," and by a chart, on which was laid down the proposed daily course of a steam ship, on a voyage to and from Calcutta, showing where sails only are necessary, then where steam alone, and also when the joint agency of steam and wind would be required. Also, the daily progress of the "Marquis of Huntly" Indiaman, of fourteen hundred tons burthen, on a voyage to India and China, and home, from the author's own observation, in the year 1816.

For the purpose of demonstrating the ratio of power to velocity, a Table was also given showing the velocities of ships of different tonnage, having steam power of various ratios, deduced from upwards of one hundred experiments on large steam vessels. The mode of disengaging the cranks was illustrated by models showing the gradation, from the complication of the first idea, to the beautiful simplicity of the present plan, which is now employed on board of the Government war steamers.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

April 19.

The Institute met for the first time after the Easter recess. Jos. Kay Esq., V. P., in the Chair.

Beriah Botfield, Esq., M. P., was unanimously elected an Honorary Fellow.

The Secretary announced the subjects for the prizes for the ensuing Session, viz. a restoration of Crosby Place, Bishopsgate Street, with the addition to the medal of ten guineas liberally offered by Miss Hacket, to whom the public are so greatly indebted for the preservation of what remains of that fine specimen of the Palatial architecture of the 15th century; an essay on the properties of light, shade and reflection in architecture, and another on the effects which may result to architectural design, from the general use of cast iron in construction.

A paper was read by Mr. Poynter, Fellow, on the state of Windsor Castle, previously to the erection of the existing *domus regis* by Edward III, in the 14th century. It is unnecessary to enter into any analysis of this paper, as the materials were drawn from a prefatory essay to Sir Jeffry Wyatville's illustrations of Windsor Castle, which will immediately be in the hands of the public: but that portion of it which was laid before the Institute, was made illustrative of a ground plan, in which the condition of the Castle, as it was left after the extensive alterations of Henry III. was laid down upon the authority of original documents, the greater part of which have now been brought to light for the first time.

A communication was read from John White, Esq., in pursuance of the subject brought before the Institute at a former meeting, the remains of ecclesiastical architecture in the pointed style, at Wisby, in Gothland. Mr. White's supplementary paper went to support, by the authority of Torfœus, and other historians, his theory on the date of those buildings, by adducing evidence on the advanced state of the arts in Scandinavia, as early as the tenth century.

The meeting adjourned to the refreshment of tea and coffee in the Library.

On Monday evening of the 26th ult., the President Earl de Grey, opened his house for the reception of the Members of the Society. The Council had the honour of dining with his Lordship, and the conversazione which followed was attended by a numerous party of noblemen and gentlemen eminent in art, science and literature. The Marquis of Lansdowne, Lord Prudhoe, Mr. Baron Parke, Mr. Rogers, Sir Edward Cust, Sir Henry Halford, Sir Henry Ellis, Sir Richard Westmacott, Sir Francis Chantrey, Sir Frederick Madden, Sir Gardner Wilkinson, Sir John Rennie, Sir Isambard Brunel, Professor Willis, the President of the Institute of Civil Engineers, Mr. Allan Cunningham, Mr. Copley Fielding, Mr. Ross, Mr. Harding, Mr. Haghe, and Mr. Joseph Nash were among the guests. A small party of ladies were also present, including the Duchess of Northumberland, the Marchioness of Lansdowne, &c. The tables were covered with works of art, among which Mr. Nash's splendid drawings of old English mansions were conspicuous.

RANDOM NOTES ON STEAM NAVIGATION.

"A very cursory survey of the various nations into which in the designs of Providence this earth of ours is portioned, cannot fail to excite our wonder and admiration of His master-workings for this our favoured habitation. While the British Isles appear a mere speck, as it were, upon the surface of the ocean, and are gifted with none of what are usually described as the more precious productions of nature, and while Golconda with her diamonds, and Peru with her gold, have scarce yet emerged from the obscurity of barbarism, we are naturally led to the enquiry as to *how* our little nation has surmounted the difficulties that might have daunted her energies and baffled her progress, and marched triumphantly forward until the clarion of her renown and the majesty of her sceptre have awed the very outskirts of the world. With a soil requiring laborious tillage for its culture, but with that abundantly productive of the necessaries and even the luxuries of life, with mines rich in the baser ores, yet prompting the researches of the chemist, the metallurgist, and the manufacturer, to administer to their profitable appropriation, and with such vast resources in her coal fields as have abundantly sufficed for the efficient development of her other subterraneous resources, her native energies have been kindled through difficulties. Scorning the limits of indigenous productions, the world has been ransacked for the gratification of her insatiable enterprizers. Nation after nation has bowed to her triumphant sway, while at home she has devoted herself to such subtle ingenuities as have, at length, evented in her careering through space with the velocity of the eagle, or trampling over the ocean as the mighty leviathan."*

A review of the progress and extension of the art of steam navigation would be the highest testimonial of its intrinsic and consummate importance Twenty years have scarce elapsed since, amid incredulity and ridicule, Fulton committed his little steam pinnace to the bosom of the Hudson; and long posterior to that event, the idea of traversing the ocean by the agency of steam was regarded as visionary and unattainable. Yet, within a few years, have we witnessed not merely the realization of this idea, but the extension of steam navigation to every part of the habitable globe. Every sea has become the scene of its triumphs—every land the recipient of its attendant beneficence. The frigid barriers of the pole have been constrained to attest its power—the dreary wastes of the Atlantic have been compelled to acknowledge its sovereignty. Art has usurped the dominion of Nature, and subjected even the elements to its sway. It would be difficult to form any adequate estimate of the effects on the moral and physical condition of mankind which may be expected to arise from the operation of this wonder-working agent. Every line of rapid and commodious communication between nation and nation is a channel through which knowledge, civilization and benignity will flow; and these main streams, by their subdivision into numerous minute ramifications, will transmit to the most obscure regions a portion of their invigorating influence, like the generous river of Egypt, which distributes its waters through innumerable channels to revive and fertilize the thirsty soil. Amid the general enlightenment resulting from these influences, national antipathies will be extinguished, and superstition and intolerance will cease to exist, and the irresistible progress of knowledge, the stately march of liberty, the happy approach of that period when the gorgeous East shall cease to shower on her kings *barbaric* pearls and gold, may be referrible to the achievements of modern ingenuity in the completion of this its most stupendous monument.

It would be irrelevant to our present purpose to pursue these considerations. We therefore proceed at once to announce our intention to embody, in a series of articles, the essential part of whatever information respecting steam navigation we ourselves possess, to explain those scientific principles which are essential to an intimate knowledge of the marine steam engine, and to communicate such practical details and precepts as extensive opportunity of investigation and considerable experience have enabled us to collect.

It is a circumstance which has frequently excited surprise and regret, that notwithstanding the important position which steam navigation has now universally assumed, there is yet no practically useful treatise devoted to its consideration. Dr. Lardner's elegant treatise on the steam engine is only adapted to the unprofessional reader, and the able treatise of Mr. Farey does not, in the only volume that has yet been published, embrace the subject of steam navigation. The recent edition of Tredgold contains much valuable information on the subject of steam navigation in the form of an appendix; but having been communicated by different individuals, it wants unity and sometimes consistency. Useful facts and valuable deductions are mixed up with inexact information and irrelevant narrative. To make a judicious selection from such a heterogeneous compilation to appropriate what is important and authentic, and reject what is valueless or inaccurate, pre-supposes the possession of that knowledge which it is the object of the student to obtain.

The production of a useful practical treatise upon the subject of steam machinery requires the agency of an able practical engineer, and there are few skilful engineers who cannot more beneficially occupy their time than in subjecting themselves to the unrequited labours of authorship. Among the makers of steam engines there are some who possess the requisite knowledge for the production of an able and valuable treatise upon the machinery of steam vessels, but independently of the importance of their time, there exists the strongest disinclination to reveal the mysteries of their profession, or to furnish any information relative to the qualities or nature of particular modes of construction. Each maker considers that he possesses some superior contrivance, arrangement or adjustment, the secret of which he desires to retain for his individual benefit, and the nature of which he endeavours to keep unknown even to his own workmen. Some regard the setting of the valves as their forte—others the proportion of their boilers, and others the peculiar mode of finishing or fastening certain parts of the machinery. The acquisition of a competent knowledge of the business of an engineer is in consequence an achievement of the utmost difficulty—information has often to be clandestinely obtained, and of the few who by dint of assiduity and good fortune, succeed in forcing their way into the sacred penetralia, appeared desirous to avenge himself for the labour, by excluding as many as possible of his neighbours.

We cannot but regard the secrecy which has been attempted to be preserved upon these subjects, as a reproach to the present liberal and enlightened age. It is a remnant of the ancient policy which nearly a century ago governed Boulton and Watt's establishment, and which, though at that time circumstances might perhaps have rendered it prudent and advisable, is at the present day inexcuseable and ridiculous. What secrets are they which the makers of steam engines have it in their power to conceal? Their works go abroad to the world, are cast in the course of events into the hands of other engineers, by whom they are dissected and criticised, when every peculiarity they possess is at once recognized and made public. Is it then expedient to reveal the existence of an illiberal spirit where it is impracticable to exercise an illiberal policy? Is it wise to proclaim to the world that we would desire to repress the interchanges of knowledge, and restore the ancient dominion of ignorance and empiricism? Have we the hardihood or the indiscretion to confess that with us impotency is the only limitation to restriction? "The whole tendency of empirical art is to bury itself in technicalities, and to place its pride in particular short cuts and mysteries known only to adepts; to surprise and astonish by results, but to conceal processes. The character of science is the direct contrary. It delights to lay itself open to inquiry, and is not satisfied with its conclusion till it can make the road to them broad and beaten: and in its applications it preserves the same character; its whole aim being to strip away all technical mystery, to illuminate every dark recess, and to gain free access to all processes, with a view to improve them upon rational principles.*" But it would be vain to expect that engineers will become converts to these enlightened views so long as their supposed interests lie in another direction—so long as they imagine the exercise of a craft to be more profitable than the practice of a profession, and that it is practicable to conceal, and yet employ the secrets of which they imagine themselves to be possessed. The constitution of human nature is opposed to such a consummation; and it would be too much to expect that our mechanical engineers should be an exception to the general disinclination to sacrifice accredited private interest to the cause of philanthrophy or of public duty.

The extinction of this spirit would be productive not merely of benefit to the community, but would enhance the reputation and promote the interests of our leading engineers themselves—we shall accomplish an object which we conceive ought to be generally acceptable, if we contribute to the obliteration of this, the only blot with which their fair fame is sullied.

It will be manifest from the title we have chosen, that in the observations we have to offer, we do not bind ourselves to an adherence to systematic arrangement—nevertheless we shall endeavour to thread all our memorandums upon the same string, and that too with some approximation to order. For the sake of continuity it will often be necessary to repeat what may have been said before: indeed we advance no pretensions to originality, although we are sensible it may be

* Thoughts on Steam Locomotion. Weale, 1840.

* Sir J. Herschell.

found that much of the information we may furnish is not to be found in any other publication.

The heads under which our observations will be given, are—

1st. Heat.
2nd. Steam.
3rd. Investigation of the reciprocal proportions of marine engines.
4th. Investigation of the requisite strength of the parts of ditto.
5th. Boilers.
6th. Practical details.

Critical and illustrative annotations by Mr. Farey, Dr. Lardner and others, will be appended, which, for the sake of distinction, will be marked with their respective initials.

Beth.

WESTMINSTER BRIDGE.

In the preceding volumes of our Journal we gave several notices of the repairs and improvements in progress at Westminster Bridge, and have now great pleasure in fulfilling our promise of continuing them.

The second coffer dam has been closed within the last five months, and a more successful result from work of this description we have never witnessed; indeed it appears to be one of the greatest triumphs of hydraulic engineering, to find a dam, (erected in a tidal river with a rise and fall of 18 feet of water, and exposed to every trial that one of the severest winters on record could subject it to,) so completely resist the efforts of its most insidious adversary, that after the wear and tear of five months, there is scarcely sufficient water from leakage to supply the ordinary demand of the works, and this too, on ground that was declared unsuited for the purpose, by the engineer who constructed the bridge, and by all who succeeded him up to the time when the present works were commenced, if we may judge from the way in which they carried on the repairs, and from the schemes for restoring it as exhibited in their reports.

The present dam encloses the 16 feet and 15 feet piers. Of the former we have only to observe, that the foundations were found similar to those in the first dam, the caisson resting on a bed of gravel, underneath which was the blue clay; they have since been secured in the manner already described in a former notice (vol. ii. p. 203), and the masons are proceeding with the new facing, of Bramley-fall stone, above the lowest low water mark, and also with the extension of the pier on the upper side, whereby the roadway may at any future time be widened 12 feet, without again having recourse to the expensive preparation of coffre dams.

The 15 feet pier is the one memorable in the history of the bridge, as having, by its sinking, delayed the opening to the public for three years, and given an apology to the party opposed to Labelye, (the engineer), to assail him with every slander that malice could invent, and by tampering with the commisioners, to nearly prevent the completion of the bridge according to his original design. How severely this treatment affected Labelye, we may see from a work published by him afterwards, in which he repels their attacks with great spirit, and with a bitterness that must have arisen from feeling himself deeply injured. We will here give a few extracts from this work, detailing the extent of damage done to the bridge by the accident, and the means he adopted to remedy it.

"On the 14th November 1746, the bridge and the roads and streets on both sides were completely finished, and the whole was performed in seven years nine months and sixteen days. The commissioners intended soon after to have opened the bridge for the service of the public, but were prevented by an accident entirely unforeseen, and not easily accounted for. In the months of May and June, 1747, the western fifteen foot pier was perceived to settle, very gently at first, but so much faster towards the end of July, that it was thought absolutely necessary to take off the balustrades, &c., by the continuation of the settling, the adjoining arches lost their semicircular figure, and considerable openings in the joints showed them in danger, some of their stones both in their fronts and soffits were split and broken, and one of them actually fell out of the least arch into the river."

The first steps taken were to carry up the two external piers of the two arches that were damaged quite solid, in rubble stone and mortar, to the level of the top of the arches, and to load them sufficiently, in order to preserve the other arches and piers of the bridge; centers were then put up to carry the two arches, and they commenced loading the damaged pier. The account of the last proceeding Labelye thus describes: "the whole weight of load placed on the said pier was so far magnified by writers of daily news and monthly magazines, as to be called 12,000 tons, while it never did exceed 700 tons, which was about a third of what I intended to load it with." What prevented this, was the influence of the party opposed to him, who persuaded the commissioners that further loading would be dangerous, and prevailed on them to give him orders to unload the pier, and take down the damaged arches." "This order," says he, "was the first and only one I ever received from the commissioners contrary to my judgment or opinion, and which I obeyed, *but I own not without some concern*."

We may here remark that the execution of this order, (as will be seen in the latter part of our notice,) has allowed the pier to remain in an unstable condition ever since, and had it not been for the successful repair lately effected, must finally have occasioned the destruction of a portion of the bridge.

His next proceeding was to inclose the foundation with 12 in. piles, and to rebuild the arches: "the dove-tailed piles were driven all round, close to the bed of timber on which the pier is built, and so deep as to reach about 15 feet under it all round, and afterwards were all sawn off low enough below low water mark, as never to be any obstruction to the navigation of any boat or vessel. Then the two damaged arches were rebuilt the very same in appearance, but with much less material in the inside."

After the preceding extracts, an account of the state in which the pier was found when the water was excluded from the dam, and of the works executed since then to secure its stability, cannot fail to be interesting to our readers.

On the removal of the ground about the pier, the joints of the dove-tailed piling, described above, were found any thing but close, and to make the matter worse, several of the piles had broken in the driving. As no dependence could be placed in this work, new sheet piling, of the same description as that used for the 16 feet pier, was driven all round, enclosing the foundation, thus at once preventing the escape of the finest particles of sand from under the pier. The old piles were afterwards sawn off at a low level, in preference to drawing them, as it was thought their removal might disturb the ground.

During the progress of driving the piles, considerable movement took place in the adjoining arches, showing evident symptoms of further sinking in the pier, and to prevent any injurious effect upon the masonry, strong shoring of whole timbers was fixed from the coffre dam to the soffit of the 64 feet arch, a precaution that has been attended with considerable advantage, as the arch stones have remained nearly uninjured, although several of the mortar joints were broken.

On the removal of the ground within the sheet piling, the projecting part of the timber bottom of the caisson was found to be broken and separated from that part underneath the pier, this had arisen from the space intended for the caisson not having been dredged sufficiently large to receive it, so that it was resting on the slope of the excavation, the centre part being hollow, until the weight of the masonry broke away the sides and allowed the pier to settle on the loose sand and gravel which had run in; the level of the blue clay being nearer the surface at this pier than the adjoining one, the excavation was principally in that material, and its intense stiffness will account for the dislocation that took place in the timber work.

The critical position of this part of the work required much caution, and in applying a remedy to so uncommon a case, we are glad to bear testimony to the most perfect success of the plan adopted; we have no doubt that this pier is *now* as trustworthy as any of the others that have been taken in hand.

The whole of the disturbed foundation timbers were removed, as also all the loose and muddy ground to the solid clay—the depth in some parts being as much as two feet,—under the foundations a body of concrete was filled in, level with the underside of the caisson, and to increase the bearing of the pier, timbers were laid parallel to the sides of the caisson, crossed by others placed 18 inches apart, and inserted to the length of 2 feet 6 inches under the masonry,—to insure their perfect bearing each timber was cut wedge form, and driven tight into the space it was intended to occupy. This operation was continued all round the pier, thus increasing its bearing surface about three feet on each side.

From that level a mass of brickwork was built, backed with concrete to receive the stone work of the pier, which in this case is to form a projecting footing of masonry, and the space within the sheet piling is to be finished with a capping similar to the other piers.

The masons are now employed upon this part of the work, and in extending the pier for widening the roadway, and if we may judge from the number of men employed, and vast store of materials provided, no very long time will elapse before the use of that magnificent temporary work, the dam, may be dispensed with.

We are happy in having had this opportunity of removing the uncertainty and error that has hitherto prevailed about the settling of this pier,—it has always been attributed to the ballast-men lifting gravel too near the foundations, and the late Mr. Telford and others in their plans for securing the piers, had only one object in view, that of preventing any further scour from the river—in the present instance we find that there was another and more serious danger to guard against, and that without the assistance of the coffre dam, the sunken pier could *never* have been made secure—on the contrary, that any attempt by driving piles or otherwise, if access could not have been had to the interior might have proved fatal to the adjoining arches.

We hope soon to have it in our power to announce, that the commissioners see that the time has arrived when they may confer a great and lasting benefit on the public, by widening the roadway of the bridge, "a consummation devoutly to be wished," by every one who has occasion to pass over it in its present narrow and crowded state.

ON THE POWER OF THE SCREW.

SIR—Permit me to offer you the following article which I hope you will deem worthy of publication in your Journal.

I am your most obedient servant,

J. R. CUSSEN.

Bruff,
March 30, 1840.

I have been often consulted as to the application of the screw as a mechanical power, and frequently found theory at variance with practice, this led me to an investigation of the rule generally used, for calculating its power, to practical trials of its power, and to an elucidation of a rule different from all those I know to be in use, which I trust will be found correct.

The Rev. Mr. Bridges in his work on Mechanics, p. 281, states, that P : W : : d : cirf. of cylinder, d being in his words the distance between two threads of the spiral, in p. 287, he says that p : W : : d : cirf. of cylinder, and P : p : : cirf. cylinder : cirf. of circle *ex æquo* P : W : : d : cirf. of circle ∴ $W = \frac{2\,p\,a\,P}{d}$, a = length of lever, but he makes $p = 3{\cdot}1415$, and also p = the power acting on the surface of the cylinder, thus making p in the same equation variable and invariable. In his application of the above formula he uses $p = 3{\cdot}1415$, but omits p = power acting on the surface of the cylinder, he adds in a note (*b*) that P : W : : d : cirf. of the circle. *Whatever be the thickness of the cylinder on which the screw is cut.* He then gives this rule. The power necessary to sustain the weight or produce the pressure will always bear to that weight or pressure, the ratio of the distance between any two spirals of the screw to the circumference of the circle which the power describes, that is $\left(W = \frac{2\,p\,a\,P}{d}\right)$ the weight to be raised or pressure produced is equal to twice the radius of the lever × 3·1415 × the power applied, and this product divided by the distance between the threads.

The first objection that struck me was why d should represent the distance between the spirals, and not the elevation of the inclined plane, or the elevation or depression obtained by each revolution of the cylinder, this is generally the distance between two threads + the thickness of the thread, or twice the distance between two threads; it is obvious that if the thread be ½ inch, and the distance between the threads ½ inch, that the elevation of the inclined plane, or the elevation or depression obtained at each revolution of the cylinder will be one inch.

The second objection was to the deduced conclusion that the diameter of the cylinder was of no importance, or that a screw of 2 inches diameter was as powerful as one of 12 inches or 100 inches. Suppose that no lever is used, and that the thread is the same in each, say ½ inch, and that the advantage obtained by the inclined plane be calculated we have for the 2 inch diameter screw 1 : 6·283 : : P : W, and for the 12 inch diameter 1 : 37·698 : : P : W, that is, the 12 inch diameter considering it merely as an inclined plane will sustain in equilibrio six times the weight with the same power that the 2 inch diameter screw will sustain.

That this power or advantage could be lost by the application of the same lever is absurd.

The third objection was to multiplying by the circumference of the circle formed by the extremity of the lever, instead of by the radius of the lever, as well may the circumference described by every lever be calculated, the error in calculating the power of the wheel and axle by the circumference would be apparent; in fact a screw is but a revolving inclined plane. Motion and power being communicated to it by a lever; moreover this inclined plane is properly speaking a fox-wedge, that is, two inclined planes of equal height acting on each other, for whatever space the threads of the screw pass over that of the nut, the threads of the nut pass over the same space on the threads of the screw, and both *i. e.* the threads of the nut and the threads of the screw sustain equal parts of the weight or pressure.

The power gained by the Rev. Mr. Bridge's formula by taking credit for the circumference of the lever, and dividing by but half the elevation of the inclined plane, is more than lost by omitting the advantage gained by the inclined plane in large screws, and the power of small diameter screws is overrated.

I am convinced that the true basis for calculating the power of the screw is P : W : : d : circumference of cylinder, d being the height of the inclined plane or the elevation or depression obtained by each revolution of the cylinder, then this advantage multiplied by the power applied, and the product divided by the height of the inclined plane, that is,

As the elevation obtained at each revolution, or as the height of the inclined plane,
: circumference of the cylinder,
: : the power applied
: the weight or pressure,

or $W = \frac{P \times \text{circumference of cylinder}}{d}$; the formula most generally wanting in use.

Suppose three screws, each of ½ inch thread, worked by a lever 90 inches long, the lever moved by a windlass of one ton power, the screws to be of 3, 6, and 9 inches diameter, we have the weight raised or pressure produced, by the

							tons.
3 inch diameter screw thus	1	:	9·4245	: :	90×1	:	848·205
by the 6 ditto	1	:	18·849	: :	90×1	:	1696·41
by the 9 ditto	1	:	28·2735	: :	90×1	:	2546·15

By the Rev. Mr. Bridge's formula we have for the three but one power, $W = \frac{2\,p\,a\,P}{d}$, *i. e.* $W = \frac{2 \times 3{\cdot}1415 \times 90 \times 1}{\frac{1}{2}} = 1130{\cdot}94$ tons.

It is to be remembered that one-third of the calculated power of the screw is lost by friction.

It is my opinion that the screw could be made to supersede the capstan in patent slips and dockyards, and that it could be used to the greatest advantage in submarine operations and excavations: its practical application to these objects will form the subject of another article.

COMPETITION.

SIR—A very suspicious looking advertisement having appeared in the Times of the 12th instant, offering a premium of 20*l.* for designs, estimates and specifications for a church to hold 800 or 1000 persons, to be built at Turnham Green, I applied according to the directions given in the advertisement, for information upon two or three points of some importance, viz. how much money it is proposed to expend—what means the advertisers would take to ascertain that the accepted design could be executed for the estimate which accompanied it—and whether the successful candidate would be employed in case he proved to be an architect of good reputation and experience. In answer to which queries I am informed,

"That the site is level and the soil gravel—
That the expenditure is not to exceed £3,500—
That one-third of the sittings are to be free—
That no vaults are required—
And that these are the only additional particulars the Secretary to the Committee can furnish."

Perhaps you can find room to publish this information for the benefit of the profession.

I am, Sir, your obedient servant,

B. T.

April 19, 1841.

Inclosed is my name and address.

Steam Navigation to the West Indies.—The first of the splendid line of steam packets intended to carry the mails betwixt this country and the West Indies, has been launched from the building-yard of Messrs. Duncan and Company, at Greenock. This vessel, which is 1600 tons burthen, has been named *The Clyde*, and is described as having a most perfect model. Her engines, made by Messrs. Caird and Co., are in readiness, and will be put in without delay. There are at present six of this line of packets, all of the same tonnage, building on the Clyde, four at Greenock, one at Port-Glasgow, and one at Dumbarton; and there is also one at Leith.—*Glasgow Argus.*

REVIEWS.

The Competition for the Nelson Monument critically examined. By John Goldicutt.

Thoughts on the Abuses of the Present System of Competition in Architecture, with an outline of a Plan for their Remedy: in a letter to Earl de Grey. By Harry Austin.

Perhaps no instance that has ever occurred, has shown the utter worthlessness of competition, under the present system, in so strong a light as that for the Nelson monument. The usual cases of fraud and imposition got up by parish officers and attorneys to extract designs from architects without undergoing the ceremony of paying for them, carry each its own stigma; but here is a competition established by a committee of men of unimpeachable integrity, with a sincere desire to elicit a design worthy of the nation, and what is the result? According to the opinion of an honourable and influential member of the committee, Lord Colborne, "there was not a single model or design that came up to what might have been reasonably anticipated, or which would justify the committee in selecting it as a fit and proper monument for so great a man as the hero whose achievements they were anxious to celebrate." Rotten must be the system which could produce such a result under such circumstances, if this judgment were true, or which could permit it, if untrue, to pass without general reprobation; and be it remembered, that the censure includes the design chosen, and now in progress of execution.

It is impossible to deny that the exhibition of the hundred designs and upwards submitted to the committee, was any thing but creditable to the state of British art, and such will be the character of all such exhibitions, as long as a system, or a want of system, is pursued which tends to keep every man who respects himself out of the field. It is certain that a very small proportion indeed of the artists who entered into the Nelson competition were of that class which the committee intended to encourage, and who might have been successfully encouraged with very little trouble; and of those few there is not perhaps one who has not sighed over the loss of his time and labour, which he might have assured himself before-hand would be thrown away. Here is Mr. Goldicutt, for example, who gives us a Jeremiad on the injustice of the Nelson competition. The question is obvious, why had he any thing to do with it, and what did he expect? Did he shut his eyes, his ears, and his understanding to all that was going forward long before the designs were received? Did nothing strike him as deficient or contradictory in the conditions and instructions put forth by the committee, which might have led him to suspect they did not quite understand their own meaning or know their own intentions: or to doubt their competency for what they had undertaken; or did it not occur to him that they had neglected the most ordinary precautions to assist their judgment and to secure fair play to the candidates? and did he make no inquiries to satisfy himself on these points? If he did not, others did, who found their remonstrances and suggestions rejected with the most self-sufficient obstinacy, tempered, it is but just to add, by the utmost courtesy to all applicants on the part of Mr. Scott. And then, why, in the name of common justice, were the competitors encouraged to exercise their invention through every conceivable modification of public memorial, from a simple statue to a full grown temple of Victory, when it was as notorious as the sun at noon day that nothing but a column had the remotest chance of acceptance. Enough had been said at public meetings by the most influential promoters of the scheme, to satisfy any one possessing an average share of observation, that the current set in that direction too strongly to be turned. Why, therefore, did Mr. Goldicutt take the trouble to deliver himself of what he might be very sure would be strangled for a monster in the Foundling Hospital to which it was to be consigned? Upon the taste or wisdom displayed by the committee in deciding upon a column in general, or on Mr. Railton's column in particular, or on any design at all if they were all so bad as Lord Colborne would persuade us, there is no occasion to give an opinion. Whether we consider a column the best of all possible monuments, and Mr. Railton's the best of all possible columns, or maintain the very reverse, in no way affects the conclusion—that gross mismanagement produced a result which seems to have astonished the committee, though it could produce no other, and that a great injustice was committed in not ascertaining beforehand, what was perfectly notorious, that the accepted design would be a column and nothing else, and issuing instructions accordingly. Those who play so recklessly with the labours of architects ought to consider that life is short and drawing paper dear.

For the mischiefs which arise to the profession and the public from the disgraceful state of competition, Mr. Austin steps forth with a string of remedies, every one more futile and inefficient than another, the grand nostrum being that the whole conduct of competitions should be placed under the management of the Institute of British Architects—a proposal very complimentary to the Institute, and one which they would only be doing their duty and carrying out their professions by taking into consideration. But setting aside several objections which occur, it is only necessary to mention one which Mr. Austin seems to have overlooked, viz. that the plenary authority of the Institute must be first recognized by all concerned, or likely to be concerned, and unluckily the parties most dipped in competition (may they speedily have it all to themselves,) are precisely those who are most interested in maintaining the *status in quo*. Besides, suppose the most satisfactory arrangements to be established, no one would be bound to abide by them, as Mr. Austin may see by reference to the Journal for October last, when he will find Mr. Serjeant Talfourd's opinion on the flagrant Bury St. Edmund's case. Nor is Mr. Austin more fortunate in his proposal that the author of a successful design shall, *in every case*, be intrusted with the superintendence of the building. What is to be done if a committee, acting *bonâ fide*, should pitch upon the design of an apprentice, an amateur, or a drawing clerk, or of one of that class of the profession (for, like the law, it is sorely infested with vermin,) who traffic in showy drawings and fraudulent estimates. And the fact is, that the designs of these classes of competitors (we beg to apologize to the three first for naming them with the last,) are precisely those best calculated to catch committees as they are for the most part constituted. Mr. Austin, indeed, goes in the very teeth of his own opinion in this proposal. "It is needless to say," he observes, in another place, "that those who send in designs honourably executed, alike fair to their brother competitors and to the committee, which they conscientiously believe can be built for the amount stated, are doomed to experience nothing but vexation and disappointment, and that if they could catch a glimpse of the committee in the very first hour of their sitting, they would most probably see them already sorting their modest designs from the showy and impossible draughts, and laying them aside with the flattering epithet of 'rubbish!'" This is perfectly true, and it is no less so that "the best chance of success under the present system rests with those who, knowing full well the utter ignorance of the men who are to decide on the real merits of the works laid before them, make this their stronghold and anchor of hope. They prepare designs on a scale of great magnificence, which, to carry out in their pristine grandeur, would cost twenty times the stipulated amount. They will be at considerable pains to render prominent the most striking portions of their designs, and to throw a veil over their various defects. They will employ skilful artists to prepare coloured showy elevations, and false perspective views of their principal features, to catch the Committee's unpractised eye; and knowing too well that these designs could not possibly be executed for any thing like the stated estimates, modestly assert, in their accompanying remarks, that much of what they show, (though all in all to their designs, such as they are,) might be omitted without the slightest injury to them. And the committee believe it, because they know no better."

"Is it not wonderful," we still use the words of Mr. Austin, "that so many should be found to engage in contests which experience teaches them are certain to be unsatisfactory and unjustly conducted." It is quite as wonderful that with so just an appreciation of the real state of competition, Mr. Austin should have gone so far wide of the mark in devising remedies.

Did the members of the profession never read the fable of Hercules and the carman? They are just now very much in the case of that same carman, shouting for help with all their might, but with less wit than the boor, for they do not know to whom they are shouting. We are nevertheless competent to give them the same advice that was delivered by the god—that each one should put his own shoulder to the wheel. Very deep they are in the slough, it is true, and a very filthy slough it is—so filthy that from mere communication the whole profession smells of it. Let every one who has not a taste for abiding in the dirt extricate his individual self, and keep cleaner ways for the future. To drop the metaphor, let every member of the profession who respects himself, resolve to enter into no more competitions, unless he is perfectly satisfied, after a strict examination, both with the conditions, and the integrity and competency of those who propose them, and let no one lose an opportunity of exposing in print every case of fraud and falsehood which may come to their knowledge. The example has been set in the pages of this Journal—let it be followed—and when the respectable classes of the profession are shamed out of promiscuous competition, and the public are awakened to the consequences, something may be effected to place the system, which nobody will deny to be thoroughly sound in its original principle, upon a satisfactory footing.—The following notice of a late trial will show how competition designs are often *got up*, but it is greatly to be lamented that committees are not often so competent and resolute in dealing with them:—

NORWICH ASSIZES.—*April* 7, 1841.

Brown v. *Langshaw*, Clerk.

Early in the year 1837, the parish church of St. Andrew the Great, Cambridge, was found to be in a ruinous condition, and a subscription was raised and a committee appointed for the purpose of rebuilding it. The committee applied to several architects for designs, and five were laid before them, among which that of Mr. Brown of Norwich, was conspicuous for its elegance and ornamental character—so much so, that the committee were not only greatly surprised at the high talent shown by Mr. Brown, in producing a design so superior to those of his rivals, and to any thing which had ever been imagined practicable for so small a sum as four thousand pounds, the limit set to the expenditure in the conditions accepted by the architects, but some of them also doubted the possibility of a *mistake* in Mr. Brown's estimate, an accident which does sometimes happen in affairs of this kind. As the architect professed himself to be perfectly clear on this point, his design was accepted and offered for contract. Several respectable builders of Cambridge having declined to compete, two tenders only were obtained, the lowest of which, instead of falling within four thousand pounds, amounted to something like six!—a dilemma which the architect was quite prepared to meet by altering his design so as to bring it within the prescribed limits. The majority of the committee (which was not composed exclusively of parish officers), being however troubled with a prejudice that such a course of proceeding might not be altogether just to the other parties who had expended their time and labour upon the faith of the conditions under which they were invited to compete, came to a resolution to dismiss Mr. Brown, who thereupon brought an action against the chairman, the Rev. Mr. Langshaw, to recover the sum of £300 and upwards, for preparing his designs. After keeping this action hanging over the heads of the committee for nearly four years, it has at length been tried as aforesaid, and upon the facts proved by the plaintiff's own evidence, the learned judge stopped the case, and a verdict was found for the defendant.

Observations on Railway Monopolies and Remedial Measures. By ALEXANDER GORDON, M. Inst. C.E. London: Weale, 1841.

Mr. Gordon is particularly known to the public for his great exertions for the introduction of the steam carriage on the common road, it is not perhaps so well known that he labours under a railway phobia, which is the cause of the production of the present pamphlet. This like all Mr. Gordon's works abounds with much that is valuable, but it is so tinctured with the expression of his prejudice against the railway system, that much of the weight of his remarks is counteracted. His zeal for the welfare of his profession is a prominent feature in his character.

Peckston on Gas-Lighting. Third Edition. London: Weale, 1841.

Mr. Peckston has been before the public for the last twenty years as a writer on this subject, so that we may fairly conclude that his merits must be pretty well known without any commentary of ours. We have now another edition of his work, embodying all the recent improvements, and abounding with all that extent of illustrations, which makes Mr. Weale's merits as a publisher of engineering works conspicuous. We do not recommend our readers to buy Mr. Peckston's book, because we know that if they want to acquire any information as to gas-lighting they must refer to him.

On Harbours. By W. A. BROOKS. London.

Mr. Brooks's work contains much that is new and valuable, it requires however more consideration on our part before we can adequately discuss the views put forward. In the meanwhile the engineering student may with advantage refer to this volume, which has evidently been written by a man of research and ability. It contains some good information as to the views entertained by French and Italian engineers.

A New Treatise on Mechanics. By the Author of a "New Introduction to the Mathematics." London: Whittaker & Co., 1841.

This is one of those laudable attempts to simplify a subject too often mystified, which is well deserving encouragement. The public are sure to gain by attempts of this nature, for though new errors may sometimes be introduced, more is gained by the removal of old ones.

Map and Section of the Brighton Railway. By J. R. JOBBINS. London: Grattan and Gilbert, 1841.

This map the scale of three miles to an inch, includes the whole of the Greenwich, Croydon, Brighton, Blackwall, West London and Thames Haven lines, the South Eastern to beyond Tunbridge, the Eastern Counties to Chelmsford, the Northern and Eastern to Broxbourne, the Birmingham to Tring, the Great Western to Maidenhead, and the South Western to Woking, with the country 25 miles north of London, 15 miles south, and 30 miles east and west, including the course of the Thames and the country between Windsor and Chatham. It seems to be executed with great accuracy, and for cheapness and extent of information is highly valuable, being equally useful either as a railway or general map. Appended to it are sections of the Croydon and Brighton lines, showing also by a novel plan the surrounding country.

Davies's Map of London and its Environs.

Mr. Davies's map includes all the recent improvements in the neighbourhood of London, giving the cemeteries, railway stations, and other matters. It includes the boundaries of the metropolitan borough, and much other useful information, so as to serve equally as a map of London and of the surrounding country.

MOTIVE POWER FOR IMPELLING MACHINERY.

Henry Pinkus, Esq., late of Panton-square, Coventry-street, but now of No. 36, Maddox-street, Regent-street, Middlesex, for improvements in the methods of applying motive power to impelling machinery, applicable, amongst other things, to impelling carriages and vessels, and in the methods of constructing the roads on which carriages may be impelled, enrolled March 24, 1841.

One of the improvements to which the patentee lays claim is what he terms the differential railway. It consists of a double line of railway, on which, at certain distances, is affixed a gas-explosive apparatus, described in the specification of a former patent obtained by him, provided with two large horizontal wheels, one above the other, round each of which an endless metal band passes; and between each apparatus thus described is an intermediate apparatus, provided also with a pair of wheels. The band proceeding from one of the horizontal wheels passes round one of the wheels of an intermediate apparatus placed in one direction, whilst the band from the other horizontal wheel passes round one of the wheels of an intermediate apparatus placed in the opposite direction.

The bands pass over wheels placed in the centre of each line of rails, and put those wheels in motion, which motion is communicated to the train of carriages by means of bars extending from the bottom of the same, and which are kept in contact with the wheels.

Another of the patentee's improvements is for a mode of propelling boats on canals by "gaso-pneumatic" power. Along the whole length of a canal, on one or both banks, a suspension rail is constructed, and along the canal, in a line with the rail, is laid down a gas main. On the rail is suspended an impelling machine, which consists of a frame running on wheels, and provided with two horizontal pulleys, round one of which an endless band passes from a pulley in the boat to be impelled, and in which is placed the gaso-pneumatic explosive engine. This engine actuates the pulley in the boat, which by means of the endless band communicates its motion to the horizontal pulleys, and they in turn communicate it to the running wheels, and cause the impelling machine to move onward and impel the vessel. Another mode of applying power on canals consists in using a steam engine in place of the gaso-pneumatic engine, to give motion to the impelling machine; and in order that boats may travel in opposite directions with only one line of rails, the impelling machines are made to move over one another when they meet, and so proceed on their respective courses.

The following is a mode of constructing roads or ways, also included in this specification:—In a given area of land a station is erected in a central situation, in which is placed an electric battery or batteries; or wells or tanks are constructed in any part of the said area. From the station, or from any of the tanks, a system of mains or pipes is laid down, and all along these, at intervals of from one to two hundred yards, are erected short vertical branches, terminating in a box with a moveable lid. In the mains are laid continuous metallic wires, and these wires are so arranged that when their ends at the station or tanks are brought into contact with the positive and negative poles of a battery, they constitute metallic circuits.

In order to put implements into action by means of this power, the patentee uses a locomotive engine similar to that described in the former specification, except that the cylinders, piston-rods, and their appurtenances are dispensed with, and the drum may be of smaller dimensions. Round this drum is coiled a pair of wires, and these are attached to a similar pair in one of the boxes before mentioned. To the locomotive engine an electro-magnetic engine is applied, and, in order to set the former in motion, chemical action is induced in the batteries at the station or tanks, and electrical influence is thus generated, the force of which, acting through the metallic circuit, will put the impelling engine in motion.

The patentee uses the electric power to prevent the collision of trains on railways, by causing it to put the breaks of carriages into action; he also attaches an electric battery to the locomotive engine, so that when trains are approaching each other, the battery being brought into action will, by means of connecting wires, apply the breaks, pull the lever of the whistle, and shut off the steam.

The patentee also shows a mode of constructing engines, and of actuating them by means of electric power.

The electric power is also used for lighting railways, tunnels, roads, &c.

An electric glow or "brush" is effected at the place required to be lighted, and being placed in the focus of reflectors, yields rays of light, which may be made revolving lights for night signals, &c.

In addition to the numerous improvements included in this specification, already noticed, there is one for a fire-engine to be worked by the "gaso-pneumatic power," to be drawn from the gas mains in the streets where the fire occurs, in the same manner as the water. [This specification occupies fifteen sheets of parchment, and there is also a corresponding number of drawings.] —*Inventor's Advocate.*

STEAM NAVIGATION.

THE NIGER EXPEDITION.

The expedition about to leave this country, to explore the River Niger, and which has excited such intense interest, consists of three iron steam vessels under the command of Captain Trotter, an intelligent and experienced officer of Her Majesty's navy. The two larger ones, the "Albert" and the "Wilberforce," are each of 410 tons burthen and 70 horses' power; and the smaller one, the "Soudan," (intended to act as a pilot vessel,) admeasures 250 tons, and has an engine of 35 horses' power. The two first are schooner rigged, and are remarkably fine-looking vessels, with lofty spars, and will display a large spread of canvass to the favouring breeze. They are fitted with Captain George Smith's method of stowing boats to form part of the paddle boxes, in addition to the usual complement of boats. They are heavily armed, and will each carry a number of Kroomen (a class of men accustomed to the climate, and found to be of eminent service), besides an efficient man-of-war's crew; and altogether, will prove formidable opponents should the natives venture to molest them, as they did the last expedition, under Messrs. Laird & Oldfield.

The interiors of the steamers are replete with every convenience, and even luxury, which can be desired. They are furnished with Dr. Reid's ingenious system of ventilating tubes (a kind of air filter) for the purpose of supplying fresh air in the 'tween decks; and which contrivance, it is confidently expected, will prove of great utility in protecting the crews from the debilitating effects of the noxious vapours which infest the vicinity of the River Niger, and which have hitherto rendered that climate so dreadfully fatal to Europeans. From their light draft of water they will be enabled to ascend a considerable way up the river, should they be so fortunate as to escape running hard aground, as from their great size it would be a difficult matter to get them off, especially should the crews suffer from the climate. The last expedition incurred great delays from the vessels continually getting aground; yet they were much easier got off than these would be from their being of smaller dimensions.

In conclusion we wish them every success, and must say that an expedition better calculated to fulfil its purpose never left the shores of this, or, indeed, any other country.

A comparison of the dimensions and draft of water of the steamers comprising the last and present expeditions, may afford an idea of the advanced state of steam naval architecture since the year 1832.

Last Expedition.			Present Expedition.	
	Quorra.	Alburkah.	Albert and Wilberforce.	Soudan.
Length	112 ft.	70 feet	130 feet	110 feet
Breadth	16	13	27	22
Depth	8	$6\frac{1}{4}$	10	$8\frac{1}{2}$
Horses power	40	16	70	35
Draft of water	6 ft	$4\frac{1}{3}$	$5\frac{3}{4}$	4
Built of	timber.	Iron.	Iron.	Iron.

The vessels of the present expedition were built by Mr. John Laird, of North Birkenhead, Liverpool, and the engines by George Forrester & Co., of Liverpool.

Auxiliary Steam Power.—We have to announce the departure for India, during the last month, of the "Isabella Blyth," a ship of 500 tons burden, fitted with a pair of small engines and paddle-wheels, to be used during calms and light winds, which, it has been ascertained on statistical data, prevail, on an average passage to or from India, during full one third of the time occupied by the whole voyage. To overcome this very serious difficulty, and ensure regular and rapid passages, the splendid class of vessels which now constitute our mercantile navy, appear to require nothing more than the successful application of steam power as an auxiliary. In order to prevent the great loss of power and increased liability to derangement resulting from one paddle wheel being immersed too deeply in the water when the ship is listed over, (while the other would consequently be entirely out of the water,) and also to elevate and depress the paddle wheels to suit the immersion of the vessel, which will, of course, vary not only with different descriptions of cargo, but also by the consumption of fuel, water, &c., during a voyage; the paddle wheels are fitted in such a manner that either wheel may, by the power of one man, be raised or lowered as occasion may require without stopping the engines. The greatest advantage will thus be taken of every breeze of wind, without any sacrifice of the auxiliary power. We feel assured that the ordinary paddle wheels which have, up to the present time, proved superior to every other propeller, only required this adaptation to render their application to sailing vessels perfect, and we therefore anticipate a very favourable result.

This vessel left the London Docks the latter part of last month, drawing 17ft. 6in. water, and after encountering more than the usual obstructions of the Pool, and proving in all her movements to be completely under the control of the steam power, the paddle wheels were adjusted to the proper depth of immersion, and the distance to Gravesend was performed in about four hours and a half. With the exception of a topsail being set during about twenty minutes, no advantage was taken of the sails.

Distinguishing Signal for Steam Boats.—We have been gratified, in common with a considerable number of steam-boat owners, captains, and others interested in steam navigation, by being shown a signal which will most admirably effect an object most desiderated, that of distinguishing steam vessels from sailing vessels at sea, and go far to prevent unhappy collisions and the destruction of human life. The inventor is Mr. Francis Melville, Buchanan Street, who, from a praiseworthy desire to promote the general safety, has devoted much of his time to the subject. Mr. Melville's plan is to place in front of the funnel of the steamer a lamp, with a clear light, and a strong reflector, having an external sliding cover attached to its face, so fitted as completely to obscure the light within, but to be made to move up and down the whole length of the lanthern, by means of a rod affixed to a small lever power connected with the engine, so that the motion or alternations of the slider would be at the rate of twenty in a minute. At the bottom is to be added a flat sole, made so as to carry the rays of light completely over the side of the vessel, in order that the reflection from any object on deck may not interfere with the pilot. By means of this simple apparatus, a signal will be produced perfectly distinct from any other known in navigation, and by means of it a steamer will, at the first sight, be known from any other vessel. Though the exhibition which we had the opportunity of observing was necessarily imperfect (being displayed from a window), enough was, nevertheless, witnessed to show at once the perfect practicalality and adaptation of the signal to the purpose intended.—*Glasgow Argus.*

Sixteen war-steamers are ordered to be built, six of the first class and ten of the second; all to be armed with guns of 10 inch calibre. Several of these will be laid down immediately, and the frames of the whole converted without delay, so as to be ready against the engines are prepared.—*Naval and Military Gazette.*

The Royal West India Steam Navigation Company have resolved to build six additional steamers. From the high recommendation given to the Clyde ship-builders by the Government inspectors, who have inspected the steamers now on the stocks, we understand that a few, if not the whole, of the additional steamers will be constructed on the banks of the Clyde. Three additional steamers are about to be contracted for by the Cunard Atlantic Steam Company.—*Glasgow Chronicle.*

The Mammoth, building by the Great Western Ship Company, at Bristol, will exceed 3,600 tons (about 600 more than any other ship in existence). The saving of room by her being built of iron will admit of her carrying coals for both the outward and home voyages, a matter of much importance from the inferior quality of American coal. Her engines are of 1,000 horse power. She will be enabled to carry an unusual quantity of canvass, and is expected to make the passage of the Atlantic in ten days.—*Liverpool Advertiser.*

MISCELLANEA.

The Duke of Wellington's Statue.—This colossal equestrian figure is rapidly progressing under the hands of Mr. Wyatt. When completed, it is expected to weigh about 50 tons, and to stand about 32 feet from the pedestal. If possible, it is to be formed entirely of the cannon taken by his Grace. The model of the horse, which is about half finished, is very fine. The gigantic animal, with eyes extended and nostrils inflated, is breathing with animation and vigour. The head and boots of the Duke are already cast. The face is an admirable likeness, as is well known to all who had an opportunity of seeing the model of it last year. These parts of the figure, which are all at present completed, have taken the metal of a single cannon. The lower extremities of the figure will be of solid bronze, the thickness grapually diminishing in the upper parts. It is said that the committee have appointed two years as the period in which the work should be completed, 11 months of which have already transpired, but it seems almost premature to fix a time for the finishing so elaborate and gigantic a work, especially when the process of casting is attended with so many risks that may cause a temporary impediment to its progress. During his labours Mr. Wyatt has acquired much valuable experience calculated to advance the art of casting in metal, among which are a method for testing the tubes which supply the metal to ascertain that they are perfectly clear, and a plan with the air tubes that causes them not only to expel the air, but also to operate as suction tubes to the metal, and promote its distribution. Another ingenious contrivance is a set of instruments, invented by Mr. Wyatt, for clearing off the metal with infinitely less labour than a common hand-instrument. This Wellington statue, when finished, will, it is supposed, be the largest hitherto known.

Primrose Hill, Regent's Park.—The Commissioners of Woods and Forests have, we understand, concluded an arrangement with Eton College, by which Primrose-hill will be preserved from being built upon. This place of healthful resort will therefore remain to the inhabitants of the metropolis, as one of the "lungs of London."

Artesian Well at Southampton.—The works on this important and spirited undertaking have been resumed; but after working one of the engines some ten hours, an accident occurred by the breaking of the fly-wheel shaft of the north engine—the cause of which it appears is not as yet accounted for. It seems that by the present arrangements immense quantities of water can be raised from the shaft to the surface, as, with only one engine and one pump at work, and those working only at one half the speed to which the engine is equal, the quantity of water delivered from the pump nozzle exceeded 12,000 gallons per hour; and this, too, when the water to be raised was upwards of 150 feet from the surface level. The present depth of the shaft is 300 feet, the excavation for a large portion of which is upwards of [illegible] feet diameter. We have reason to believe that for the purpose of obtaining a supply of water, there has been no other shaft constructed of so large a diameter, or with such durable material, or so great a depth. The difficulties encountered in sinking the shaft thus far have been of no ordinary kind, notwithstanding which, no one engaged in the undertaking appears to be discouraged. On the contrary, each misfortune appears to excite fresh exertions. The commissioners and contractors have decided to sink the shaft to a much greater depth, which, in our opinion, is far preferable to the plan of boring to so great a depth as was originally intended. We heartily wish the undertaking every success, but whatever the result may be, the inhabitants of Southampton will, by this work, solve the important problem, whether or not a copious supply of good water can be obtained by sinking a capacious shaft in a site so geologically situated as is their increasing town, and as is also similarly situated the great metropolis with its suburbs.—*Hampshire Independent.*

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 29TH MARCH, TO 27TH APRIL, 1841.

Six Months allowed for Enrolment.

JAMES TILDESLEY, of Willenhall, Stafford, Factor; and JOSEPH SANDERS of Wolverhampton, Lock Manufacturer, for "*improvements in locks.*"—March 29.

GEORGE EVANS, of Dorset Place, Marylebone, for "*an improvement or improvements upon trusses, for the relief of hernia.*—March 29.

ALEXANDER PARKES, of Birmingham, Artist, for "*certain improvements in the production of works of art in metals, by electric depositions.*"—March 29.

JOHN LINDSAY, of Lewisham, Esquire, for "*improvements in covers for water-closets, night-stools, and bed-pans.*"—March 29.

JAMES FURNIVAL, of Warrington, Carrier, for "*an expeditious mode of unhairing, mastering, and tanning various descriptions of hides and skins.*"—March 29. (Four months.)

THOMAS GORE, of Manchester, Machine Maker, for "*improvements in machinery or apparatus for roving, spinning, and doubling cotton, silk, wool, and other fibrous materials.*"—March 30.

JOHN ORAM, of Chard, Somerset, Machinist, for "*improved machinery or apparatus for making or manufacturing netted fabrics.*"—March 31.

WILLIAM JENKINSON, of Salford, Machine Maker, for "*improvements in machinery for preparing and spinning flax, silk, and other fibrous substances.*"—March 31.

JOSEPH GAURY, of Watling Street, Warehouseman, for "*a parachute to preserve all sorts of carriages using axletrees from falling or injury, upon the breaking of their axle-trees.*" A communication.—March 31.

JOHN GEORGE BODMER, of Manchester, Engineer, for "*improvements in the construction of screwing stocks, taps, and dies, and certain other tools or apparatus or machinery for cutting and working in metals.*"—April 3.

JAMES OGDEN, of Manchester, Cotton Spinner, and JOSEPH GRUNDY WOOLLAM, of Manchester, aforesaid, Commission Agent, for "*improvements in looms for weaving.*"—April 3.

WILLIAM EDWARD NEWTON, of Chancery Lane, Civil Engineer, for "*improvements in the process, mode, or method of making or manufacturing lime, cement, artificial stone, and such other compositions, more particularly applicable for working under water, and in constructing buildings and other works which are exposed to damp.*" (A communication.)—April 3.

ZACHARIA BRYANT, of the town of Nottingham, Machinist, for "*an improved method of manufacturing cloth and other fabrics from woollen, cotton, flax, silk, and other substances.*"—April 3.

JAMES ANDERSON, of Newcastle-upon-Tyne, Engineer, for "*improvements in windlasses.*"—April 5.

WILLIAM JAMES BARSHAM of Bow, Gentleman, for "*improvements in fastening buttons and other articles on to wearing apparel, and other descriptions of goods or manufactures.*"—April 5.

HENRY M'EVOY, of Graham Street, Birmingham, Hook and Eye Maker, for "*improvements in fastenings for bands, straps, and parts of wearing apparel.*"—April 5.

JONATHAN BILEY, of York, Brewer, for "*improvements in brewing.*"—April 5.

WILLIAM HUTCHINSON, of Sutton and Trent, Nottingham, Seed Crusher and Oil Cake Manufacturer, for "*improvements in the manufacture of oil-cake or seed-cake.*"—April 5.

WILLIAM LITTELL TIZARD, of Birmingham, Brewer, for "*improvements in apparatus for brewing.*"—April 5.

JOSEPH WILSON BUTFALL, of Belper, Draper, and HENRY HOLDER, of the same place, Tailor, for "*improved apparatus to be attached to trowsers, commonly called trowser-straps.*"—April 5.

JOSEPH APSEY, of Cornwall Road, Engineer, for "*improvements in the construction of flues for steam-boilers and other furnaces.*"—April 6.

CHRISTOPHER EDWARD DAMPIER, of Ware, Gentleman, for "*improvements in weighing-machines.*"—April 15.

FRANK HILLS and GEORGE HILLS, of Deptford, Manufacturing Chemists, for "*improvements in the manufacture of sulphuric acid and carbonate of soda.*"—April 15.

HENRY AUGUSTUS WELLS, of Saint John's Wood, Gentleman, for "*improvements in the manufacture of woollen cloths.*"—April 17.

PETER KENDALL, of Gifford's Hall, Suffolk, Esquire, for "*an improved method or methods of connecting and disconnecting locomotive engines and railway carriages.*"—April 17.

JOSEPH BARKER, of Regent Street, Lambeth, Artist, for "*improvements in measuring æriform or fluid substances.*"—April 20.

JOSEPH BENTHAM, of Bradford, Weaver, for "*improvements in weaving.*"—April 22.

HENRY BROWN, of Codnor Park Iron Works, Derby, Iron Manufacturer, for "*improvements in the manufacture of steel.*"—April 22.

THOMAS HARRIS, of Hales Owen, Birmingham, Horn Button Manufacturer, for "*improvements in the manufacture of what is called horn buttons, and in the dies to be used in the machinery of such descriptions of buttons.*" (Partly a communication.)—April 22.

HUMPHREY JEFFERIES, of Birmingham, Button Maker, for "*improvements in the manufacture of buttons.*"—April 22.

JOHN ROSTRON, of Edenfield, Lancaster, Manufacturer, and THOMAS WELCH, of Manchester, Manufacturer, for "*improvements in looms for weaving.*"—April 22.

FLORIDE HEINDRYCKX, of Fenchurch Street, Engineer, for "*improvements in the construction and arrangement of fire-places and furnaces, applicable to various useful purposes.*"—April 24.

LANCELOT POWELL, of Clydach Works, Brecon, Ironmaster, and ROBERT ELLIS, of Clydach, aforesaid, Agent, for "*improvements in the manufacture of iron.*"—April 24.

THOMAS ROBINSON, of Wilmington Square, Gentleman, for "*improvements in drying wool, cotton, and other fibrous materials in the manufactured and unmanufactured state.*"—April 27.

WILLIAM PETRIE, of Croydon, Gentleman, for "*a new mode of obtaining motive power by voltaic electricity, applicable to engines and other cases where a motive power is required.*"—April 27.

ALEXANDER SOUTHWOOD STOCKER and CLEMENT HEELEY, both of Birmingham, Manufacturers, for "*improvements in patten and clog ties, and other articles or fastenings of dress.*"—April 27.

BENJAMIN RANKIN, of College Street, Islington, Gentleman, for "*a new form and combination of, and mode of manufacturing blocks for pavement.*"—April 27.

OSBORNE REYNOLDS, of Belfast, Ireland, Clerk, for "*improvements in paving streets, roads, and ways.*"—April 27.

ANDRE DRONOT DE CHARLIEN, of Coleman Street Buildings, Gentleman, for "*improvements in preparing matters to be consumed in obtaining light, and in the construction of burners for burning the same.*" A communication.—April 27.

TO CORRESPONDENTS.

Maplin Lighthouse appeared in the last month's Journal.

Steam Engines in America will appear next month.

We are compelled to postpone several papers until next month; we must earnestly request of our numerous correspondents to favour us with their communications as early in the month as they possibly can, so as to ensure insertion.

Warming Buildings with Warm Water.—*We have received a communication from Mr. Richardson, and also an answer by Mr. Perkins to Messrs. Davies and Ryder's Report, given in last month's Journal, we very much regret that we are compelled to postpone both of them. We do not think it exactly correct to attack the report, until the experiments promised by Mr. Perkins are tried, we shall feel much pleasure in attending such experiments, and giving a faithful report of them, as we consider it a question of such great importance that it ought to be decided by facts and not by arguments.*

Communications are requested to be addressed to "The Editor of the Civil Engineer, and Architect's Journal," *No. 11, Parliament Street, Westminster.*

Books for Review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume.

It will not diminish the interest of the subject to our readers to know that, in his "Spas of Germany," Dr. Granville speaks of the *Kursaal* at Brückenau, in the following highly complimentary terms. "This is another of the great architectural works of which Bavaria may well be proud, and the idea and design of which were suggested by the King himself. It is the handsomest building of the kind I have seen in my general excursions in the Spas of Germany, and its various decorations are equal to any of the most exquisite productions of the Bavarian artists. On the right a grand flight of stairs leads to the king's gallery. The pavement is tessellated, and the *plafond* richly painted in stucco. From it depend five gigantic lustres which are said to give to the interior, on gala nights, the splendour of sunshine, lighting up every part of a building which for loftiness, daring proportions, and dimensions is such as an English people seldom witness in their public edifices. It is the production of Gutensohn,* a native of Lindenau in Switzerland, who having shown when very young, and at Munich, a considerable taste for architectural drawing, the King of Bavaria sent him at his own expense to Italy and Greece, to complete his studies. He is now residing at Wurzburg, and is employed in public works on account of the crown. I did not ascertain what such a public building might have cost in Bavaria, but it would be easy to calculate what sum would have come out of the Exchequer in this country, were such a one to be attempted."

So far the Doctor,—who at the time he wrote his description, had no idea that it would be tested by being confronted with any drawings of the edifice itself, or he would probably have expressed himself rather more cautiously, for as far as mere design is concerned, there certainly is nothing remarkably striking in the exterior of the building: it is in a good though simple style, and possesses a certain propriety of character; besides which it has the advantage of being insulated, and of strict consistency being kept up in every one of its elevations. It should also be borne in mind that much of the effect attending the building itself—of the play of perspective and of light and shade produced by the open arcades enclosing the whole of the lower part above the basement,—is necessarily lost when the design is exhibited only in separate geometrical drawings. On the other hand, we are of opinion that consistency and uniformity have been pushed somewhat farther towards monotony, than there was any occasion for; and that the design would have been improved by having a little more variety thrown into it. Neither is the building at all remarkable for its size, the extreme dimensions being only 112 by 165 feet English.

In fact we must presume that Dr. Granville's admiration was excited chiefly by the interior and the style of its decoration, but we think that he has there also a little magnified some circumstances,—for instance when he tells us of a grand flight of stairs leading to the king's gallery; because the plan shows that staircase (*g*) to be a very confined space. Still there is undoubtedly much architectural grandeur and considerable scenic effect in the *Saal* or saloon itself, which rises the entire height of the building, and which may be said to occupy nearly the whole of the ground floor, the *Tanzsaal* or ball-room being in continuation of the other, though less lofty, and divided from it only by an intermediate compartment (*e*) having three open arches towards either of the other rooms. The decorations of the larger saloon, which is used as a dining or banqueting room, and of which a large perspective view is now lying before us, exhibits a tasteful application of the Renaissance style, or rather that of the Loggie of the Vatican. The deep and spacious royal tribune or loggia which is seen through three open arches in the upper part of the saloon, must have a strikingly splendid and scenic effect. As regards this portion of the interior, generally, we are of opinion that it contains much which would be exceedingly appropriate and applicable for the interior of an Exchange, with a covered area, lighted from above through a series of lunettes or semicircular windows (which might be left unglazed) just below the ceiling.

To quit these remarks of our own—which ought perhaps rather to have followed than preceded explanatory description, we return now to the latter. The building, begun in 1827, and completed within four years, stands upon a gentle declivity, in a beautiful valley, at no very great distance from the mineral spring, and from the baths and lodgings for visitors at the Spa. The edifice is raised upon a stylobate or low rusticated basement, containing the kitchens, cellars, and other offices, with the requisite accommodation for the domestic part of the establishment; which rooms are about 12 feet high, the floor being about four or five feet lower than the ground level. A flight of steps (*a*) at each end or front of the building leads up to the open loggia which forms a covered terrace quite around it, where the visitors can promenade, and enjoy the surrounding scenery. This loggia (*b b*) consists externally of 46 arches—viz. 14 on each of the longer, and 9 on each of the shorter sides or fronts,—and internally of 42 square compartments covered by as many small segmental domes. The larger Saloon or Dining Hall (*d*) is 54 feet (English) square, and 44 high: and its ceiling which is flat, has a cove intersected or divided into spandrils by the lunettes or arched spaces over the upper windows groining into it. Both the ceiling itself and those spandrils are richly decorated, as are likewise the panelled pilasters between the windows and upper arches, and also the podium upon which they rest. In its lower part or floor-plan, this Hall is greatly extended by the recesses or additional compartments, with which it is connected by three open arches on each side, and including which the dimensions become 88 feet English in the longitudinal, and 82 in the transverse direction of the plan. The *Tanzsaal* or Ball-room (*f*) measures 56½ by 30 feet, or including the recesses at its ends, the total length is 80½ feet. This room is very differently proportioned from, and by no means so lofty as the other (which approaches to a cube), the height here being 26 feet, or 18 less than that of the other.

* Johann Gottfried Gutensohn was born at Lindenau, on the Lake of Constance, in 1792. In conjunction with Knapp, he published a work on "Basilicas," 1822-6; and afterwards with Thurmer, another on the Italian architectural decoration of the 15th century. In 1832 he proceeded to Greece, as architect to King Otho.

The exterior of the building is entirely of wrought stone, of a quartz-like species, and of an exceedingly hard kind. Taken therefore altogether,—considering the solidity of its construction, the regularity of its design, and the richness of its internal decorations, this edifice is a very superior one of its class, and although of no very great extent, fairly deserves to be considered as a "monumental" production of the art.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXVII.

> "I must have liberty
> Withal, as large a charter as the winds,
> To blow on whom I please."

I. Seeing what Mr. Barry has done in the two Clubhouses designed by him in Pall Mall, methinks people might by this time perceive how much more might be accomplished by carrying on to a greater extent the same mode of treatment, and making the dressings to the windows not only finishings to those apertures, and proportioned to them, but so to be in a manner proportioned to the whole design, and to become important decorations of it. At present, though their mouldings may occasionally be richer than usual, there is little variety in the design of windows—little at least, in comparison with what there might be,—as regards composition and general character, such dressings consisting of no more than an architrave around the aperture, surmounted by frieze and cornice—either with or without the addition of pediment; or if something more than this be required, it is obtained by either small columns and pilasters. Yet wherefore should we confine ourselves to that as the very *maximum* of decoration allowable for such features, when window-dressings may be treated arbitrarily, that is, with artistical freedom instead of being invariably only the *echoes* of the parts belonging to a large order? Of course, one objection will be that they cannot be at all exaggerated without producing heaviness; another that the doctrine of arbitrary treatment, is nothing more than that of universal license—which would soon be universal architectural licentiousness. But according to the first objection, the cornicione of the Reform Clubhouse, ought to be offensively heavy, for it certainly may be characterized as being exaggerated. And with regard to the second, it would be better to run the risk of being scandalized by a little licentiousness in design now and then, out of fear of it—than to doom ourselves to what, if not exactly monotonous insipidity, excludes a great deal that would be good though of a different kind of merit. Most assuredly there is no danger whatever of our Anglo-Athenian school falling into any excesses as regard the decoration of windows or any thing else. No need to caution them against giving the reins to their imagination, and indulging in architectural frenzies. Their buildings may be chaste—for as the man said of his Aunt Deborah, they are so confoundedly prim and ugly that their chastity is proof against all suspicion.

II. Theodore Hook seems to entertain about the same kind and degree of affection and admiration for Railways, as I myself do for Palladio, or *caro mio* Bartholomew does for architectural competition. Whenever he can, Hook is sure to have a slap at the unfortunate Railways: witness among other instances the following comparison:—"it must as inevitably annihilate their hopes as the *incidental* tumble of a train off the railway settles the fate of the infatuated passengers of the iron hearses invented for the purpose of cheatery and monopoly, to supersede good old English horses and carriages, and the best roads for travelling in the world"! Most undoubtedly travelling by those 'iron-hearses' is not quite so aristocratic, dignified and luxurious as posting a journey in a chaise and four, preceded by a courier; still for the million the newer system has doubtless its advantages—vulgar ones though they be—or it would never have been encouraged to the extent it now is. When people can afford it, it is all very well for them to give themselves as many consequential and impertinent would-be-fine airs as they please; but is not Hook himself the driver or *conducteur* of a literary omnibus, started professedly *pro bono publico*, and always ready to *take in* and to be taken in by as many readers as it can obtain—the more the merrier?

III. S. L. has my hearty leave to inveigh against the application of Gothic to modern domestic buildings, if by Gothic he understands such frightful absurdities as was the so-called Gothic Dining-room at Carlton House, which had a flat ceiling—painted to imitate sky and clouds—just over one's head, and ugly brackets for lamps attached to it! It is said that that more astonishing than admirable specimen of taste was concocted by the united genius of George IV. and Messrs. Nash and Soane. What a triumvirate of talent!—worthy of Bartlemy Fair. Never was man more innocent of any feeling for grandeur in architecture than was that his 'Most Gracious Majesty.' There certainly is no royal road to taste; but then if he happens to have none himself, a prince should know where it is to be purchased ready-made, and take care that he be not imposed upon by Brummagem counterfeits,—and poor John Nash's taste was Brummagem to a degree it is now most mortifying to reflect upon. The time—so we are assured—will come when Brummagem alias Buckingham Palace, will have justice done to its merits; which time will arrive when it is pulled down, and not a day before. There is indeed one purpose to which it might properly enough be converted, viz. to that of a Royal Nursery, because in such a case the babyishness of its architecture would be in character.

IV. By no means is it uncommon to hear sneering remarks on the folly of those who build beyond their means, yet for one man of fortune who so dips his property, there are fifty who impoverish or embarrass themselves by other extravagances of various kinds, which escape censure either because they are more like the follies of other people, or because instead of showing themselves to the world as a single *corpus delicti*, they are a legion—inconsiderable when taken separately, although collectively most formidable. After all there may be a great deal of what the world calls extravagance, combined with true economy, and *vice versâ*. Our own times afford a splendid instance of what may be accomplished by magnificent economy. See what Louis of Bavaria has done for Munich, and for every branch of the fine arts in that petty capital! In this country had it been proposed to do but half as much, people would have cried out, Impossible! Had John Bull been asked to furnish two millions for a royal palace that would have been an honour to the nation, John would have turned confoundedly sulky, and buttoned up his breeches pocket in a huff. However John is liberal in his way, and also likes a bargain, therefore does not grudge half that sum to erect what is a disgrace to the country; flattering himself all the while, poor dupe!—that whatever be said of his taste, he is most certainly a pattern of economy. 'Two millions,' it must be confessed, has a most awful and startling sound upon such an occasion, but of the plurality of millions which leak out by perpetual droppings and drippings no account is taken. Could we but see the sum total of what has been squandered away at different times on paltry knick-nacks and ephemeral gewgaws,—on Kew Palaces and Carlton Houses,—on fetes, fireworks and other solemn tomfooleries, we should stand both aghast and abashed. But even were it doubled, that tremendous sum would not have been expended in vain, if it had purchased us a knowledge of true economy and wisdom for the future. Unfortunately, we seem to have very wrong-headed notions of economy, generally contriving to be at once shabbily penurious and recklessly extravagant in our public undertakings. As regards private economy we are not always very much wiser. However I will not go into that subject, further than to illustrate my text by the following short dialogue between two young men whose allowances were nearly the same. 'I cannot for the life of me, understand,' said one, 'how you possibly contrive to buy so many splendid publications, prints and pictures, I'm sure I can find money for nothing of the kind.'—'So I suppose,' replied the other, 'but then, my dear fellow, you have the satisfaction of knowing that you spend quite as much or more, on cambric handkerchiefs and kid gloves.'—Ah Johnny Bull, Johnny Bull, it is the cambric handkerchiefs and kid gloves,—the expensive fripperies of the day and the hour, that run away with your cash, and leave you none to patronize and advance art. Wastefully profuse in trifles, you generally show yourself exceedingly stingy where extravagance would be rather a virtue than a fault; or else you suffer yourself to be egregiously taken in under the idea of getting 'a capital bargain!' And it is fortunate if your bargains do not make you the laughing-stock of all Europe.—I declare I am growing quite patriotic!

V. Continuing the subject, it may be observed that our merchants do not emulate those of Florence and other Italian cities during their palmy state, in the encouragement of architecture and its sister arts. Is it because they cannot afford to erect noble palazzi and stately mansions?—And yet there are many among them to whom the price of such an edifice as the Reform Clubhouse would be a mere bagatelle. Some of them may be extravagant enough, but there is nothing magnificent in their extravagance. The money goes, perhaps, fast enough, but it goes vulgarly,—in eating and drinking,—in giving expensive entertainments to people who will *condescend* to be seen at them, pinching their pride for the sake of filling their bellies with the luxuries of a citizen's table. Or else the money does not go at all, except that it is let to go on accumulating until some '*beau matin*,' as the French say, the newspapers inform us that Mr. Snobbs or some other indefatigable money-grubber, like the Shoemaker of Bishopsgate

Street, is just dead, and has left property to the value of nearly one million sterling: *sic transit gloria mundi*.—I declare that I am getting quite edifying.

THE PALLADIAN SCHOOL OF ARCHITECTS.

Associated with the Palladian architects, is a name deservingly worthy of mention, for it is that of Kent. The taste of this ingenious artist, found, as it is, in the English mansion and in the palaces of the great, charms us at first by its luxuriance, and then leads us to closer inspection, from a certain correctness of feeling aptly displayed. His claim to this fellowship with the Palladian school rests upon the felicitous manner in which he caught its sentiment, and the rich and varied assistance he threw into the Palladian structure. Confining his efforts more to fancy than to skill, subduing his proportions more for the eye than for utility, he comes before us as the artist rather than as the architect, lavishing his exuberant ideas upon an interior, and unfettered by the many annoyances to taste which the calculating architect feels. There is an air of poetry in his conceptions admirably adapted to soften and to please; forms of carelessness and ease crowd around to soothe the wealthy inmate: there are the gleanings from nature appreciated by all, and there classic forms and allusions appear to enchant the refined.

Kent was one of a class who are lovers of antiquity, and over whose minds its wonderful creations act like a charm, and in whose hearts its beauties feed a passion. We find such painting the sky and peopling it with angels; throwing upon the walls figures of elegance, quaintness or dignity; carrying the whole harmony of a design into the saloon or gallery, and scattering it amidst an assemblage of forms without perplexing any: making the design to appear conspicuous and happy, even when associated with the noble, free, and graceful outlines of the sculpture.

I have placed Kent thus soon in the list of the artists of his school, from the necessity there appears to be to introduce to the notice of the influential, men of his particular stamp of genius. Not so much to criticise the excellencies of design, as to hint at the talents of many, gifted as he was, who are forgotten or despised, in the rush after foreigners. It would be well for the sapient, spectacled virtuosi (who sniff talent from the south long before the genius of their choice is born), if they would take their cold, starch, accommodating fancy into some of the mansions graced by his free yet careful hand. Why do the fraternity hesitate to patronize native genius? Why do these gentlemen, whose very fancy comes, like mushrooms, out of impurity, turn their squeamish patronage elsewhere? There must be some miserable prejudice afloat in the world of art, arising out of pedantry, and inflated efforts after imitation, to account for this. It must be that certain cold natures turn southward, or abroad, conscious of their own frigidity and death-like fancy; but it is not that there is no genius, native to all that is beautiful and fair, that these ghost-like Mecænases hurry about, like unquiet spirits, for their favourite.

Oh, when shall this age of precedent form a school of its own? when shall architecture and her sister arts be found linked in the embrace of nature, when shall Englishmen incite their countrymen to zeal, and art glow with the colouring of health and truth? It is no mean and trivial thing to design an interior. The very consciousness of entire freedom, leads a poor artist into profuseness, and if he seeks a relief by subduing a part, the meagre and shallow forms that appear attest his poverty of mind. The aim in the interior is opposed in every sense to the exterior, at which the passer by is to be arrested, and from which he is to judge of the pomp or dignity of the inmate. In the interior, the *pleasure* of the inmate has to be sought, and the artist has to borrow from the treasury of his fancy, every device which can divert and tranquilize. Through the contemplation of these the mind must unbend and relax into tranquil pleasure. How rich, then, and varied in its conceits, how sensitive in its structure, how refined and delicate, how acute in its parts, must be that mind which can conceive and execute a design so potent in its effects. It is not mere imagination, it is more; it is the imagination cooled and schooled, training its active and perpetual creations according to principle and rule, until it form a picture faithful and real, the original materials of which are in nature. It is not mere fancy either which admires the production, it is rather the fancy compelled by a skilful adaptation from nature of proportion, harmony, and grace, and which is, in truth, the mind affected under a *familiar* not an *artificial* influence.

Hence those artists who sport with flowers, and who fling, with a seemingly careless hand, into design the lighter beauties of their art, deserve attention, and deserve too, the same protection, assistance, and name, as Kent received; but whose talents must droop and wither so long as art holds in her body those worms that gnaw away her sickly vitals.

May 10. FREDERICK EAST.

ARCHITECTURAL ROOM, ROYAL ACADEMY.

We will dispense with further animadversions on the accommodation afforded to, or rather, withheld from, this department of the Academy's annual exhibitions; not because the slightest improvement in that respect has taken place—not because there is no longer any occasion for the observations we have already made at different times, but because they may be repeated 'till farther notice,' as the playbills say,—that is, to the end of the chapter, and until the Royal Academy, painters, architects, and all shall have become *Faimus Tro*—.—And truly, if architects themselves generally, and the Professor of Architecture in particular, can patiently tolerate a system which produces to them an annual insult, we do not see why we should allow ourselves to be at all ruffled and put out of temper by it. Patience and long suffering are no doubt virtues, and accordingly, as far as the Academy is concerned, architects show themselves the most virtuous of the human race;—not but that there are bounds even to patience, and if pushed beyond them, the illnatured world are apt to call it sheer dullness and stupidity.

In regard to the actual contents of the Architectural Room this season, we regret to find so very few designs for buildings of any promise or importance, among those either in actual progress, or definitively determined upon. We see many competition drawings, but then they are for the most part only rejected ones, while those which are adopted are kept back. For the Assize Courts at Liverpool, there are no fewer than ten different designs—some of them rather indifferent ones—including the successful one by Mr. Elmes, jun. But all of them are now, it seems, set aside, it being now intended to comprise the Courts and the St. George's Hall in one building. We will, however, first pay our respects to the Professor of Architecture, who modestly contents himself with exhibiting a single drawing, and that of a rejected design,—viz. No. 993, described in the catalogue as "A Study for a Front of a Public Building," which turns out to be neither more nor less than his design for the West Front of the Royal Exchange, engravings of which were published some few months ago in the Westminster Review. It certainly is not deficient in richness, and has the merit of avoiding that now common-place feature, a portico treated without any kind of originality, and brought in for the nonce, whether there be any thing else to agree with it or not. Still, it appears to us, keeping has not been sufficiently attended to, there being a disproportion between the large parasite columns and the rest, for not only do they overpower some of the other parts, but actually squeeze them up and encumber the façade unnecessarily and unmeaningly. It further strikes us as singular that Mr. Cockerell should not have exhibited his model for the same building also, as, besides that it would have been a striking object in the room, and would have explained the whole design, we have heard it spoken of as abounding with many effective parts. Still even if he chose to withhold that, we think he might very well have permitted us to see the designs of some other buildings either in progress or about to be begun by him, for instance the New Libraries at Cambridge, the Sun Fire Office at the corner of Bartholomew Lane, and the Taylor and Randolph Institute, at Oxford. Not having chosen to do so, he has no right to be very much astonished should some persons draw unfavourable inferences from it, and impute it to something like a consciousness on his part that none of those designs are calculated to raise his professional reputation.

Like Cockerell, Mr. Barry exhibits only one design, yet that one is altogether new as to subject, and of considerable importance. We were aware that Mr. B. had been commissioned by Lord Francis Egerton to prepare a design for Bridgewater House, but hardly expected to be gratified with sight of it so early. With regard to the subject itself, it will not detract from his high reputation; at the same time we question whether it will add to, or we should say, will raise it very much, since an edifice of such a character and upon such a scale must of course extend its author's celebrity. Grandeur and stateliness it certainly possesses;—and that is something, or rather a very great deal, considering how very rarely we obtain those qualities or any thing like them in structures where we might reasonably expect to find them, and from which they certainly have not been excluded by severe economy,—for instance, the unfortunate and deplorable *à la* Regent Street Buckingham Palace. Bridgewater House is noble and princely in aspect, which is what cannot possibly be affirmed of those two ducal mansions, Stafford House, and Wellington or Apsley

House, which last is so remarkable for nothing as for its smugness and spruceness, for its utter want of dignity, and downright insignificance of manner. Still though there is a fine architectural feeling pervading the whole of Mr. Barry's design, we cannot say that it is marked by originality, notwithstanding that a mansion of such a character will in itself be quite a novelty in the metropolis. It will be a large, oblong and insulated pile of building, two sides of which are shown in the drawing (No. 981), viz., the South and West, the latter facing the Green Park. Judging from what we see, we presume that the same architectural character will be kept up throughout the whole of the exterior, and that the North side will be the principal entrance front, there being there a square tower carried up a story higher than the rest of the edifice, from which we conjecture that the lower part of it will form a carriage porch. The summit of this tower shows itself picturesquely in the view above the general mass of the mansion, and is, no doubt, intended to serve as a sort of belvedere,—an appendage certainly uncommon, but in this instance justified by the locality, in the immediate vicinity of the Parks. We may describe the design generally—at least what is here shown of it, by saying that it consists of a rusticated basement or ground floor, with a continuous Corinthian order, comprising a principal floor and mezzanine; the whole surmounted by a balustrade and vases of globular form. Both the elevations which are shown are perfectly similar in design, except that the South front, which has fifteen intercolumns, consequently so many windows on each floor, has pilasters, while the West front or end towards the park, has three-quarter columns, and six intercolumns less, or only nine windows on a floor. In both elevations, all the windows of the principal floor have triangular pediments, and the mezzanine ones keystones to their architraves. The angles of the building are strengthened by coupled pilasters, so that two adjoining ones exhibit a group of three of them. It should further be remarked that the superstructure is in some degree rusticated as well as the basement, the jointings of the stone being shown on the surface of the walls between the columns, &c. This must suffice in the way of description,—which however exact, can merely enumerate the several items of a design, without exhibiting their aggregate effect; and the particulars we have noticed will serve as an outline of this composition of Mr. Barry's. The size of the building may be tolerably well guessed at, for the Park front may be taken as very nearly the same as that of the Reform Club-house, each having nine windows in breadth, and the proportions of the openings and spaces between them appearing nearly the same in each case. At any rate the difference cannot be much either way, consequently the South front of Bridgewater House, will be to that of the Reform Club as 15 to 9; or we may compute its extent at 190 feet, more or less.

It will be said—we have, in fact, said as much already ourselves, that there is nothing very striking either in the individual portions of this design, or in their combination:—it is nothing more than an excellent application of a good Italian style—absolutely nothing more. But then there is this difference, and a most prodigious one it is, between Mr. Barry's imitations and those of many others—see for instance a lately built façade in Regent Street,—that he generally refines and ennobles the style, and gives us its true sentiment, while they, more frequently than not, absolutely vulgarize it, and render it poor and insipid. If Mr. Barry's principle of composition is no secret to them, why do they abstain from making use of it themselves? It is true, not every one has the same opportunities afforded him, but even those who have favourable opportunities do not turn them to the best account—often throw them quite away, giving us the crassest architectural crudities. We own that Barry has here had a most noble opportunity put in his way; and should the design be strictly followed out—at any rate not impaired by being *pared* down, we may safely predict that it will prove a splendid addition to our metropolitan architecture; and we further trust will be an example forming an epoch in it, by stimulating others of the nobility to imitate such precedent;—whereas hitherto there has been some sort of excuse for their choosing to keep their houses as plain and as homespun in appearance as possible, lest while seeking gala suits for them, they should be imposed upon by such rascally Monmouth-street finery as that in which the Regent Park terraces, and other similar accumulations of architectural Brummagen, tawdriness and vulgarity, are bedizened out, till they almost look like so many regiments of ginshops.

We must pull up and rein in our Pegasus, for we are now got we know not where,—among Charles Barry's antipodes,—the ultra-cockneyfications of people who build by wholesale,—how unlucky that they do not also build for exportation only!—Quiet! Pegasus, quiet! dont kick. We notice some monstrosities of the kind on the walls of the Academy—as when do we not. Nevertheless we will not notice them further at present; therefore give them a chance of escape.

Instead of proceeding methodically, according to the order of the catalogue, we plunge *in medias res*, and turn to No. 1006, Mr. H. L. Elmes' Design for St. George's Hall, Liverpool, which certainly satisfies us much better than did any of the drawings for the same subject, exhibited last year. To say the truth, it is much superior to the general run of our Anglo-Grecian architecture, in which there is nothing Grecian except the columns alone, while here there is some taste, and some study shown as to the other parts. The solid, but ornamental stylobate, enriched with a narrow panel with figures in relief, is good and effective, and some play is produced by the entrances being made separate compositions at the extremity of this stylobate; but we do not understand why instead of being continued throughout, the panel should be divided into two by a blank space forming a break in the centre of the stylobate. The order is a fluted Ionic, forming an advanced colonnade of thirteen intercolumns, containing as many windows, which besides exhibiting considerable novelty as to the pattern of their glazing, are more than usually decorated, and have cornices of peculiar design, crowned by a central ornament—a novelty that deserves to be encouraged, though the form itself might be improved upon. The cornice of the order is also better, because less meagre and insipid than usual, and possessing some degree of embellishment. Thus far we can conscientiously commend—and though it may stand for nothing, our commendation means something; but we must also qualify our praise by some objections, one of which is that the colonnade appears so shallow, as to be little more than an ornamental range of columns placed before the building, nor does there seem to be any entrance to it from the interior. Neither do we at all approve of a colonnade of this kind being made prostyle or jutting out from the building, as if it were a portico forming the approach to it; because it looks too much like a mere useless addition to it, nor is that effect of shadow obtained which is produced by recessing the space behind the columns within the building. However from a perspective elevation alone it is impossible for us to judge very accurately in regard to such circumstances. His other design, for the Law Courts, turns out much better than we expected, for when we first heard that its chief feature was a Grecian Doric portico, we were apprehensive that it would prove merely one of those ultra-Grecian affairs concocted according to recipe à la Stuart, in short some such *regularly* classical piece of design as the New Liverpool Custom-house. We were therefore agreeably surprised at finding it so very much better, and with more than usual taste as to composition, and study as to detail, in which last respect there is one rather happy novelty in the mode—not easy to be plainly described—in which the podium and its mouldings follows the curve of the columns, and form what may be considered either continuations of their shafts, or distinct pedestals, by the podium itself being omitted in the intercolumns beneath the pediment. The general design may be described as consisting of five compartments, viz., a narrow one at each end between antæ, and three others making altogether seventeen open intercolumns, five of which form the slightly advanced central division beneath the pediment; consequently the arrangement of the whole façade bears so far considerable resemblance to that of the Fitzwilliam Museum, at Cambridge. The whole is raised on a low stylobate, and the ascent to the portico is tastefully managed. The pediment is filled with bas-relief.*

Good as the preceding design is, there is far more of originality, both as to conception and treatment, in No. 998, (E. B. Lamb,) for the same building, described in the catalogue as being in an Italo-Grecian style, to which designation it answers sufficiently correctly, being for the most part Grecian in its physiognomy,—in the regularity and richness of its columniation,—but relieved from Grecian monotony by some judicious modifications, and by some application of Italian features. Leaving others to settle whether such style would best be turned Grecian *Italianized*, or Italian *Grecianized*, we will examine the merits of the design itself. The order which is Ionic, is raised upon a somewhat lofty stylobate, or rather, basement floor, and is carried uninterruptedly throughout the whole façade, so as to form an open colonnade of 15 intercolumns, and a closed compartment at each extremity between bold coupled antæ. This last circumstance gives additional value to the rest,—for those parts contribute materially to breadth and repose, while they are far more important in themselves than had there been merely two antæ and the space of an intercolumn between them. At the same time that greater contrast is thus obtained, a pleasing degree of uniformity has also been kept up, and this has been accomplished in a manner as effective and tasteful as it is novel, viz., by recessing the upper part of the wall between the antæ, so

* We have been informed that this design is almost identically the same with that by Barry for the Law Courts, proposed to be erected in Lincoln's Inn Fields. We greatly doubt, however, if such be the case, except, as far as the general arrangement goes; for if the peculiarity above pointed out, with regard to the columns, be the same in both instances, it would be a very remarkable coincidence indeed.

as to admit of a large statue being there placed at each end, and which of course becomes strongly relieved by the mass of shadow surrounding it. This may so far not be Grecian, because there is no direct authority for it, but then it is on that account all the more meritorious, because it is most certainly, both Grecian and classical, in sentiment. Similar in character to the parts just described, but with some variations, owing to their being more extended, are the elevations of the ends of the building, so that the whole is in keeping throughout; which we are sorry to observe is a much greater and rarer merit than it ought to be,—certainly one that has been utterly disregarded by the classical architect of the Post Office. Among other points that particularly recommend this design of Mr. L.'s, is that he has kept up or rather enhanced the dignity of the colonnade, in the first place by introducing inner columns in the part serving as a vestibule between the two courts, and in the next by avoiding windows, and making the two doors seen behind the columns very conspicuous and highly ornamental features. There is also much that is equally good and new in the details of the order itself,—in the capitals especially, and likewise in the cornice.

(To be continued.)

ENGINEERING WORKS OF THE ANCIENTS, No. 5.

THUCYDIDES, who wrote about the year 400 B.C., is the next whom we shall take in our discursive course; his history however presents few gleanings.

WALLS OF ATHENS.

About 481 B.C., the Athenians restored their dismantled walls, and also enclosed the Piræus.* From political circumstances the works were very much hurried, the foundations were laid with stones of all sorts and sizes, some unwrought, and just as they were brought up by the servers. Many pillars too from sepulchral monuments, and other wrought stones were worked up in the building; for the boundary wall of the city was now far greater, being in every direction carried out; and for this reason it was that they urged on the work, employing alike whatever came to hand. It was Themistocles, too, who persuaded them to build the remaining walls of the Piræus (for this had been begun by him during the year of the archonship which he filled at Athens), thinking the place highly favourable, as having three natural ports, and that as they had become a nautical people, it would much contribute to their obtaining naval power. Indeed he first ventured to tell them they should apply to the sea, and then immediately assisted them in acquiring the empire of it. By his counsel it was that they built the wall of that thickness about Piræus; for two wains brought stone, passing by each other upon it, and going contrary ways. Within, there was neither rubble nor clay, but the stones were large and hewn square, fitted together in building; and those on the outside bound together with stone and lead. The height however was only finished to about the half what was designed, for his intention was to effectually repel all hostile attacks, both by the thickness and the loftiness of the walls, and he thought that thus a few, and those the least effective persons, would be sufficient to man it, and that the rest might embark on board the fleet: for he chiefly devoted his attention to the shipping, perceiving, it seems, that there was a readier access for the king's (Persia's) forces against them by sea than by land. For he judged that the Piræus would be more serviceable than the upper city, and often counselled the Athenians that if ever they should be foiled by land, they should descend thereto, and with the navy make head against all opponents.

Frequent mention is made in other places of walls of defence and offence, but these do not present sufficient general interest to call for particular notice.

The Athenians, as we shall hereafter have occasion to mention were distinguished as engineers, and particularly skilful in constructions of this kind. On account of the peculiar mode of building, workmen were employed who were skilled in this iron cramping.† Thus we find that to the seige of Nisæa were sent iron and stone-masons.

MINES.

Although Thucydides was himself a proprietor of mines, we find very few and short notices in his work. In the First Book chapter 100, allusion is made to a mine in Thrace, of which mention is made by no other author. In the Second Book, chapter 55, our author recounts that the Peloponnesians, having devastated the champaign country of Athens, passed into what is called the territory of Paralus, as far as Laurium, where were the Athenian silver mines, to which however they appear to have done no injury. The gold mines near Thrace were possessed by Thucydides,* and are supposed by the commentators to have been situated at Mount Pangæus, and to have been the same from which Philip, King of Macedon, derived the funds which enabled him to conquer Greece.

ATHENIAN ENGINEERS.

The reputation of the Athenians as engineers is attested by Thucydides in the following passage.† The Lacedemonians as their war against the rebels in Ithome ran out into a length of time, demanded the assistance of the allies, and amongst others of the Athenians. No small number of these were sent to their aid under the command of Cymon. The demand of assistance from them was principally owing to the reputation they then were in for their superior skill in the methods of approaching and attacking walls.

VALUE OF WROUGHT MATERIALS.

Another of those circumstances which attest the value of manual labour among the Greeks, we find in the Second Book, in the account of the preparations made by the Athenians for sustaining a siege during the Peloponnesian war, when they removed into the city not only their moveable property, but even much of the woodwork of their houses.

CONDUIT AT ATHENS.

Thucydides (Book Second), mentions at Athens a conduit called the Enneakrounos or Kine Pipe, from the manner in which it was embellished by the tyrants, formerly called Callirhoe.

SIEGES.

The sieges described in this history do not well come within our sphere, but those who are desirous of ascertaining the resources of Greek military engineering, will do well to refer to them, particularly to the siege of Platea. Here we find mining, countermining, raising mounds, walls of circumvallation, &c.

BRIDGE OVER THE STRYMON.

In the Eighth Book we find the bridge over the Strymon, mentioned by other authors referred to.

PERSIANS.

DIVERTING RIVERS.

We find in Thucydides one solitary mention of the Persians, and that with regard to the art in which they excelled, hydraulic engineering. Megabyzus, the son of Zepyrus, commanding the Persian forces in Egypt, having driven the Greeks out of Memphis, drove them into the isle of Prosopis, where he shut them up. Here he kept them blocked up for a year and six months; till having drained the channel, by turning the water into a different course; he stranded all their ships, and rendered the island almost continent. He then marched his troops across, and took the place by a land assault.

Diodorus the Sicilian, was the author of a general history called the Historical Library; he flourished in the first century before the Christian era. The first of our gleanings from the translation of his work by Booth, relates to the Egyptians, who are treated of in the First Book.

EGYPTIANS.

HONOURS PAID TO ENGINEERING.

All writers in Egypt attest the honour in which the Egyptians held the construction of public works, many of their oldest monuments being attributed to the gods. The god Osiris, by some is named as the founder of Thebes, and he made an expedition through the world for the purpose of introducing civilization, during which he built several stately cities, particularly in Ethiopia and India. In enumerating the merits of the kings, our author says, "And besides all this, were conquerors of many nations, and grew exceeding rich, and their provinces were beautified with many stately magnificent works, and their cities adorned with many rich gifts of all sorts."

EMBANKMENT OF THE NILE.—HERCULES AND OSIRIS ENGINEERS.

In the time of Osiris, the Nile is reported to have broken its banks, and overflowed the greater part of Egypt. On this occasion the old or Egyptian Hercules, who, says our author, was always for old and difficult enterprises, and ever of a stout spirit, presently made up the breaches, turned the river into its channel, and kept it within its ancient banks; and therefore some of the Greek poets, from this fact, forged a fable, that Hercules killed the eagle that fed upon the heart of

* Book 1. ch. 93. † Book 4. ch. 69.

* Book 4. ch 106. † Book 1. ch. 11.

Prometheus. The most ancient name of the river was Oceames, which in the Greek pronunciation was Oceanus, afterwards called Eagle, upon the violent eruption which covered a great part of the province governed by Prometheus, in consequence of which he died of grief.

What Hercules did for the lower part of the Nile, Osiris did for the upper part of the same river, for having come to the borders of Ethiopia, he raised high banks on either side of the river, lest in the time of its inundation it should overflow the country more than was convenient, and make it marsh and boggy; and made floodgates to let in the water by degrees as was necessary.

Uchoreus, whom Diodorus calls the builder of Memphis, thus managed the site he had chosen. The Nile flowing round the city, and at the time of the inundation covering all round on the south side, he cast up a mighty rampart of earth, both for a defence to the city against the raging of the river, and as a bulwark against an enemy by land; on every side likewise he dug a broad and deep trench, which received the violent surges of the river, and filled every place round the rampart with water, which fortified the city to admiration.

We here find Osiris, the chief god of the Egyptians, and Hercules enrolled among the patrons of engineering, so that when the profession is driven to a pinch for an emblem, here is the *deus ex machina*. Hercules destroying the eagle preying on the vitals of Prometheus, will make a pretty device either on a medal or on a service of plate presented to a member of the profession.

EMBANKMENTS OF SESOSTRIS.

Sesostris on his return from his warlike expeditions applied himself like his predecessors to the adornment of his country. Among his other labours are mentioned that he raised many mounds and banks of earth, to which he removed all the cities that lay low and in the plain.

CANAL OF THE RED SEA.

The following is the account which our author gives of the famous canal of the Red Sea. From Pelusiacum as far as to the Arabian Gulf, and the Red Sea is a canal cut out. Necos, the son of Psameticus, was the first who began this work, and after him Darius the Persian carried it on, but left it unfinished, being told by some that if he cut it through the isthmus all Egypt would be drowned, for that the Red Sea lay higher than Egypt. The last attempt was made by Ptolemy the Second, who cut a sluice across the isthmus in a more convenient place, which he opened, when he had a mind to sail down that way, and then presently after shut up again; which contrivance proved very useful and serviceable. The river which runs through this cut is called Ptolemy, after the name of its maker. Where it falls into the sea, there is a city built called Arsinoe.

According to Diodorus, Nile, King of Egypt, called the river after his own name. For being that he cut many canals and dikes in convenient places, and used his utmost endeavour to make the river more useful and serviceable, it was therefore called Nile.

Sesostris also cut a great many deep dykes, or canals from the river, all along as far from Memphis to the sea, for the ready and quick conveying of corn and other provision and merchandise, by short cuts thither, for the support of trade and commerce, and maintenance of peace and plenty all over the country. These canals served also as defences.

COCHLIA.

Our authors say that the land was watered from the canals by means of a certain engine, invented by Archimedes the Syracusan, and which received its name from its resemblance to a snail's shell.

LAKE OF MERIS AND THE LABYRINTH.

So much distrust has been thrown on the account of the Lake of Meris, that we think it better to refer those of our readers, who are desirous of obtaining information respecting it to the original, rather than give it here.—The same remark we must make with regard to the Labyrinth.

WALL OF SESOSTRIS.

Sesostris is recorded as having built a wall for the defence of the east side of Egypt, against the irruptions of the Syrians and Arabians. This wall is stated to have extended from Pelusium through the deserts as far as Heliopolis, and to have been fifteen hundred furlongs, or about two hundred miles in length.

PYRAMIDS.

The Pyramids and Obelisks are works certainly belonging to engineering, but as it is our object rather to show the bearing which ancient history has upon the practice of the art in modern times, than to elucidate subjects, which more properly belong to the province of the antiquarian, we content ourselves with reminding our readers, that in the author before us they will find much information with regard to these splendid works of art.

GEOMETRY.

The priests were the instructors of youth, and the learning taught by them was called sacred. In arithmetic and geometry, even in the time of our author, they kept the students a long time.

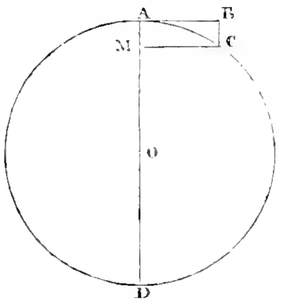
(To be continued.)

ON THE ACTION OF CENTRAL FORCES.

"Happy is the man who can discover the causes of things."

Sir—In the number for April last, there is inserted a paper on central forces, in which the writer endeavours to prove the existence of "an inscrutable law of nature," according to which centrifugal force is excited by the curvilinear motion of a heavy body.

Before offering remarks on that paper, let us first inquire into the distinct action of the forces that retain a heavy body in a circular path.



Taking the usual diagram, let A C D be a circle of revolution, A C any very small part of it, A O D the diameter at the point A, and B M the rectangle on the diagonal A C. Then A M is the effect of central attraction on the body at A, and A B its projectile motion. The motion in A M is accelerative, being originated from nothing by central pressure. The motion in A B is uniform, being the result of an impetus previously communicated. Now the ratio of A M to A B may be diminished to any extent, by diminishing A C. For $AB^2 = AM . MD$, and therefore $AB : MD :: AM : AB$. Now, in reducing A C we reduce A B also, and the less we make A B, the less is its ratio to M D or A D, and the less also is the ratio of A M to A B; and this ratio may thus be diminished to any extent. Thus, also, the circular motion may be considered ultimately, when A B becomes indefinitely small, to be composed of projectile motion and incessant central pressure. Again, $AC^2 = AD . AM$, and $AB^2 = DM . AM$, therefore $AC^2 - AB^2 = AM . (AD - DM) = AM^2$. But it appears that this difference may ultimately be neglected; therefore $AB = AC$ ultimately. But A C will be the momentary projectile motion of the body when arrived at C, and therefore, as the other circumstances of motion are the same as at point A the new resultant and consequently, also the new projectile motion $= AC = AB$. This proof holds good at every other point, and therefore the motion in the circle must be uniform, and equal to the original projectile motion.

To proceed; the writer begins with a familiar example of rotatory motion in the operation of electro-magnetic attraction upon a projected bar of iron. He says that its motion in the circle is uniform, because the deflecting and projectile forces do not influence one another, being independent of each other, and acting at right angles. Now, certainly they are independent as to origin, for the bar would adhere to the magnet, though it moved not at all. But the deflecting force is dependent in respect of *quantity* upon the other. We cannot certainly say that the whole power of attraction is deflecting force, though the writer says so expressly in another part of his paper, page 115. On this supposition we might make the deflecting force as strong as we please, other circumstances being identical; which is absurd, and would, if true, overturn entirely our mathematical demonstrations on the subject, including propositions of which he himself makes use. In fact, magnetic attraction may be much greater than is necessary for that purpose. The deflecting force, then, strictly so called, is just so much of the attractive force as is necessary for deflection, the overplus being superfluous pressure. Respecting their action at right angles, I have already shown, that the deflecting force greatly influences the projectile. In fact it perpetually combines with it, and produces resultants equal to one another, and to the projectile motion. *This* is the reason of the constancy of circular motion.*

Mystifying the origin of centrifugal force, he says that as it is equal and opposite to the centripetal force, it cannot arise from the magnetic

* He says again, the centrifugal force cannot be the resultant of the other two forces, for it would then point within the circle. This contradicts the very definition of circular motion, which is that the resultant is neither within nor without, but *in* the circle.

action. Certainly not from the overplus action, but undoubtedly from the deflecting magnetic action, for it is evidently just a case of the third law of motion; that action and reaction are equal and contrary: a very satisfactory explanation, yet what an effort is made to obscure the subject!*

The writer now drives the apparatus with a winch, and supposes the magnetic attraction to perform the business of cohesion, and then asks if his hand imparts the centrifugal force. This requires no answer from me, and he has thought fit not to do so either.

His illustration in the case of a sling, I confess I understand not. It involves the absurdity of expressing velocity in terms of weight; although, as I understand it, it ought to be told in terms of space and time.

The instance of the fly-wheel has little new, except the manifestation of another misconception of the writer's. "The central (centrifugal) force, says he, acts by pressure, and a resultant from that pressure and the force in the circle is the consequence, but so long as resistance from cohesion continues, neither motion nor pressure can be imparted to another body by the central force." The writer here exchanges cause and effect, for he would fain attribute a self-exciting property to the centrifugal force, and insinuates accordingly that the resistance of cohesion is the *consequent* centripetal force. Whereas the reverse is the case; the cohesion is exerted, because it perpetually winds the direction of projectile motion; and the centrifugal force is plainly the *inertitic* (forgive the innovation) tendency of the body to rectilinear motion. There is also something said of moment of rotation, irrelevant to the subject.

The experiment of the whirling table simply confirms what was proved long ago, that, using the writer's symbols, $x = \frac{v^2}{r}$.

After recapitulation, he concludes the first part of the subject with the notable inference, that centrifugal force is a physical agent, excited by an inscrutable law of nature when matter moves curvilinearly. I need not say how unnecessarily this law has been brought forward. It really would be more surprising than the formation of magnets by electric operations. For electricity and magnetism are identical, and therefore naturally enough such a result should take place. Though we may not know the absolute nature of physical principles, we may accurately know their relative nature. Therefore the writer is unfortunate in his allusion, as we are dealing in relatives, not in absolutes.

Proceed we to the second part of the subject: the composition of the projectile and centrifugal forces. And here an absurdity at once presents itself. We are told that a ball weighing 1 lb. moving in a circle of 2 feet radius, at the rate of two revolutions per second, has a projectile velocity of 25·14 per second, and a centrifugal velocity of 157·76 per second. This number has evidently been the result of the formula $\frac{v^2}{2r}$, which expresses the proposition quoted from Brewster's Encyclopedia. For $\frac{25 \cdot 14^2}{4} = 157 \cdot 76$ feet. Now, it is a misnomer to call this the velocity per second. It is the space passed through in a second by the body, with a motion accelerated from nothing. We might as well say that $\frac{157 \cdot 76}{2} = 78 \cdot 88$ feet would be the space passed through per half second. But what would the rule give us? The projectile velocity per half second being 12·57, we would have by the rule $\frac{v^2}{2r} = \frac{12 \cdot 57^2}{4} = 39 \cdot 44$ feet per half second: ludicrously inconsistent. The writer places the two forces on the same footing, whereas the one is impulse, the other pressure; which renders the succeeding reasoning a baseless fabric. I have shown at the commencement of this paper, which I fear is too long, that the shorter the time supposed for action, the less is the ratio of the effects of the projectile and centripetal forces, and therefore in any moment of time, the effect of the latter is unassignably less than that of the former. If he will turn also to Cavallo, whom he has so often quoted, he will find the same conclusion come to in his third proposition on curvilinear motion.

The experiment with the tube and balls, though it has the appearance of accuracy, is undoubtedly pointless. The apparatus must have been exceedingly clumsy to require "very high increasing velocities" to manifest the action of this wonderful power.

"As to the probable results of a practical application of this principle," they will be exactly nothing at all, as the experiment with the tube and balls well nigh proves.

I am, Sir, your obedient servant,

DANIEL CLARK.

Phœnix Iron Works,
Glasgow, May 10, 1841.

* The idea of the perpendicularity of their directions preventing their mutual action is very absurd. What is parabolic motion?

ON THE EMPLOYMENT OF MILITARY ENGINEERS.

SIR—In your last month's Journal, under the above head, I find an attack made on military engineers and military engineering, as uncalled for and unprovoked, as it is narrow-minded, illiberal, and ungentlemanly, and I am sure that from a sense of justice you will insert these few remarks in reply to the anonymous libeller who signs himself "Civilian."

The purport of the writer is an evident desire of venting his petty spleen on a body of talented, high-minded, and honourable men, and whilst I much regret that your columns have been made use of for the purpose of libelling a "Captain of engineers at the head of the architectural and engineering departments of the Admiralty," viz. Captain Brandreth—a gentleman whose talents, urbanity and kindness have endeared him and made him respected by all who have been connected with him in his professional capacity—I am sure that no civil engineer laying the slightest claim to station, to gentlemanly feeling, or to respectability, would ever descend to such low personalities, nor will "Civilian" ever obtain the sanction or countenance of such men to his vituperations.

If "Civilian" had the benefit and the interest of the civil engineer at heart, he would never for a moment wish to weaken the union which is now daily increasing between the civil and the military engineer, for their mutual as well as for the public good. The spheres of action of the two professions lie in almost every case so widely apart that they may be said never to clash; while the foreign services of the military engineer open to him a vast field of inquiry and information, which those who practice in this country as civilians are unable to obtain. His varied information, his experience, strength of mind, and coolness for calculation, fully entitle him to such offices as the country is able to give; and in *justly* awarding the few she does to him, she but acts for her own interest.

With respect to young gentlemen who are educated at the military colleges—is "Civilian" aware of the rigid examination these gentlemen have to pass through before they are entered into the corps of engineers? and that but a very small number are admitted into *that* corps every year? Is he also aware of the number of young gentlemen who are annually sent out of engineers' offices, after spending, as "Civilian" boasts, "nearly £1000," is he aware that *they* are sent out without *any examination*, and in most cases with a meagre knowledge picked up in the best way they are able, and not "drilled under the auspices of their colonel"—would they had been! And why, I would ask, are men of talent, of exertion, of experience, not to practice in the varied callings of their profession, if they so please, if they are competent, and if the public will employ them?

I am a civil engineer myself, which fact I doubt of "Civilian," indeed I would not, for the credit and the respectability of the profession, believe he ranked himself as one, as no man holding any station in it, much less having any respect for himself, would be the author of such a production.

I am, Sir,
Your obedient servant,

Bristol. VERITAS.

SLATE CHIMNIES.

SIR—Having lately adopted a plan, by means of which slate slabs may be made use of, in the construction of chimneys or flues, in connexion with an open fire grate, and in situations where the common brick chimneys could not be built, I take the liberty of submitting the plan to your consideration.

Having not long ago taken possession of a house, attached to which was a room built at the side, and not having fire place and chimney I adopted the following plan:—I fixed to one of the walls of the room, at a proper height from the floor, a common open fire-basket or grate, having a strong iron back, not let into the wall, but fixed in front of it. I then had four long narrow slate slabs put together, so as to form a square hollow pillar open at top and bottom, and the pillar so formed I had erected against the wall immediately over the fire-grate, and carried the pillar out through the ceiling and roof of the room. The fire-grate and flue thus enclosed, had a chimney-piece of slate set to correspond. The slate, not being so good a conductor of heat as iron, does not give out any thing like the same quantity of heat an iron pillar or pipe would have done; at the same time the heated air, passing up through the slate pillar imparts to it such a degree of heat, as adds very perceptibly, and I may add very pleasantly, to the warmth of the room. The Welch slate, as is well known, will crack* on being exposed to a very slight degree of heat, but my slabs were made of Valencia slate (from quarries in Ireland), which do stand heat very well, if cautiously applied in the first instance.

The superficial quantity of slate used was very small, the slabs being very narrow, consequently the expense was very trifling. The economy of heat I consider to be no small advantage in my plan. In the case of a common brick chimney let into the wall, the heated air passes up it, imparting no heat to the room, but in the case of this slate pillar, erected *within* the room, the heated air passing up through it, is conducted by means of the slate into the room. Indeed it was found that the warmth of the room was fully maintained with a very small consumption of fuel.

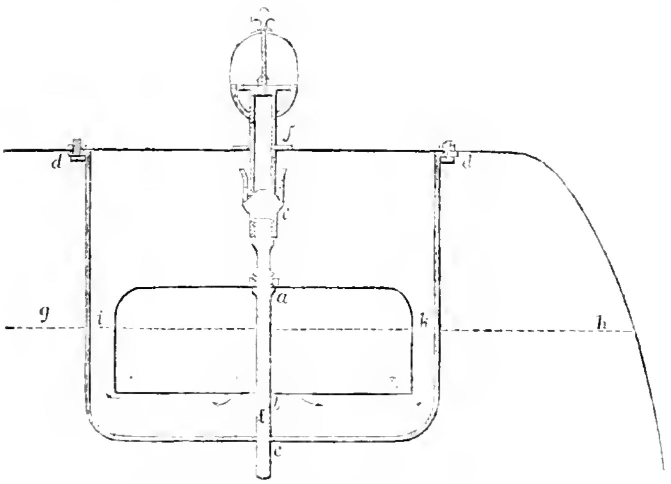
Should you deem this little plan worthy of being brought to the notice of your architectural friends through the medium of your valuable Journal, it will much oblige, Sir,

Your obedient humble servant,

London, May 6. A Lover of the Fireside.

ALARUM WHISTLE FOR STEAM BOILERS.

Sir—The enclosed sketch represents, in section, a simplified form of alarum whistle for steam boilers which has occurred to me. Should you deem it worthy of insertion, you will perhaps give it a place in your valuable pages.



a, i, k, b, is a float, which consists of an inverted vessel of sheet iron or other metal, through the centre of which passes a spindle *a c*, having a collar at *a*, upon which the float is screwed down by a nut outside. At the upper end *e* is fixed a cap of brass with a joint ground steam-tight to the bottom of the whistle *f*; *d c d* is a stay through which the spindle *a c* passes, having sufficient clearance in the hole at *c*. This stay may be either double, as shown, or single. At *b* is a cotter which prevents the spindle dropping farther than the distance from the bottom of the cotter to the stay at *c*; *g h* is the surface of the water.

When the steam is down, the cotter in the spindle rests upon the stay, through which the spindle passes leaving the passage at *e* open. As soon as the steam rises, the vessel *i a k b* fills with steam and rises to the position shown in the sketch. When the water falls the float also falls, leaving the passage to the whistle open, and is stopped in its descent, as above described, by the cotter *b* resting on the stay. There are holes at the sides of the cup *e* as well as a passage through the top to prevent the lodgment of dirt, &c.

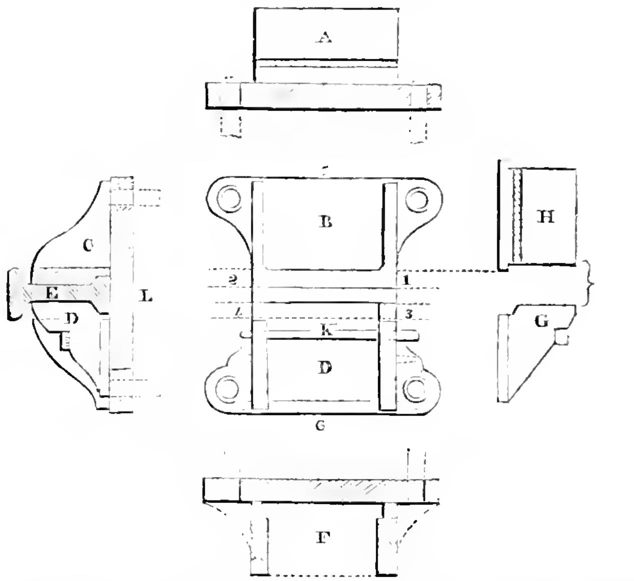
The advantage which I think this apparatus possesses above any I have yet seen, is the absence of any working joints, there being only two points of contact required, at *e* and *c*, and those leaving clearance. The whistle will also act as a vacuum valve when the steam goes down; for it is evident that when the steam is below the pressure of the atmosphere, it will be condensed in the float vessel, which will consequently fall by its own gravity.

I am, Sir,

Your's obediently,

Liverpool, May 15. G. J. Horner.

NORTH OF ENGLAND RAILWAY CHAIR.



A, section from 1 to 2.—B, plan of chair.—C, section from 5 to 6.—D, ditto, locking cheek in its place.—E, ditto, rail.—F, ditto, from 3 to 4.—G and H, side and end of locking cheek.—K, malleable iron key or wedge.—L, stone blocks, or wood sleepers.

Sir—I beg to hand you a sketch of a joint chair with some explanation, &c., and a section of the rail used on the Great North of England Railway, which are at your service. The chair is considered to be well adapted to the rail, and simple in its principle. The middle chair, as well as the cheek chairs, are on the same construction, but vary in the weight:

Joint chair	40 lb.
Middle do.	41
Cheek do.	30
Rail per yard lineal	60

The railway has now been opened since the beginning of last April, and keeps in a good working condition, there are very few slips or subsidence in any of the embankments or cuttings. From the easy gradients, solidity of execution, and other favourable features connected with the Great North of England Railway, it readily may be inferred that the line will be worked at less cost than any other line of the same extent.

I am, Sir,

Your obedient servant,

York, May 12. M. Q.

GREENWICH RAILWAY.

List of tenders of the third contract for widening the railway between the London terminus and the Croydon Junction, delivered in on the 27th April last.

Mr. Jackson	£11,608

NEW AND USEFUL INVENTIONS.—No. 4.

By Philotechnicos.

PIMLICO SLATE WORKS, UPPER BELGRAVE PLACE.

These works have been lately erected for the purpose of sawing, planing, moulding, and turning slate by machinery worked by steam power, for the manufacture of a great variety of useful and ornamental articles. The slabs are distinguished by their ebon-like appearance and freedom from green spots or stains. They are produced from the proprietor's own quarries in North Wales, where they have extensive machinery worked by water power, and from whence the slabs are forwarded, roughly planed: they are here finished in various ways; the roughly planed are used for paving, wine binns, cisterns, covering, and common purposes, the smoothly planed for sinks, mangers, and shelves for larders and dairies. The snaked or finely rubbed for bettermost purposes of the same description, chimney pieces, hearths, baths, skirting and sideboards, and when oiled have the appearance of black marble. The next and most beautiful state in which the slate slab is used is when japanned; by this process it is subjected to great heat, which leaves on its surface a permanent polish, and is used for decorative purposes as a general substitute for marble or scagliola, and a most excellent substitute it is, being of a hard close texture it bears a sharp arris and brilliant polish, and one of its greatest advantages is cheapness.

Chimney pieces are made to any design, and their manufacture at this establishment forms one of the most useful applications of slate for building purposes; the imitations of conglomerate marbles are matchless, and the correctness with which machinery performs its duty is strikingly exemplified in every part of the work. I sincerely hope this invention will induce architects to introduce marbled slate chimney pieces in every place where the common-looking Portland is now used, to which material it is so superior that there is no comparison with regard to appearance, and is but little more in cost.

Sideboards, tables, cheffoniers, and other articles of furniture are likewise manufactured with the japanned and marbled slate, in the panels of which are occasionally introduced beautifully executed paintings, similar in appearance to those on papier mâché. A billiard table has been constructed at this manufactory, the whole of which, frame, bed and legs, is of slate; the legs are massive, and show the capability of slate for purposes of support.

For culinary purposes slate is particularly applicable from its cleanliness, the closeness of its texture preventing the possibility of imbibing any thing offensive, and requires only to be occasionally cleaned with soap and flannel to remove any impurities; it is consequently well adapted for sinks, shelves for larders, meat safes, and dairies, paste or butter slabs, salting vats, and many other purposes where a cool and clean material is required.

In the laundry it is useful for ironing tables, clothes presses, and mangles, the smooth and hard surface of the slate rendering the clothes subjected to its pressure nearly equal in appearance to their having been calendered.

Shops may be elegantly ornamented with slate, both internally and externally. In the shop front a brilliant effect might be produced by its introduction, with the advantage over marble of its retaining the polish after exposure to the weather; for counter tops and fronts and show tables a novel and pleasing effect may be produced, particularly in confectioners' and chemists' shops, taverns, railway refreshment rooms, and other places of public resort.

Stables fitted up with slate will have the advantage of superior cleanliness to any other material, its non-absorbent qualities preventing infection, and its hardness being an antidote to crib biting; the mangers, stalls, linings, and capping can be made of slate, as well as the corn-binn, which latter, being made with a sliding cover, and wholly composed of slate, is most useful, as being cool, cleanly, and proof against vermin.

Fire-proof buildings may be constructed with the greatest facility by the introduction of slate for the floors, skirtings, stairs, doors, and window frames. The drying-rooms, or, as they may be almost termed, the ovens, at this establishment, are composed principally of slate; the floors, shelves, and sliding folding doors, running with rollers upon a railway, and roof, are of slate, and subjected to a high degree of temperature.

I must confess my surprise at often seeing buildings erected for the purpose of warehousing inflammable or other goods with timbered and boarded floors; it is an unpardonable oversight not to take advantage of the various kind of materials suitable to this purpose, adapting the material to its use, and the many calamitous fires that have lately occurred, prove too truly the want of this discrimination. I do not know any thing better than slate to serve this end; light iron joists covered with slate slabs will form an excellent floor or flat, sliding doors can be constructed on rollers, and the stairs made entirely of slate—here then will be a building perfectly fire-proof at but comparatively small cost, and yet how little slate is used for this purpose. I am most anxious to draw the attention of architects and engineers to this particular point, as it is one of their imperative duties, as far as it is compatible, to render any portion of the building they can, fire-proof, substituting slate for wood in every case where such can be done with advantage.

Balcony bottoms, steps, and such works as require lightness and strength, can be constructed of slate, as it is calculated to be five times stronger than stone, and is, when only self-faced, comparatively smooth, or can be moulded and rendered perfectly smooth by machinery where a high finish is required.

Having enumerated several of the many uses to which slate is applicable, I shall conclude with a strong recommendation to the profession to encourage its manufacture as a material entirely of home production, and one capable of much diversity.

[We have received the following communication, showing the strength of the above slate.—Editor.]

Sir—The following trial of the strength of slate in its capacity to resist pressure, may not be altogether uninteresting.

Having occasion to cover a subway of considerable length under a carriage road, and being desirous to use slate on account of its non-porosity, it became necessary to test its strength, and I procured a piece from the Pimlico slate-works about 5 ft. 6 in. long, 5½ in. wide, and nearly 2¼ in. thick, planed fair on both sides. Messrs. Bramah and Wool, of the Grosvenor Iron Works, kindly made the required experiment for me.

The ends of the slip of slate having been placed on supports 5 feet apart, it was loaded in a pyramidal form with ballast iron, the centre loading being about 3 ft. 6 in. high, and the sides from about one foot. When weighted with 1 ton 5 cwt. 3 qrs., the slip broke. I fancied that I could detect a very slight deflection when the last cwt. was added, but although I had a line stretched along the bottom edge of the slip, the deflection was hardly perceptible when it gave way.

Mr. Magnus, the proprietor of the works, thinks this hardly a fair test of what the slate would bear, its strength being much reduced by the planing, which intersects the natural laminæ of the slate.

Torrington Square, Your's, &c.,
May 19. Henry Robert Abraham.

BENEVOLENT INSTITUTION FOR MECHANICAL ENGINEERS.

We have long regretted in the great advance of the profession, that while it possesses so many excellent scientific institutions it possesses none of a benevolent character. We are well aware that attempts have been made to supply this want, and that the principal cause why such efforts have not succeeded is that the want of benevolent assistance has not been sufficiently felt. It would be a libel indeed on the profession to suppose that while its members are so liberal in encouraging the spread of science, and in educating successors and rivals to themselves, that they should from pecuniary motives be neglectful of the material interests of their fellows, that while providing for the mind they should be neglectful of the body. The cause and the only cause has been the one which we have assigned, but we think that it now becomes a matter of grave consideration, whether the same circumstances should still be allowed to have weight. We have reason to believe that as regards the higher branches of the profession, notwithstanding the hundred and fifty candidates the other day for the Chief Engineership of New Zealand, no serious pressure exists, but with the growth of the profession, and on its assuming a settled form we think it is incumbent on us to provide for the future. Further our pride is at stake, for our's is the only profession which is without institutions for the relief of its members, and while we have our universities, our colleges, and our institutes, we have no benevolent society. It may be a matter of gratification that we do not yet want it, but we must not be sure that this will long be the case, or that the *dura paupertas* will be long before it subjects us also to its harsh rule. It must also be borne in mind that if the higher branches do not imperatively require to unite for such a purpose on their own account, there are other classes connected with them the promotion of whose welfare is not less imperative. The workshops are crowded with hundreds of men, who although enjoying high wages, are too frequently from defective education, wasteful and improvident, and here we must pause for a minute to remind our friends of another duty, which they too often neglect—the education of his workmen is a duty, which the engineer thinks he has nothing to do with, he pays the man his wages, and there is an end of the matter, the master may go on in neglect, and the workman in vice, and few take the trouble to consider whether it really is of importance to them or no, whether the workman becomes an intelligent being or a besotted brute. Let those however who think so read the evidence of Mr. William Fairbairn, given last year before the Parliamentary Committee on the state of the working classes, and he will see that by following his worthy example that much is to be done that will bring its own reward. The educated workman may not become a more skilled mechanic, but he becomes a better servant, he knows his own interests better and those of his master, he is steadier, less given to combination and to strikes, and in the words of the Quaker cotton spinner, has a positive money superiority. The untaught man, however skilful, is too often the source of annoyance to himself and others, looking with ignorant jealousy on his employers, he is ever watchful against any fancied infringement of his rights, ready on any sudden turn to fall into the snare of combining to increase his wages, and however large these may be too often spending both his money and his time in sensual and debasing gratifications, without making any provision for the time when his strength and his youth no longer avail him. It is this latter circumstance which should direct our attention to do what we can for the improvement of the workman's understanding and his morals, and at the same time we should endeavour to retrieve the errors of the past by giving every assistance for the relief of the unfortunate. Urged by these motives many of the most eminent of the mechanical engineers have come to the determination of forming an institution for effecting the desired results by their own aid, and by the contributions of the workman, so that the operative will at last be enabled to make a provision for himself, his widow or his orphan. The workmen of Messrs. Maudslays have already held a meeting for this purpose. At the late anniversary of the Committee of Marine Engineers, it was proposed that some general measure should be adopted for extending the plan to all parties connected with mechanical engineering. A specific plan has not yet been adopted, but the following among others have given their sanction to the general principle, and have agreed to carry it out—Bryan Donkin, Esq., V.P., Inst. C.E., Messrs. Maudslay, Sons and Field, Messrs. Miller, Ravenhill and Co., Messrs. John Penn and Son, Messrs. John and Samuel Seaward, and Capel, Messrs. Fairbairn, Murray, and Hetherington, Messrs. John and Alfred Blyth, John Hague, Esq., James Simpson, Esq., and W. Simpson, Esq., &c. Under such auspices we trust that the proposed institution will be established, and as immediate steps are to be taken to carry it out, we anticipate soon to witness its beneficial effects. Having given this information to the profession, we shall make no application to them for support, as we are sure that they want no asking to use every exertion for so laudable a purpose. In the course of next month we hope the Society will be organized, and in the meanwhile we shall be happy to be the medium of any communications addressed to it through our office.

ARCHITECTURAL COMPETITION.

Brown v. Langshaw.

Sir—In consequence of the erroneous reports of this case in the Cambridge papers and elsewhere, and particularly the attack upon my professional character contained in a review in the last No. of "The Civil Engineer and Architect's Journal," it has become necessary in self-defence to publish a plain statement of the facts connected with the whole matter. Wrong conclusions ignorantly or designedly drawn from correct statements, may be safely left to the judgment and common sense of the public, but when injurious imputations and charges affecting one's reputation are founded on error or perversion, a man must set but little value on his character were he to suffer them to go forth uncontradicted and unrepelled. Such is my position, and I confess it is one in which I did not expect to be placed, through at least respectable organs, and after the acknowledgment openly made in court by his Lordship and the defendant's counsel, that my character was in no way impeached in the transaction. I will not occupy your valuable space, as I had intended, by specifically replying to the errors and falsehoods contained in the report given in your last month's Journal, but will at once proceed to sketch the principal facts of the case, in order that the public may see its merits and judge whether, instead of my having deceived and misled the committee, I have not been most harshly and unjustly treated throughout the matter, and greatly wronged by the incalculable result of the late action.

I forbear also expressly replying to the imputations and assertions founded upon the mis-statements to which I have alluded, as I consider it sufficient to disprove the premises on which they are based, and rely on that amends which those who have been led to circulate them will, as honourable men, I am sure, award me.

It was in February, 1837, that I received a letter from the Rev. George Langshaw (see letter A.) as chairman of the committee, inviting me to compete with Mr. Rickman, Mr. Poynter, Mr. Sharpe, and Mr. Walter of Cambridge, in furnishing plans for the intended new church there. Taking the cue from this letter, in which the defendant writes "we are anxious to accomplish something as worthy as possible of the example of former days, more especially as our church will stand in the middle of Cambridge, opposite Christ's College," and from his criticism, "I will candidly tell you that your new church at Stamford has pleased many here, though the *inside* has been thought not equal to the outside," I prepared a design in which the interior was rendered exceedingly rich and effective, and the exterior considerably more ornamental than the Stamford church.

The latter structure, built on a design somewhat similar, and so furnishing practical data to a considerable extent for my estimate was executed for £3,500. The amount of expenditure fixed upon for the Cambridge church was £4000 *and* £500 (the value of the materials of the old church), but towards the completion of my drawings I had some misgivings as to the possibility of executing the building for this amount, and upon making my estimate, these misgivings were confirmed.

In laying my drawings before the committee, therefore, I distinctly declined to undertake to carry the design into execution, as it then stood, for the £4,500, but explained that certain portions of the ornamental work could be omitted, without in the slightest degree affecting the integrity or general design of the buildings, so as to bring it within that sum. (See letter B.)*

What other course, let me ask, would any man, even of the most fastidious sense of honour and integrity, have had me pursue? the more especially when it was known that my drawings were not completed even until the day they were sent off to Cambridge.

In October following I received a letter from the defendant, informing me that my plans were preferred, and I shortly afterwards attended a meeting of the committee, and received instructions to make certain alterations in the ground and gallery plans, and to prepare two new perspective drawings of the exterior and interior denuded of the expensive ornamental work, and exhibiting the building in the state described in my letter.

The plans thus altered and those unaltered were then again submitted to the committee, and the whole were formally approved by receiving the defendant's signature.

At the preceding meeting, however, certain conditions had been drawn up by the committee in the shape of resolutions, the effect of which was that they might decline my plans altogether, if the tenders should exceed the amount of £4,500, and that in that event they should not be bound to make me any remuneration for my drawings and trouble, beyond what would be made to the unsuccessful competitors. To these conditions it was required that I should give my unqualified assent before my plans could be finally adopted; but to this I had strong objections, considering them, by their stringency, calculated to embarrass and prejudice me, but proposed to qualify the condition as to the rejection of my plans, by adding the words "if the excess of the tenders should not be sufficiently accounted for."

Whilst this was being debated, the committee instructed me to prepare drawings and estimates of transepts, school-room, crypt, &c., and make many other alterations.

I did so, and at last, upon being pressed for an assent to the conditions, and assured privately by the defendant that these terms were only imposed as a matter of business, and with no intention of taking any undue advantage of me, I was induced at last to give it. My plans were thereupon formally adopted, and I received instructions to prepare the working or contract drawings; this was in December, 1837. Bearing in mind the observations in Mr. Langshaw's first letter before alluded to, and moreover perceiving that on the part of the committee generally there was still an earnest desire to obtain a building of as ornate a character as possible, I was induced, in preparing the working drawings, to assimilate them very nearly to the more ornamental features of the original design, relying upon being able to obtain the consent of the committee to the condition that in case the tenders were in excess, I should then be allowed to reduce the working drawings of such ornamental work as would make them agree with the plans considered as adopted. The parish would thus have the *chance* of getting the church so built for the £4,500. I accordingly proceeded with and completed the working drawings pursuant to this

* We have not received this letter.—Editor.

arrangement, and not, it will be perceived, under the resolutions which embraced only the plans as adopted. I afterwards attended a meeting called for the express purpose of inspecting them, where they were *inspected, explained*, and *sanctioned*, so that there was here a formal assent given to them, and I was allowed to go for tenders upon them. For whose benefit was all this done? For my own it could not be; my commission would not have been increased, whilst it was likely my labour would be.

In November, 1838, four tenders were sent in. I wonder there were so many, considering the committee insisted, against my protest, and compelled me to advertize, that they "did not pledge themselves to accept the lowest tender," and that one of the members officiously informed several of the builders applying to inspect the working drawings, that "they need not tender unless they were prepared to build the church for £4,000," or to that effect. All the tenders were in excess, a probability which the very arrangement I made necessarily contemplated: and what then was the course this honourable committee adopted? Why this (one more notable for its brevity than its equity); the chairman called me before them, and read me a paper stating that the tenders were in excess, and that my plans were declined pursuant to the resolutions. Surprised at this laconic address and summary dismissal, after nearly two years' labour, with more than £200 out of pocket, and in the teeth of a special understanding, I appealed to the agreement, and offered to perform my undertaking; but the only answer vouchsafed me was, "we decline your plans," and this although I afterwards proferred to enter into a bond to find an unexceptionable builder to build the church for the £4,500. Thus I was shamefully shuffled off, and not even afforded the opportunity of making that adjustment between my plans and the tenders, for which I had expressly stipulated (although unfortunately not in *writing*). Had not this arrangement been previously sanctioned, I should not, of course, have ventured the plans for competition, except strictly in accordance with the resolutions.

This is my case, and although the law has enabled my opponents to triumph over me, yet I must contend that equity and justice are still on my side. How far the statements made in the article which has been chiefly instrumental in calling forth this, are consistent with truth, I must leave your readers to decide. I will but remark that my statement flatly contradicts almost every assertion advanced; 1st. that by which I am made to have professed myself "perfectly clear," that my design could be executed for £4,000 or even £4,500, sufficiently disproved by my first letter to the committee. 2ndly, the statements as to the proposed amount of expenditure, which was £4,500 instead of £4,000. 3rdly, the gratuitous assertion that the committee were "troubled with a prejudice," &c., when the fact was, that the "conditions" were imposed subsequently to the competition, and after my design had been preferred and accepted, notwithstanding the contents of the letter accompanying the drawings, by which I so fully explained how the matter stood. 4thly, as to the time I kept the action hanging over the heads of the committee, it was not "nearly *four* years," but only about *two*, and this through unavoidable circumstances. I will not swell a long letter with the detail of my offers to meet the committee, and enter into explanations of any possible misunderstanding, or to refer the matter to some disinterested party for arrangement, made first by myself and then through my attorneys, nor dwell upon the inference to be drawn of the committee's fearing to meet the truth, by their pertinacious refusal either to see or hear me, or listen in the slightest degree to any amicable proposition. It was thus, with the greatest reluctance and compelled by obstinate injustice, that I at last engaged in litigation; I must otherwise have quietly sat down under a gross injury, which neither suited my interest nor comported with my duty. Besides, in going to trial, I had a further object in view beyond gaining a verdict, and that was to bring as much of the merits of the case before the public as I could, in order that even had the jury found against me, the true cause of my dismissal might be clearly known, and the prejudice which that fact has produced be removed. But in this, also, I have been foiled by the judge's intention, who did not look beyond the resolutions, although the main points of all I have here stated were actually given in evidence; his lordship, as well as the defendant's counsel, nevertheless, doing me the justice in stating that my character was in no way impeached, even in their view of the case. My counsel's cross-examination of the defendant's witnesses, and right to comment on the whole case, and extricate it from the mystifications of my opponents, was thus stopt, the jury deprived of the power of giving *their* verdict, and my case prevented from having a trial. The only course left me was, therefore, to elect to be non-suited, reserving to myself the power of enforcing my right in such manner as may be most expedient.

Norwich, May 21. I am, Sir, your obedient servant,
John Brown.

Letter A.

To — Brown, Esq., Architect, Norwich.

St. John's College, Cambridge, February 22nd, 1837.

Sir—As vicar of the parish of St. Andrew the Great in this town, I am requested to inform you that it is the wish of the committee (appointed to carry into effect the re-building of the parish church) to adopt the method of a limited competition in the choice of an architect, and that the persons fixed upon are yourself, Mr. Rickman, Mr. Poynter, Mr. Sharpe (lately travelling Bachelor in the University), and Mr. Walter of Cambridge. We are anxious to accomplish something as worthy as possible of the example of former days, more especially as our church will stand in the middle of Cambridge, opposite to Christ's College. The sum we have raised is £3,300, we hope to realize £4,000 at least. I will candidly tell you that your new church at Stamford has pleased many here, though the inside has been thought not equal to the outside. Would you give us your opinion as to the probable expence of the like church at Cambridge—the freightage of stone I have heard put at £500 or £600. It is possible that something might be saved in our case by retaining and refacing the first story of the present tower, and the arches inside the church. But I shall be glad to supply you with any further particulars when assured of your readiness to send in a plan. I fear we cannot begin this year.

Your's, &c.,
(Signed) "Geo. Langshaw."

IMPROVEMENTS ON ECCENTRIC RODS.

Sir—I happened not to have seen any of your excellent numbers for this year till a few days ago; I see that there are several communications from Mr. Pearce, respecting an improved method of reversing engines with one fixed eccentric, which he has invented. I do not doubt that Mr. Pearce has the merit of making the discovery, but I merely write to state that about 18 months ago, when engaged in a large engineering establishment near Manchester, I made the same discovery, and made a model in wood which acted so as to give the lead with perfect accuracy both ways, and on the same principle, viz., by establishing a *proper proportion* between the length of the eccentric rod and the length of the double arms of the valve rocking-shaft. I am aware that engines have been reversed time out of mind, by means of a double lever on the rocking-shaft for working the valve, particularly coal-pit engines, and at one time Messrs. Sharp and Roberts of Manchester made the reversing gear of their locomotives on a similar plan, but so far as I know, no one has hitherto given the lead correctly both ways, by making the eccentric traverse a certain determinate angle in being shifted from one end of the lever to the other, and it is this which constitutes the merit of Mr. Pearce's invention.

I am, Sir,
Portland Street, Glasgow, Your obedient servant,
30th April, 1841. D. T.

PAPER ON HARBOURS AND RIVERS.

On the means of improving the Navigation of the River Lune up to the Port of Lancaster.

By John Rooke, Esq.*

The nautical survey of the river Lune up to the port of Lancaster, by Messrs. Stevenson, is illustrated by facts such as pure science requires in the framing of correct plans. Their report, however, is so brief, that scientific exactness could scarcely be expected, and indeed was not needed. Deepening the channel, on certain lines delineated on the plan of their survey, by the application of the dredging machine, until a specified depth and width of water is obtained, appears to be the main feature of their report.

But with some of their statements (and these concern the objects for which the report is drawn up most intimately) I am at issue; and in support of the objections here taken, all the exactness of details embodied in the survey and plan would seem to be called for. It is fortunate, therefore, that their proceedings have embraced so much exactness of information in detail. From Glasson to Heaton the diminution of fall in the channel of the Lune is about two feet and three-tenths per mile; and from Heaton to Lancaster, one foot and seven-tenths per mile. Messrs. Stevenson state in their report that "the

* This paper originally appeared in the Lancaster Guardian.

great object to be kept in view in carrying into effect the improvement of the navigation of the Lune, is the free admission of the greatest possible quantity of water from the sea." Conformably to this decisive conclusion, "The reporters beg leave particularly to point out the necessity of using much caution in encroaching on the tide-covered banks of the river, and the shutting out large portions of the tide water, and impeding the effect of that powerful, constant, and therefore most efficient of all agents in preserving the depth of navigable channels."

Directly opposed to this imperative conclusion, I should think that reliance ought to be chiefly placed upon the scour which the fresh water and tidal wave combined occasion in a fixed and compressed channel, because their united action and force is concentrated and constant: whereas, in a widely spread estuary, their action is trivial on any given line of channel, liable to change and to obstruct navigation. Hence a perfectly even, a compressed, and a securely fixed channel is that by which the navigation of the Lune may be the most effectually improved; and not by placing reliance on the scour effected by the tide chiefly, as Messrs. Stevenson would appear to intimate.

Agreeably to my view of the effect produced by the combined scour of tidal and fresh water in a compressed channel, is not silt frequently deposited along the quay of Lancaster by the tides in summer, which autumnal and winter floods of fresh water scour off again? This is so far an undeniable fact, and utterly at variance with the absolute theory put forth by Messrs. Stevenson. Let the fresh water stream be altogether withdrawn from the channel of the Lune, and in a very few years that channel might be confidently expected to become superior marsh land. Because the tidal force at its greatest power, according to the elaborate survey of Messrs. Stevenson themselves, during the flux of spring tides in the Lune, exceeds that of the reflux tides more than two fold; and hence more silt is driven upwards by such tides ("the most efficient of all agents in preserving the depth of navigable channels," as Messrs. Stevenson assert,) than the power of their reflux is adequate to carry back to the sea again. In so far all the facts collected by these engineers themselves, are utterly at variance with a theory on tidal agency, they have expressed in the most unqualified terms.

When they reported in such a manner on the navigable channel of the Lune, did they forgot that of the Clyde for fifteen miles below Glasgow? or have they witnessed the channel of the Tyne from Newcastle to Tynemouth? or that of the Avon from Bristol to King's Road? And are they unacquainted with the fact that the channel of the Thames, fixed in a compressed course by the strong ground of Tilbury on the north and Gravesend on the south, is navigable for steam boats, at all times of the tide, for seventy miles from the sea? These undeniable instances of compressed channels of navigation, may well be left to stand in evidence of themselves. Nor can I believe that a navigable funnel so perfectly true throughout, and splendid in outline as the Thames is, can have been otherwise formed than by the unerring science of a day gone by.

What have we on the opposite side of the account? The wide-spread estuary of Morecambe Bay, where there is water enough from the sea, combined with fresh water streams of great power. Then the Duddon claims our notice; and the Ribble also;—not to mention the Lune itself. The wash of Lincolnshire is another instance; and so is the Solway Firth. Now all these navigations are confessedly bad; and unimproveable except by compression. Then they might some of them rival the navigation of the Thames, the Tyne, the Avon, or the Clyde. In Kirkbride Loch, the channel of the Wampool, in five miles from the Solway Firth, loses about 15 feet of fall: it then assumes an exceedingly compressed form, and though but a trivial stream, it then maintains a dead level for three miles inland, along which high spring tides flow. Such a mass of strong evidence needs no comment.

Indeed, with a body of evidence before us so conclusive, why does the channel of the Lune undergo a diminution in depth of water from Heaton to Lancaster at all? The facts collected by Messrs. Stevenson answer this question satisfactorily. For a short distance below the quay of Lancaster the bed of the channel is found to be composed of three feet of hard gravel, resting upon fluviatile clay, or more properly speaking—compressed silt deposited by the flux tides of the sea. It is obvious that the crust of gravel which now forms the bed of the channel, has been brought down the course of the Lune by a succession of floods from the uplands, and deposited on those levels, which the combined reflux of tides and fresh water floods have not had power enough to scour out to sea. Yet on even these unequal terms, the loss of fall from Lancaster to Heaten is about 26 per cent. less per mile than from Heaton to Glasson. Had the tidal scour, therefore, on that portion of the channel where the admission of water from the sea is the greatest, and notwithstanding an accumulation of gravel from the Uplands, been equal to what it is where the tideway is the most compressed, the actual depth of water at Lancaster quay must have been three feet more than it is at present. With a body of facts and incidents so plainly in the possession of Messrs. Stevenson, for what reasons, or on what authority they adopted the theory of—"The free admission of the greatest possible quantity of water from the sea," I shall leave to their candid explanation; and I think myself abundantly justified in tearing away the entire foundation of a theory so fallacious and opposed to the improvement of navigable channels in general.

When all the evidences under which the port of Lancaster may be placed are brought into a distinct sum, the whole matter for consideration is plainly brought before the commissioners of the port, and awaits their decision. Shall the accumulation of gravel from the Uplands be allowed to continue until Lancaster ceases to be a port? Certainly not. The value of the quay and warehouses alone, not to say the prosperity of the town, and the traffic of its railway, demand the most spirited and well considered exertion, though the task left for their execution may be an arduous one.

Foremost in importance is the removal of gravel and silt from the channel of the Lune between the old bridge and Oxcliffe. Under skilful modes of carrying on the work, I should think that it might be accomplished for 6*d*. per cubic yard, as most of it could be stowed away at an easy distance. Dredging, including every expense, as estimated by Messrs. Stevenson, and taking into account penetrating an extended bed of hard gravel, may be fairly taken at 1*s*. 3*d*. per cubic yard. This so far decides in favour of the barrow, the pickaxe, and spade. Suppose then a removal of 240,000 cubic yards, at 6*d*. per yard, this head of expenditure would be 6,000*l*. In addition to this, a portion of dredging would be called for on ground where the working of the machinery was less hazardous and severe than upon hard beds of gravel. Admitting, therefore, that 80,000 cubic yards could be removed by contract at 1*s*. per cubic yard, the charge thereon would be 4,000*l*.; thus giving a total charge of 10,000*l*. In addition to these operations, were every facility given for the reclamation of land by silting it over within the channel of the Lune, 4,000 acres so reclaimed, at a deposition of 10,000 cubic yards per acre, would absorb 40,000,000 cubic yards on the whole, fix a secure channel, and give a depth of water at Lancaster quay surpassing the highest expectations, thus giving an impulse to the commercial activity of the town, and the prosperity of its manufactures.

Akehead, Wigton, Cumberland,
February 6, 1839.

Sir—Yesterday a gentleman placed in my hands Mr. Brooks' work on Rivers, Harbours, &c., and directed my particular attention to his "New Theory of the existence of Bars," among quotations of opinion on this most important subject, there appears one from a letter of mine which appeared some time back in the "Nautical Magazine," and which Mr. Brooks states are "the words of one who has devoted much time to the promulgation of his theory," *e. g.* "that egress sluicing, or scouring water is the sole cause of a bar;" that he is quite correct in this remark, your own columns bear testimony, and the records of parliament will also convey to posterity the fact that I first published to the world this novel thesis, and the equally novel principle of forming Harbours of Refuge with double entrances, without the use of back-water, a principle which is now recommended by the Commissioners in their Report of a Survey of the Harbours on the South East Coast, and for the same object, and in the same words, that I have used in reference to this affair, viz. "to afford to vessels a free ingress and egress, under all circumstances of the wind and weather."

Taking a deep interest in a matter of so much importance to this great naval and nautical nation, and numbering as I do among converts to my *thesis*, some of the most eminent scientific and practical men of the day, I beg you will be pleased to reserve for me in your next number, a space for the insertion of some observations on Mr. Brooks' Theory of Bars, as developed in the pamphlet referred to, in which observations I shall repeat my oft assertion "that bars are the effects of general, and not of partial laws, and that the bar at the entrance of Bow-creek, in the river Thames, results from the same cause as do the bars at the disemboguing of rivers in the Torres Straits, and on every other coast in the world." I state this from observations of more than 20 years made on harbours and bars in various parts of Europe, and in Africa.

I remain, your's, &c.

Henry Barrett.

London, May 25, 1841.

REVIEWS.

Treatise on the Improvement of the Navigation of Rivers, with a New Theory of the Cause of the Existence of Bars. By WILLIAM ALEXANDER BROOKS, M. Inst. C.E. London: Weale, 1841.

This work is the result of much reading and much research, deriving its materials not only from the engineering literature of England, but also from the best and latest continental writers. Although the volume is small, the labour and attention which have been bestowed are considerable, and none can peruse it without recognizing the spirit of inquiry which animates the writer. One only remark we have to make, which is, that our author does not seem to have done full justice to the contributers to this Journal, and other English writers, in omitting to mention the names of many of the parties, to whose theories he alludes.

In his introductory chapter Mr. Brooks defines several of the theories, proposed for explaining the formation of bars. First, Major Rennel's, which is that they are caused by the current losing its strength at a certain distance in the sea, and so depositing the substances carried with it.—2. Mr. Delabeche attributes it to the ocean piling up detritus on the shore —3. Mr. Rooke attributes bars to the strength of the current of the flood tide not running in the same channel with that of the ebb; or to the embouchure of the river not being freely open to the course of the tidal current.—4. Mr. Barrett's theory, as our readers know, is, that they are caused by the conflicting action of effluent currents passing into the ocean at right angles to the shore.—5. Another, and the most favourite theory is an imagined insufficiency of backwater.—6. An opinion entertained abroad is that bars arise from the streams in their approach to the sea spreading in surface and diminishing in depth, so as to deposit the sands.—7. Colonel Emy, an eminent French engineer quoted by our author, attributes these obstacles to the ground waves, or *flots de fond*.—8. We now come to the theory put forward by Mr. Brooks, which we shall let him give in his own words.

An accurate examination of the state of a bar river will exhibit a great irregularity of its surface at low water; in lieu of the river presenting at that period a longitudinal section of a succession of inclined planes, described in the preceding description of rivers free from bars, as becoming more and more gentle in proportion to their proximity to the ocean, it will be often found that the declination or slope of some of the upper reaches is less than those nearer the ocean; and the fall at low water in the lower reaches of the river is always so great, as to produce a striking difference in the vertical rise of tide, even at a short distance from the sea; and attendant upon this defective state of the section presented by the surface of the river at low water, is a great extension of the duration of the ebb, beyond that of the upward current of the flood tide.

The river being in this irregular state, the process by which the bar is formed may be thus described.

During the period of the first quarter flood, the current, in lieu of being able to take its natural upward course, as in rivers where no bar exists, is opposed, or effectually checked, by the effluent backwater; the declination of the stream in the lower division of the river presenting a head which insures a strong downward current, long after the tide would have been able to maintain an upward course, provided the backwater had had a free discharge. At this period the flood tide, by reason of its greater specific gravity, occupies the lower stratum of the tide-way, and like a wedge endeavours to force its course up the channel, which it is unable to effect, but merely elevates the lighter effluent water, the lower strata of which, being checked by the opposition of the tidal water, yields to the latter the sand or other materials, which it was capable of holding in suspension, previously to its encountering the conflicting action of the flood-tide; and where this takes place the bar is formed.

To the theory of Major Rennel (No. 1,) Mr. Brooks objects that it is insufficient because the operations described as producing bars take place in all rivers, even in such as having their waters most abundantly laden with sand or mud, are yet free from bars. On Mr. Delabeche's (No. 2), Mr. Brooks says that the action of the waves cannot be the cause, as bars are found in the most sheltered situations, while other rivers abounding with silt are nevertheless free from deposits in the most furious seas. To Mr. Rooke and Mr. Barrett (Nos. 3 and 4), the objection of our author is that in rivers subject to great variation at their entrance, the bar is always found to exist independently of the direction of the discharge into the sea. The backwater theory (No. 5), is confessedly insufficient, the mightiest rivers of the globe presenting staggering exceptions. To the 6th, it is opposed that in the Mediterranean no current is ever opposed to any stream, and that consequently the repose supposed to take place at the meeting of the currents cannot exist. Further, that in the ocean one of the two currents overcomes the other. Mr. Brooks objects to the ground waves or *flots de fond* acting on sudden elevations of the bed of the sea in the manner assumed by Colonel Emy, opposing to it the received opinion that breakers are formed immediately on any portion of the wave meeting violently the vertical face of the obstruction. In support of this view an appeal is made to the geological formation of the north coast of Yorkshire, where nothing is found to corroborate the Colonel's hypothesis. The case of the Adour quoted by Colonel Emy is well shown by Mr. Brooks to be an influence of local causes.

With regard to rivers being free from bars, Mr. Brooks supports Mr. Rooke's views, giving a good definition that whenever a navigable river approaches to the form of a simple inlet for the reception of the tide so far as regards the longitudinal section, presented by its surface at low water, it will either have no bar, or be but lightly obstructed by one. The same, he observes, may be said of those seaports or pier harbours, which though free from bars in their natural state, are well known to become encumbered by them immediately on the introduction of an artificial scouring power. The views of the previous writers, Mr. Brooks has carried out still further, and we are prepared to concur in much that he says. He remarks that

Resuming the investigation into the state of a river, whose entrance is free from a bar, we shall find that, from its junction with the ocean, a long line of navigable course exists with an extremely gentle fall, or slope of its surface, at low water; the river is in this case in a proper train, its longitudinal section presenting a succession of inclined planes, becoming more and more gentle, as they approach the ocean; and the lower course of the river, from the slightness of its fall, approximates to the condition of a frith, or deep inlet, of the coast, or to that of one of those large natural or artificial harbours, which, being mere tidal receptacles, wherein the influx and efflux take place in equal times, are necessarily free from bars.

The river being in this perfect state, as regards the slope of its surface at low water, a consequent attendant upon the latter will be an equal duration, or nearly so, of the period taken up by the flow of the flood tide, with that of the ebb, in the lower reach of the river; by the term flow being understood, the direct upward course of the current of the flood tide, immediately after the true time of low water.

Our author having propounded his theory, goes on to propose his remedies for the cases in which bars exist. His first remedy is to make the bed of the river of more regular inclination.

By this natural elongation of the course of rivers by the deposit of alluvial matter, a gradual amelioration of the navigation must take place, inasmuch as that elongation is necessarily attended with a more gradual junction with the waters of the sea, or the diminution of the velocity of the current at the point of discharge; we have therefore only to assist the operations of nature by directing the course of the current, and thereby the position of the deposit of the alluvions, to insure that the latter shall act beneficially and not prejudicially to the navigation.

He then goes on to provide for other cases.

In a tidal river, where a bar exists, and the reduction of the declination of the low water surface cannot be effected, by reason of a long length of rocky bed, too costly to remove, the only means available for its improvement is an artificial elongation of its course, by piers or other works, to bring the mouth of the river within the influence of a stronger current.

Where the declination of a river is great in its lower reaches, the result of any cut near the embouchure of the river, which is not attended by a simultaneous reduction of that declination, must be the increase of the bar. It is however to be observed, that the natural attendant effect of the shortening the course of the current, is the more free discharge of the water and abasement of the level of the surface of the current; and wherever this latter circumstance does not take place, it is solely due to the presence of some geological feature, such as rock or marl, which the current, when unassisted by art, is unable to act upon.

Upon the use of artificial scouring power, where used with the view of increasing the effect produced by the natural backwater of rivers, we find it observed.

Assuming, therefore, that the volume of the natural backwater is so small as to be inadequate to maintain a sufficient depth in the harbour for the maritime wants of the port, and that the aid of an artificial scouring power be requisite, still the latter should not be made use of, except during that period of the ebb when its effect is to remove seaward the matter held in suspension by the effluent water.

If, therefore, any portion of the artificial backwater be discharged during still water, or during any period of the flood tide, we may anticipate a rapid deposit, or accumulation on the bar.

In order to secure the utmost useful effect from an artificial scouring power, it is essential that its action be prolonged to a position which is within the range of a strong tidal current, or within the reach of the effect of the prevailing onward impulse by the surf, during on-shore gales.

Where the scouring power terminates *negatively*, if I may use the expression advanced by Major Rennel, or where the effect of the scouring power is unable to extend into a true tidal shore current, it is unreasonable to expect its utmost useful available result.

Thus, supposing the bar produced by a scouring power be situated in a sheltered situation in a bay, there can remain no hope for its improvement until the place of deposit be removed into the true run of the ebb tide.

With regard to the theory of Mr. Brooks, in our opinion it is as far as that of any of his rivals from being of universal application: in fact we doubt very much whether any such theory will ever be found as one which shall provide for all cases. We must, however, say unhesitatingly, that Mr. Brooks has by developing this theory made an important contribution, not merely to the progress of the investigation, but to the resources of engineering, for this theory will admit of a more general application than any other. We do not like Mr. Brooks condemning all the other theories propounded, for we certainly are of opinion that both the theory and the practice are highly in favour of some of them, as regards their application to such cases as come within their sphere.

The chapter on the causes of the existence of shoals in the beds of rivers, is a highly amusing chapter of controversy on most of the cases which now disturb the engineering world, such as the Clyde, the Wear, the Thames, the Tyne, the Lune, the Dee and the Mersey; the mere mention of which subjects, by the bye, is sufficient to show how much the attention of the profession, and the interests of the public, are engaged in investigations of this nature. The chapter on the causes of the bore, egre, rollers, pororoca, bar or mascaret, is a good contribution to an important investigation; we must, however, call our author's attention to the Solway, and several other English cases which he has not mentioned. Having thus called the attention of our readers to many points, to which we cannot refer at greater length, we must also inform them, that they must not infer from our notice that Mr. Brooks' work is one of theory only, for they will find it of great value on numerous practical points of harbour engineering.

We do not treat Mr. Brooks' work as a complete treatise on the improvement of rivers, and if we did so we should perhaps do him injustice, as he seems principally to have had in view the statement of his own theories, but we cannot leave it without pointing it to our readers as one of the best works on the subject, which has yet been written, and one which they will find calculated to give them much pleasure and much instruction.

On the Subject Matter of Letters Patent for Inventions. By Thomas Webster, Esq., of Lincoln's Inn, Barrister at Law. London: Crofts and Blenkarn, 1841.

There have been few subjects more debated than that of the operation of the Patent Laws, from which serious difficulties have been felt by all classes of inventors. This has caused a strong demand for Reform in the Patent Laws, an outcry in which we are little disposed to join, as we are more inclined to think that the evils have arisen from the mystifications and misconception of the law, than from any defect in the law itself. No one has exerted himself more than Mr. Webster has done to clear up this subject, particularly in his former work, "the Law and Practice of Letters Patent for Inventions," and he has continued his exertions to the same laudable end in the small volume now before us. Here he shows us what is the subject matter of Letters Patent, supporting the general doctrines by adducing a great number of cases decided. For the sake of simplification he classifies the proper subjects for a patent under three distinct heads.

I. An arrangement, combination, or composition of matter; the particular arrangement, combination, or composition being the essence and substance of the invention.

II. An arrangement, combination, or composition of matter, with the view of carrying out into practice certain truths, laws, or principles, the particular arrangement, combination, or composition, not being of the essence or substance of the invention, except as in connexion with and subsidiary to the truths, laws, or principles, which are to be so carried out into practice.

III. An application and adaptation of natural or known agents, and of known substances or things.

Mr. Webster next proceeds to describe what constitutes an invention.

The subject-matter of letters patent must possess the incident of novelty, or the principles of the common law and the words of the statute will not be complied with; and further, the result to which it leads must be a new manufacture. But every novelty is not an invention which may be the subject-matter of letters patent; the change must be such as may have resulted from the exercise of or given scope for thought, design, and skilful ingenuity. It is not necessary that either thought, design, skill, or ingenuity, should have been exercised—the invention or discovery may have resulted from guess or accident; and in a great number of cases the whole invention is but the conception of the idea; and whatever may have been the thought or labour before the idea was conceived, or the result attained in practice, yet inasmuch as the result itself gives no evidence of thought or labour, neither may have been exercised. This is peculiarly the case with many of the inventions which are applications of known agents and things, and described above under the third class. In most of these cases the practical application of the idea is easy and simple, and will suggest itself as soon as the idea; in fact, the whole invention is realized as soon as the idea is conceived. In these cases then it is only necessary that the possibility of thought, design, and skilful ingenuity, having been exercised, should not be excluded. The simple substitution of one material for another, as brass for copper, in any construction, may or may not be an invention or discovery which could be the subject-matter of letters patent. Suppose a machine for making iron nails in a particular manner—the application of that machine to making copper nails, there being no adaptation, no change in any part of the manufacture but the substituting of copper for iron, the machine being worked precisely as before, could not be the subject-matter of letters patent. Cases of this kind must be determined by other considerations, as the utility of the change.

This definition Mr. Webster supports by several cases in which the same doctrine has been laid down by the law authorities, and then proceeds in a similar manner to define what is novelty, non-use, and utility in a patent, concluding with a review of practical proceedings.

The various matters treated of in the preceding pages, may be illustrated and confirmed by a review of the practice of obtaining letters patent. The party soliciting the letters patent represents to the crown that he is in possession of an invention, which, as he believes, is new, and will be of great public utility. Thus the conditions of novelty and of utility are at once introduced as material and essential; the failure of either of them would be a ground for avoiding the letters patent, as having been obtained on false suggestion. Upon this representation, and on the consideration that it is entirely at the party's own hazard, whether the invention is new, or will have the desired success, and that it is reasonable for the crown to encourage all arts and inventions which may be for the public good, the law officer of the crown recommends the grant, with a proviso requiring the inventor within a certain time to cause a particular description of the nature of his invention, and in what manner it is to be performed, to be enrolled in the court of Chancery. This proviso gives rise to the specification, upon which instrument so much depends, for if it does not satisfy the terms of this proviso, and, further, is not a full and fair disclosure of all the inventor knows, the letters patent will be void.

We are very glad to find that Mr. Webster's well known scientific attainments have induced him, to turn his attention to the study of so important a branch as that of the Law of Patent Invention, and we have no doubt that he will find himself amply repaid by the results for the labour and talent he has devoted to these researches, while to the patentee it will be a great advantage to find that they have a barrister, who is so well acquainted with every department of the subject, one who unites to the acumen of the barrister, a practical knowledge of mechanics and science.

The Mechanics of Engineering, intended for use in Universities and in Colleges of Engineers. By William Whewell, B.D., Professor of Moral Philosophy in the University of Cambridge. London: Parker, 1841.

If we wanted any proof of the high estimation in which engineering now stands as a profession, we shall find it in the present work, where a man of Professor Whewell's attainments feels himself called upon to contribute towards its elementary instruction. The motives which have urged him to this work are so laudable, and they are expressed in a manner so well calculated to give sound counsel to the profession, that we think we cannot do better than insert the following extract.

Various circumstances at the present time make it desirable that the subject of engineering should be treated in such a mode that it may be made a satisfactory part of a liberal education. I refer not only to the attempts now so laudably making in various quarters to improve the professional education of engineers, but also to the desire which is more and more felt in the country, that what our students learn of mathematics in their university career should have some meaning in real life. *In the science of mechanics it has especially happened that the mathematical study of the subject has been pursued with very little regard to its practical application. The consequence of this is, not only that our theoretical teaching is of little value in preparing a person for any part of the business of engineering, but also, that it is of little value as intellectual discipline.* For the student has not been taught to seek and to find, in the mechanism which he sees about him, the exemplification of his theoretical principles; and hence he never learns to think steadily upon the subject, and when his days of pupilage are past, ceases to think upon it at all. This could hardly happen if his education made him familiar with principles readily applicable to every machine and every structure which came in his way; for in that case he would be constantly stimulated to understand what he saw; and clear views of mechanical relations would become part of the habits of his mind. The relations of space once learnt in geometry do not fade away from our thoughts, because throughout our lives we continue familiar with exemplifications of them in geography, astronomy, and other common pursuits. If the common problems of engineering were to form part of our general teaching in mechanics, this science also might become a permanent possession of liberally educated minds. Every roof, frame, bridge, oblique arch, machine, steam-engine, locomotive carriage, might be looked upon as a case to which every well-educated man ought to be able to apply definite and certain principles in order to judge of its structure and working. And this would, I conceive, be an improvement, not only in professional, but in general education.

Motives, expressed in this modest manner, deprive us of any observations on a work in which Mr. Whewell has shown himself anxious to consult his own reputation and the wants of the public. There are too many who think that a mathematician or a calculator is an engineer, and are too ready to despise practical attainments in the pursuit of abstract studies, so that we feel much indebted to Mr. Whewell, himself a mathematician, for giving so necessary a caution to those who might be led away by the study of a book so delightful as his, into realms so remote from engineering. Mathematics and engineering are roads which for a certain distance are mutual, but we feel obliged to give a hint that there is a point of divergence when the wayfarer has the choice of two separate and far distant paths.

Plans for the Formation of Harbours of Refuge, Improvement of Rivers, and Suggestions for Ameliorating the Condition of Seamen, Preventing Shipwreck, and Miscellaneous Matter. Illustrated with Plates and Charts. By Capt. J. N. Taylor, R.N., C.B. Plymouth, 1840.

Capt. Taylor's plan for the formation of harbours of refuge is by the use of a floating breakwater, this he proposes to secure by moorings of logs of timber shackled together, so as to avoid the inconvenience of chain moorings. The work before us is more accurately described by the title prefixed to the first page, Series of Papers, &c., being a collection of memoranda on naval engineering, and naval officers generally. It includes descriptions of several of Captain Taylor's inventions.

Gas Lighting.

1. *A Practical Treatise on Gas Lighting, with Twenty-two Plates.* By Thomas S. Peckston, R.N., C.E. London: Hebert, 1841. (Third Edition).
2. *A Practical Treatise on the Manufacture and Distribution of Coal Gas, illustrated by Engravings from Working Drawings.* By Samuel Clegg, jun., C.E. London: John Weale, 1841.

We have no doubt that our readers who look at these works will do as we have done, pair them together. The names of Clegg and Peckston are extensively known as connected with the subject of gas lighting, so that works emanating from either of them must be hailed by the student and professional man as useful additions to the engineering library. "Arcades ambo" as they are it is difficult for us to decide upon their claims, so that we must earnestly recommend to our readers to purchase both works, and see if they can more readily bring the matter to an issue. Mr. Peckston has long written on gas lighting, and Clegg has been intimately connected with the improvement of the system almost from its very invention, having been one of the first to carry it out on a large scale—what he has done since all the world knows. The work of Mr. Peckston is in its third edition, a circumstance which renders it unnecessary for us to urge claims on which the public has already pronounced, and which will excuse us for any apparent neglect in devoting more of our attention upon this occasion to the first effort of the younger candidate. To say that the profession have looked forward to young Mr. Clegg's work with interest, is to say no more than the bare truth, for the list of subscribers shows the names of all the first gas engineers in the country, who thus have already expressed their confidence as to his competency for the task he has assumed. They could not well doubt this, for he comes to the subject armed not only with his own knowledge and experience, but with those of his father, to whose valuable memoranda he has had ready access.

The distribution of both works is much the same, the introductory chapters giving a short history of the progress of the art, a sketch of chemistry as applied to this manufacture, and an account of coal. From the statements of Mr. Peckston and Mr. Clegg, it appears that the late talented Mr. Murdoch was the first person who introduced gas lighting for practical purposes. He first lighted his own house at Redruth, in Cornwall, in 1792; afterwards in 1798 he erected an apparatus for a similar purpose at the manufactory of Messrs. Boulton and Watt, at Soho—a pleasing reflection to find that the great improvers of the steam engine should also be the first to patronize the introduction of lighting by gas against all the prejudices and superstitious feeling of the day—the next place lighted, by Mr. Murdoch, upon a large scale, was a cotton manufactory at Manchester in the year 1805, the apparatus for which was made at the works of Messrs. Boulton and Watt. A paper by Mr. Murdoch describing the apparatus was read before the Royal Society, February 25, 1805, from which paper we collect that the number of burners employed in the manufactory amounted to 271 argands and 633 cockspurs, each of the former giving a light equal to four candles, and the latter a light equal to 2¼. It appears, that at the same time Mr. Murdoch was engaged in fitting up the gas apparatus at the above manufactory, that Mr. Clegg (the father of the author), was engaged in a similar manner for lighting a cotton mill near Halifax, which Mr. Clegg states was lighted a fortnight before the cotton mill at Manchester, a circumstance however which does not militate against the claims of Mr. Murdoch as being the first who introduced gas lighting for practical purposes. The next place lighted was the Catholic College at Stonyhurst, Lancashire, (in 1807, 1808), when Mr. Clegg had an opportunity of making several experiments for purifying the gas, using for that purpose lime water in a separate vessel, which was to render the gas pure. We now come to the time when gas was attempted to be introduced upon a large scale for lighting the public streets, when we find ourselves indebted to Mr. Winsor for his indefatigable zeal, in exerting himself (even as early as 1803-4,) by lecturing and other means, to overcome the prejudices of the public; through his exertions a company was formed in 1809, called "The London and Westminster Chartered Gas Light and Coke Company," in that year application was made to Parliament for incorporating the company, but from the obstinacy and prejudices of several parties, as is too frequently the case in new undertakings, the Bill was opposed, and it was not until 1810 that an Act was obtained. During this time Pall Mall was lighted up, but so far from prejudices being allayed, the project was treated with derision by many of the scientific men of that day. Mr. Clegg next proceeds to detail the difficulties the Company had to overcome in the erection of their works, and introducing the gas for public purposes, and it was not until 31st December, 1813, that the Company were able to light any public place, when they lighted Westminster Bridge. Thus we see that a period of 21 years was lost from the date of the first introduction by Mr. Murdoch, before gas was generally adopted.

The early part of Mr. Clegg's volume is occupied with a dissertation on "Chemistry as applied to the Manufacture of Coal Gas," followed by a chapter on "Coal," which affords much valuable information.

The kinds, or rather the different names, of coal used at the London Gasworks are, South Pelaw, Ellison's Main, Felling Main, or East Garesfield Main, Dean's Primrose and Pearith's Wall's-end. Most of the Companies have the facilities of water-carriage, and purchase their coals at the pit for about 7*s*. 6*d*. per ton, and charter a vessel from 8*s*. to 11*s*. per ton, according to the time of the year. If the gas-works are far from the water-side, and they purchase their coals at the market, the above would fetch from 17*s*. 6*d*. to 18*s*. 6*d*. per ton; and to a large consumer, for cash, 5*s*. would be charged for cartage, making a total of 22*s*. 6*d*. to 23*s*. 6*d*. If the gas-works are at the water side, the charges would be as follows:—

	s.	*d.*
Cost of coal at the pit mouth, say	7	6
Freight and loading	8	0
Lighterage from ship to wharf	0	10
Gang of men carrying from barge to works, per ton, according to distance	1	0
Duty 1*s*. 1*d*., and weighing 1½*d*. . . .	1	2½
	18	6½

At Birmingham and in the neighbourhood the price for Staffordshire coal is about 8*s*. 6*d*. per ton, including all expences.

In Scotland the prices, per ton, paid for the different kinds of Parrot coal at the places where they are shipped, are as follows:—

	s.	*d.*		*s.*	*d.*
Lesmahajo . .	17	0	Marquis of Lothian	17	6
Monkland . .	16	0	Capledsea . .	14	0
Torry Burn .	12	0	Halbeath . .	12	0
Wemyss . .	13	6	Lochgelly . .	10	0

The price of coke in London varies according to the demand; to retailers who fetch the coke it is now about 16*s*. per chaldron, to private persons 18*s*., and if delivered, from 21*s*. according to the distance. At West Bromwich coke is considered on an average to be worth 4*d*. per bushel.

Under the head of "Advantages of Gas," Mr. Clegg has afforded us some sound practical observations and calculations, which cannot fail to be highly appreciated by the engineer: the following calculation of the cost, outlay and income of a small gas work is useful, as it shows at what a comparatively trifling expense villages might be lighted.

If the number of lamps required is known, the materials necessary for the production of the gas to supply those lamps are known also. The profit and loss of such establishments in actual operation may as surely be relied upon as that given upon paper.

Upon a well-regulated system the cost of producing every 1000 cubic feet of gas with the same coal will not vary one penny the whole year round; the quantity of gas made will be adequate to the demand, and no more. The wear and tear of the machinery will be exactly that which was anticipated, and therefore the annual outlay will be known; the sale of the products of the establishment may be depended upon with equal certainty, and the income known; the profit arising from the difference is thus ascertained. I will give as an example the results of a small gas establishment erected in the country.

Leaving a Profit of	£186	7	9		£191	7	10

The equal results of these two years is not peculiar to this establishment; there are many of much greater extent that can compare with it.

The chapter on "Retorts," describes the different plans that have been adopted, their faults and advantages, their mode of setting, construction and cost, and is illustrated with some beautiful engravings and wood cuts. The annexed engraving shows the construction of a retort, and the manner in which it is set, when a small quantity of gas is required.

In country towns, where the quantity of gas made during the winter seasons does not exceed 10,000 cubic feet in twenty-four hours, the retorts must be set singly, as represented in Figs. 1 & 2., the flue passing beneath and over the retort, which rests upon a half-brick arch, cut flat at the top to receive it; the end is guarded by a thick fire-tile.

Fig. 1.

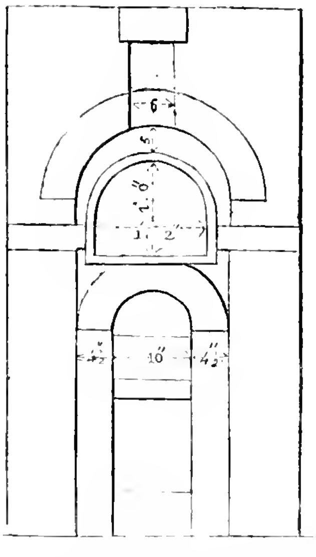

Fig. 2.

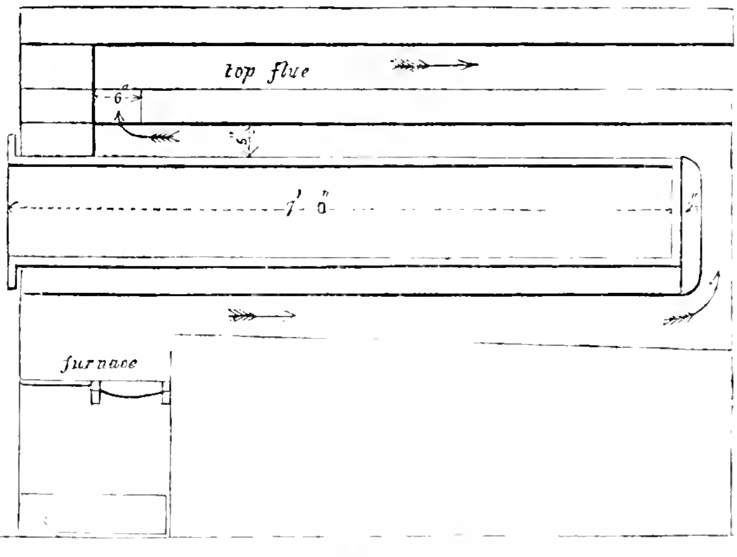


Mr. Croll, the superintendent of the Chartered Gas Company's works, (Brick Lane station), has introduced a system of using the coke as fuel while red-hot. The charge from the retorts is drawn into a wrought-iron carriage, and immediately taken to those furnaces which require feeding. He informs me, that the saving effected by this simple process is equal to 10 or 12 per cent.; I should conceive it to be fully that. The reason is evident; because when a quantity of black coke is thrown on the previously heated mass of fuel, the flues will to a certain extent become cool, since the heated air is absorbed. When hot coke is thrown on, no absorption takes place, and the flues are kept up at a uniform temperature.

Mr. Clegg speaks very highly of Mr. Grafton's fire clay retort.

In England and Scotland the fire-clay retort has superseded the use of metal in no less than forty towns; in some instances it has lasted for the extraordinary period of twelve years; while, during this time, at all other works where the invention is not yet used, it may be asserted that iron retorts have been renewed as many times. The oven or D-shaped retorts are found to be the most advantageous, being made with a capacity to carbonize one cwt. of coal every hour. They can be constructed either to be heated by coke ovens, or coke furnaces, or by the burning of tar: with coke ovens they are more durable. It appears that clay retorts, when constructed upon such a scale as that given in the plate, have great power to *retain* their heat when brought to the proper temperature for decomposing the coal, viz. 27° of Wedgewood.

This power of retaining heat is proved by constant practice to produce 1000 cubic feet of gas per ton from the same coal more than the average of the London produce, and the consumption of fuel is not more than 22 or 23 lb. of coke to carbonize 100 lb. of Newcastle coal, taking the average of six months' working; it is even less with the Staffordshire or Lancashire coal.

We have now shown by our extracts the value of this excellent work, and in the next number we shall proceed to notice the remaining part of Mr. Clegg's book; in the mean time we hope that both the volumes will be in the hands of all those who are desirous of obtaining information on the subject of gas works.

Before we close the present notice, we must offer a just tribute of praise to Mr. Gladwin the engraver, for the very clear manner in which he has executed the plates in Mr. Clegg's work, which are so beautifully delineated, that they cannot fail to convey, even to the non-professional observer, an accurate knowledge of the construction of the apparatus which they delineate.

XENOPHON ON THE ATHENIAN MINES.

Extracted from the Translation by Walter Moyle, Esq., of the Pamphlet on the Improvement of the Revenue of Athens.

Our silver mines alone, if rightly managed, besides all the other branches of our revenue, would be an inestimable treasure to the public. But for the benefit of those who are unskilled in inquiries of this nature, I design to premise some general considerations upon the true state and value of our silver mines, that the public, upon a right information, may proceed to the taking of such measures and counsel as may improve them to the best advantage.

No one ever pretended from tradition, or the earliest accounts of time, to determine when the mines were first begun to be wrought, which is a proof of their antiquity; and yet, ancient as they are, the heaps of rubbish which have been dug out of them and lie above ground, bear no proportion to the vast quantities which still remain below, nor does there appear any sensible decay or diminution in our mines; but as we dig on, we still discover fresh veins of silver ore in all parts, and when we had most labourers at work in the mines, we found that we had still business for more hands than were employed.

Nor do I find that the adventurers in the mines retrench the numbers of their workmen, but purchase as many new slaves as they can get; for their gains are greater or less, in proportion to the number of hands they employ. And this is the only profession I know of where the undertakers are never envied, be their stock or profits ever so extraordinary, because their gains never interfere with those of their fellow traders.

Every husbandman knows how many yoke of oxen and servants are necessary to cultivate his farm, and if he employs more than he has occasion for, reckons himself a loser; but no dealer in the silver mines ever thought he had hands enough to set to work.

For there is this difference between this and all other professions; that whereas in other callings, for instance, braziers and blacksmiths, when their trades are overstocked, they are undone, because the price of their commodities is lowered of course, by the multitude of sellers; and likewise a good year of corn, and a plentiful vintage, for the same reason do hurt to the farmers, and force them to quit their employment, and set up public houses, or turn merchants or bankers. But here the case is quite otherwise, for the more ore is found, and the more silver is wrought and made, the more adventurers come in, and the more hands are employed in our mines. A master of a family indeed, when he is well provided with furniture and household goods, buys no more, but no man was ever so overstocked with silver, as not to desire a farther increase; if there are any who have more than their occasions require, they hoard up the rest with as much pleasure as if they actually made use of it. And when a nation is in flourishing circumstances no one is at a loss how to employ his money; the men lay it out in fine armour, in horses, and in magnificent houses and buildings; women lay it out in great equipages, costly habits and rich clothes. And in accidents of war, when our lands lie fallow and uncultivated, or in a public dearth and scarcity, what reserve have we left to apply to but silver, to purchase necessaries for our subsistence, or hire auxiliaries for our defence? If it be objected that gold is as useful as silver, I will not dispute it; but of this I am sure that plenty of gold always lowered its value, and advanced the price of silver.

I have insisted the longer upon these general reflections to encourage adventurers of all kinds, to employ as many hands as possible in a trade so advantageous, from these plain considerations that the mines can never be exhausted, nor can silver ever lose its value.

That the public has known this long before is evident from our laws, which allow foreigners to work our mines upon the same terms* and conditions as our own citizens enjoy.

But to draw this discourse more immediately to the subject of my present consideration, which is the maintenance of our citizens, I will begin to propose those ways and means by which the silver mines may be improved to the highest benefit and advantage to the public. Nor do I set up for the vanity of being admired for an author of new discoveries; for that part of my following discourse, which relates to the examples of the present age, lies obvious to all the world; as for what is past it is matter of fact, and every man who would be at the pains of inquiring might inform himself.

It is very strange that after so many precedents of private citizens of Athens, who have made their fortunes by the mines, the public should never think of following their example; for we who have heard that Nicias, the son of Niceratus, had a thousand slaves employed in the mines, whom he let out to Sosias the Thracian, upon condition to receive an obolus a day, clear of all charges for every head, and that the same complement of workmen should be always kept on foot. In like manner Hipponicus had six hundred slaves let out at the same rate, which yielded him a revenue of a mina a day, and Philemonides three hundred, who brought him in half a mina a day, and many others made the same advantage, in proportion to the number of slaves they possessed. But what need have we to appeal to precedents of an older date, when at this day we have so many instances before our eyes of the same nature?

In the proposals which I offer, there is only one thing new, namely, that as private men have a constant revenue coming in from the slaves whom they let out to work in the mines; so the public, in imitation of their example, should purchase as many slaves to be employed in the same manner, as will treble the number of their own citizens.

(Xenophon then goes to argue on the advantages of this plan.)

To demonstrate that the mines would take up a greater proportion of slaves to work them, I appeal to the authority of all the living witnesses who remember, what numbers of workmen were employed in them before the taking of Decelea* by the Lacedemonians. And our silver mines that have been wrought for so many ages, with such numbers of hands, and continue still so far from being drained or exhausted, that we can discover no visible difference in their present state from the accounts our ancestors have delivered down to us, are undeniable proofs of my assertion. And their present condition is a good argument that there never can be more hands at work in the mines than there is employment for: for we dig on still without finding any bottom or end of our mines, or decay of our silver ore. And at this day we may open new mines as well as in former ages, and no one can determine whether the new mines may not prove richer than the old ones. If any one demands why our miners are not so forward in pursuit of new discoveries, as formerly; I answer, it is not long since that the mines have begun to be wrought afresh, and the present adventurers are not rich enough to run the risk of such an undertaking. For if they discover a rich mine, their fortunes are made; but if they fail, they lose all the charges they have been at; and this consideration chiefly has discouraged the adventurers from trying an experiment so dangerous.

(Xenophon here urges upon the state to take measures for discovering new mines.)

Companies of private adventurers may carry on the same trade in a jointstock, nor is there any danger that they and the national company will interfere with one another; but as confederates are strengthened by their mutual assistance to each other, so the more adventurers of all kinds are employed in the mines, so much larger will be the gains and advantages to all.

(Our author again dwells upon the advantages of his plan, and in allusion to the probable effects of a foreign war he says)

And I have reason to believe that it is possible to work our mines in the conjuncture of a foreign war, for they are covered on the south by a strong citadel in Anaphlystus, and on the north sea by another in Thoricus, and these two fortresses lie at the distance of but 60 furlongs from one another. But if a third fort were built upon the top of a mountain, in the middle of the two former, the three works would meet together, and other silver mines would be inclosed in a circle, and guarded on all sides, and the workmen at the first notice of an invasion might retire to a place of safety. But if we are invaded by more numerous armies, our enemies may make themselves masters of our corn, wine, and cattle that lie without the works, but if they possess themselves of our silver mines, what can they find to carry off more than a heap of stones and rubbish? But how is it possible for our enemies to make an inroad upon our mines? for the city of Megara, which lies nearest is above 500 furlongs from them; and Thebes which is nearer them than any but Megara, is more than 600 furlongs distant from them.

(We here again omit what Xenophon says about the advantages of his plan.)

The revenue arising from our slaves would not only make a considerable article in the charge of maintaining our citizens, but by the vast concourse of people from all parts, the customs of the fairs and markets at the mines, and the rent of our public buildings and melting houses, and many other heads, would produce a mighty income to the state. The state, upon such an establishment, would be peopled with a prodigious number of inhabitants, and the value of lands at the mines would be as high as those that lie near Athens.

---

* This was a tribute of a twenty-fourth part of the silver found, according to Suidas.

* When 20,000 Athenian slaves deserted.

ON BURNING GAS FOR HEAT OR ILLUMINATION.

By Sir John Robison, K.H., Sec. R.S.E., M.S.A.

The two following papers were read, March 1839, before the Society of Arts for Scotland.

On the best means of Burning Gas for supplying Heat.

"*Vix ea nostra voco.*"

When carburetted hydrogen gas is employed in producing heat, it is seldom required that it should, at the same time, give out light; the combustion may, therefore, be managed in any way which may be convenient without seeking to preserve the illuminating power. It appears to have occurred about the same period to the late Dr. Duncan and to myself, that, by passing a current of gas, mixed with atmospheric air, through a wide vertical tube, having its upper end covered by a diaphragm of wire gauze, and by kindling the mixture as it escaped through the interstices of the wire cloth, a convenient stove might be formed for culinary purposes. Dr. Duncan applied some small apparatus on this principle to pharmaceutical operations in his class-room, and I had my kitchen furnished with a range of large stoves, which were intended to supersede the use of French charcoal stoves in various culinary processes. In both cases the success has been perfect, and the same principle has since been adopted with advantage in a variety of processes in the useful arts, where this neat and cleanly method of applying heat has rendered it a valuable acquisition to the work-shop.

The form of the apparatus may be varied in any way to suit the particular process to which it is to be applied; as all that is essential is, that a current of the mixed gas and air shall rise through wire-cloth, and that the proportion of gas to atmospheric air shall never be so great as to allow of the flame becoming yellow, as, with this precaution, the combustion of the carburetted hydrogen will be complete, and no deposit of soot will take place on cold bodies when set over the flames; the proper quantity of gas in the mixture is easily determined by the stop-cock belonging to each stove.

For ordinary culinary purposes, the cylinders may be thirty inches long, and three to four inches diameter, and the wire-cloth for the tops should have about thirty wires to the inch. That which is manufactured for safety-lamps answers well for this purpose.

Whenever, from accidental injury or decay, a hole takes place in a diaphragm, it is no longer possible to use it: as, when lighted, the flame passes through the fracture, and communicates with the jet at the bottom of the cylinder, which then burns like an ordinary gas-light, and, like it, would blacken the surface of any cold body presented to it. The wire-cloths, if not broken through by violence, will last for months although in daily use; and, if covered by a layer of coarse sand or pounded limestone, will continue serviceable for an unlimited period.

When more intense heat is required than is attainable by the unaided combustion of the mixed gases, recourse may be had to various forms of blow-pipes: and when a large volume of such flame is to be employed, the current of atmospheric air may be urged by double bellows. A very efficient apparatus on this principle is to be seen in the laboratory of Dr. D. B. Reid.

It is to be regretted, that such applications of gas are not more generally known and introduced into work-shops, as there are numerous processes in the arts in which they would afford facilities to the workman which he can scarcely command by any other means. For example, in the hardening of steel tools, it is well known that a piece of bright steel, when heated to redness in a forge or muffle, is subject to oxidation, and that a black scale remains after hardening, which it is difficult to remove without some injury to the work, as in the case of a screw tap; whereas, if the same piece of steel be heated in a flame of the mixed gases, where there is no free oxygen to attack its surface, it may be *made and kept* red hot without any injury to its finest edge; it will be discoloured, but without losing much of its polish. The artist has also the advantage of a distinct view of the article while it is being heated, and the power of withdrawing it from the flame the moment it has acquired the proper colour, which, in the hardening of cast steel cutting tools, is of great importance.

Many attempts have been made to apply carburetted hydrogen and pure hydrogen gases to the purposes of warming buildings, and various forms of stoves have been proposed, on the understanding, it would appear, that, by applying the flame of the gas to metallic bodies, an increased degree of heat would be communicated by them to the atmosphere around. A little consideration will show, that however the *distribution* of heat may be modified by such contrivances, there can be no increase of the heating power; and that when a certain measure of gas is fairly burned, the heat evolved into the apartment will be the same whether the flame be disposed as a light, or made to play against metallic plates or other combinations of apparatus. In all cases where the products of the combustion are allowed to mix with the atmosphere of the apartment, without provision being made for carrying them off by ventilation, the effects of such processes must be more or less deleterious to health, according to the proportion these products bear to the mass of air they mix in. On the whole, it may be assumed, that this mode of heating apartments is the most expensive, the least efficient, and, excepting that by Joyce's charcoal stove, the most insalubrious that can be resorted to.

On the best method of Burning Gas for the purpose of Illumination.

The theoretical principles on which carburetted hydrogen gas may be used with the best advantage, for the purpose of domestic illumination, have been so well laid down by the late Dr. Turner, and by Dr. Christison, as well as by other chemists, that it would be superfluous to enter at all on this part of the subject in a paper, the object of which is to give such practical directions for the proper construction and management of gas-fittings, as may lead workmen to give the requisite forms and proportions to the parts, and may enable the consumers to obtain the quantity of light they require, from the smallest practicable expenditure of gas, and with the least possible inconvenience from the products of its combustion.

It is very generally believed, by workmen and others, that the more freely the current of air is admitted to an argand burner, the better will be the light; and hence the burners and glass chimneys in ordinary use are made in such a way as to favour this view. No practice, however, can be more incorrect, or can lead to less economical results. An attentive observation of what takes place will show, *that there is only a certain proportion of air required for the favourable combustion of a definite measure of gas.* If more air than this due proportion be allowed to pass up the chimney, the size of the flame will be reduced, and the quantity of light diminished; if, on the other hand, less than the due proportion be admitted, the surface of the flame will be increased by elongation, but it will become obscure, and the quantity of light will decrease, owing to the escape of particles of unconsumed carbon. A simple experiment will exemplify this. If the flame of an ordinary argand burner be reduced, by partially shutting the cock, to about half an inch high, the light will be pale and blue, because the supply of air is too great for the small quantity of gas which is issuing. If partial obstruction be given to the access of air, by applying a handkerchief under the burner and chimney, it will be found that the size of the flame and the quantity of light emitted will increase until it arrive at a maximum, when, by farther obstruction, the admission of air will be reduced below the proportion required for the burning of the carbon, and the light will diminish.

It appears, therefore, that the proportionate size and shape of the burners, and the diameter and height of the glass chimneys, are by no means indifferent matters, but that much advantage may be gained or lost by giving them such forms and proportions *as may insure the development of the maximum degree of light which the gas is capable of affording.*

As a general rule, it may be considered that in all burners, whether well or ill made, the greatest quantity of light, *in proportion to the gas expended*, will always be obtained when the flame has been raised as high as it will go without smoking. In proof of this, the following experiment may be made. In any situation where there are three or four burners of the same size, and with similar chimney-glasses, and receiving their gas through a meter (by which the expenditure may be measured), if one of these burners have its flame elevated as high as it can be made to burn without smoking, and if its expenditure per hour be accurately noted on the meter, if the other two or three burners be then lighted, and their flames be so regulated that their united lighting power shall be just equal to the large flame of the first burner, it will then be found, on noting the expenditure, that it is much greater than in the case of the equal light from the single burner, and that the first burner, which gives light equal to two others, consumes but two-thirds of the gas which they do, or, if it be compared with three others giving together an equal degree of light, its consumption will be little more than half of theirs. It follows from this, that when a certain degree of light is required, such a burner should be employed as *is capable of giving this light and no more*, and that it is bad economy to use a more powerful burner with a flame of less than its due height. This rule holds good with any number of burners, and is equally true whether they be well or ill made.

The same rule will apply to the individual jets of an argand burner, as holds in regard to their united effect, and if, in any burner, the jets be of unequal heights, in consequence of bad drilling of the apertures, or neglect of keeping them free of dirt, the consequence will be, that when the flame is raised until the jet from the widest hole reaches the most advantageous height, those from the obstructed holes will be consuming the gas at a disadvantage, which will be greater or less according to circumstances, but will always be of greater amount than is generally supposed.

The experiments made by Drs. Turner and Christison serve to show, that much smaller chimneys than those usually employed are required to burn the gas to the best advantage. Unfortunately, however, the dimensions most favourable to economy in one respect, are beyond the limits of economy in another; and when the glasses are made small enough in diameter to obtain the maximum of illuminating effect, they are liable to be softened by the heat: or to be cracked, *if not accurately centred.* A compromise between the two evils must therefore be made, and if this be judiciously done, *a great improvement on the usual routine practice may be effected, a more beautiful and steady light be obtained at a less cost, and our domestic comfort be increased, by the diminution of the heat and effluvia of the gas.*

For practical purposes, therefore, the following directions may be observed.

Whatever diameter is given to the burner, the glass chimney should not exceed it by more than half an inch at the utmost. If the burner be less than three fourths of an inch in diameter, the chimney glass should not exceed 1⅛ inch in internal diameter. In any case, its height should be no more than four inches above the mouth of the burner from which the jets spring.

The smallness of the interval which is in this way allowed between the flame and the glass, renders it necessary that the workmanship of the supporting gallery be accurate, *in order that the chimney may be held perpendicular, and truly concentric with the flame.* Gas-fitters rarely give sufficient attention to this important point, and a large share of the expense from broken glasses is owing to defects in this particular.

In the ordinary mountings, the gallery is put on the burner, which it seldom fits accurately, the glass likewise rarely fits tight into the socket of the gallery, and from these two causes, it is often so much off the centre, or so far from being upright, that the flame cannot be raised to a proper height without risk of breaking it. This risk may be greatly diminished by a little change in the disposition of the burner and gallery. Instead of hanging the gallery on the burner, it should be placed beneath it, and fixed by screwing down the burner on it. In this case, it is necessary to give the gallery an increased diameter, as the air, both for the inside and the outside of the flame, must enter through its ribs. The burners should also be made conical instead of cylindrical; but this is not so important as drilling them with numerous holes—at least double the number usually allowed, as the closer they are the better, the expenditure being regulated by the stopcock, and not by the number of holes.

In making the galleries, great attention should be paid to having the rim and seat for the glass truly concentric with the hole through which the nozzle-screw, on which the burner is fixed, passes; the workmen should have a solid wooden chuck of the size of the bells of the chimney-glasses, and should chuck the galleries on it, in order to drill the aperture through which the nozzle-screw is to pass. The outside and inside faces of this hole should at the same time be turned true, as, if this be done with the proper care, the glass, the burner, and the gallery, will all be true to the same axis, when they are put together and screwed up. The hole through the gallery should not be tapped, as the burner is sufficient fixture for it when screwed down over it. If this part of the work be well executed, even an indifferently made burner will perform well, and if it be ill done, the best burner will appear defective, and be liable to break the glasses.

The arrangement of burner and gallery here recommended is not incompatible with the use of plain cylindric glasses, but it will be found better to use what is sometimes called the French-shaped chimneys, that is, those which are used with the common argand oil-lamps. The wideness of their mouths gives them a firm seat in the gallery, and if the length of the bell, or wide portion of the glass, be such that the neck or choke shall be on the level of the lip of the burner, and the upper part of the glass be four inches to four inches and a half long, then a favourable result will be obtained. It is expedient to obscure the lower part or bell of the glass, as the burner is thereby concealed, and the flame appears to rise out of a thick wax-candle. No moon-shades should ever be used, as, besides intercepting a considerable portion of the light, they prevent the consumers from observing whether the burners and glasses be in good order, and performing properly.

It is pretty generally imagined that the smoking of ceilings is occasioned by impurity in the gas, whereas in this case there is no connection between the deposition of soot and the quality of the gas. The evil arises either from the flame being raised so high that some of its forked points give out smoke, or more frequently from a careless mode of lighting. If, when lighting lamps, the stopcock be opened suddenly, and a burst of gas be permitted to escape *before* the match be applied to light it, then a strong puff follows the lighting of each burner, and a cloud of black smoke rises to the ceiling. This, in many houses and shops, is repeated daily, and the inevitable consequence is a blackened ceiling. In some well-regulated houses, the glasses are taken off and wiped every day, and before they are put on again, *the match is applied to the lip of the burner, and the stopcock cautiously opened, so that no more gas escapes than is sufficient to make a ring of blue flame;* the glasses being then put on quite straight, the stopcocks are gently turned, until the flames stand at three inches high. When this is done, few chimney-glasses will be broken, and the ceilings will not be blackened for years.

Gas-fitters and lamp-makers generally put the stopcocks in situations where it is difficut to get at them, and they make their heads so small that, if they be in the least degree stiff, it is not easy to turn them gradually; hence, when a little force is applied, they move by starts, and the flame is sometimes raised too high, or, instead of being a little lowered, is altogether extinguished. The remedy for this inconvenience is to make the cocks easily accessible to a person standing on the floor, and to make their levers so long that their movements may be easily graduated. The cocks and levers may easily be designed so as to form part of the ornamental work of the lamps.

The argand burner being the most perfect and economical which can be used, unless where small portions of light are required, it is unnecessary to say any thing of the bat-wings and other fancy burners, especially as the only precaution to be taken with them, is to take care not to raise them so high as to smoke, and never to use two or more low flames, when the same degree of light can be got from one flame burning at its most effective height.

A mode of supplying argand burners with a current of heated air has been lately proposed in Paris, and much praised in London. This is effected by having an outer glass of a diameter a little larger than the inner one. This outer glass reaches farther down than the bottom of the burner, and is closed below by a metal plate; the air for the supply of the flame is made to pass down between the outer and inner glasses, where it gets heated: it then enters the inner glass and the centre aperture of the burner, and passing upwards, supports the combustion of the gas in the usual way. There is no doubt that, by this arrangement, a considerable improvement may be made in cases where ill-made burners, with wide and tall chimney-glasses are employed; but if the experiment be tried with burners and glasses proportioned in the way recommended above, it will be found that no advantage is gained, and that the maximum effect has been attained by a simpler apparatus.

Before quitting the subject of burners, it may be right to advert to a frequent cause of disappointment in their performance. The perfection of an argand burner is, *that the flame arising from it should appear in a continuous cylindric sheet, with a smooth upper edge, and without forking points.* This is sometimes very difficult of attainment, however carefully the jet-holes may be gauged by the pricker. There are two causes for this irregularity; one is, that, if the drill which is used be blunt, a little blaze is pushed aside by it when it is forced through the plate in which the jet holes are pierced; this blaze adheres to the edges of the hole, and interferes with the passage of the gas, and being unequal in its effects, renders the flame forked. The other cause is, that the inside of the burner is seldom turned true, and that the shoulder in which the pierced disk rests, is not of equal width all round, and sometimes may be so thick in some places, that the drill, when it gets through the disk, strikes against the shoulder; this likewise interferes with the issue of the gas. To avoid these causes of irregularity, the following precautions are essential. When the seat for the disk is turned out, the inside space between the inner and outer walls of the burner should be turned true for a quarter of an inch inwards, and no more shoulder should be left than just enough to support the disk in its place. The disk should then be put into its seat, but not finally fixed. The requisite number of holes should then be drilled in it, and slightly counter-sunk to take off the burb. The disk should then be reversed (that is to say, the counter-sunk face should be put inwards), and finally fixed in its place. The blaze which may have been pushed through with the drill will now be on the outside, and may be easily removed by the file, or by a slight counter-sinking, which is the preferable manner, as the smooth-edged holes will keep longer clean than those with a sharp arras, the application of an old tooth-brush being sufficient to keep them in good order.

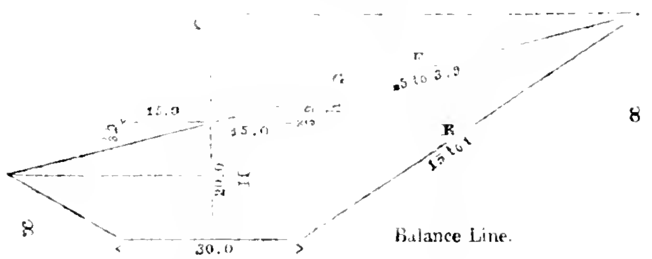
The above observations apply chiefly to the illumination of the interiors of buildings, and it may be proper to notice the circumstances which require to be attended to in lights which, being placed externally, are in some degree exposed to the weather. The most important of these are the street lamps. These may either be arranged at considerable distances, and be fitted with powerful burners, or the intervals between them may be smaller, and only a single jet be allowed for each. Various local considerations must determine this, as well as some other points: but it should be kept in mind, that the best small light is either the single jet of three inches and a half or four inches high, or the fish-tail jet of three inches high, and that for more powerful lights *the argand is preferable to all others*. The large bat-wing, so much used in large public lamps, is wasteful, smokes the lantern, and does not give light in proportion to its expenditure.

In most towns, framed square lanterns are used for street lamps, as it is said that globes are apt to be obscured in cold weather by the deposition of the water generated by the combustion of the gas. It is no doubt true, that if proper precautions be not taken, this inconvenience would be felt, and the water which would trickle from the aperture in the bottom of the globe would be liable to freeze in severe weather, and so to close up the access for air, that the lamp would smoke or go out. In all other respects, globes have undeniable advantages over framed lanterns, as they protect the flames better in high winds, and they are kept up at much less expense.

Some years ago I pointed out to the commissioners of police of this city, that advantage might be taken of the acknowledged good properties of the globes for lighting the streets, and the alleged defect be obviated by constructing the tin tops with chimneys which should reach down to the points of the flames, and by their current carry off the water while still in a state of vapour, and so prevent it from being condensed on the sides of the globes. This plan was immediately tried, and having been found successful, was adopted in all the lamps erected subsequently. It occasionally happens, that from the jet being deranged, the gas is directed past the tin chimney instead of into it, and if the weather be cold, it is immediately observed that a deposition of water takes place inside the globe, and its sides become dim. The adjustment of the burner restores the proper action, and the globe remains bright. This plan having now stood the test of many years experience, may safely be recommended for adoption wherever new street lamps are erected.

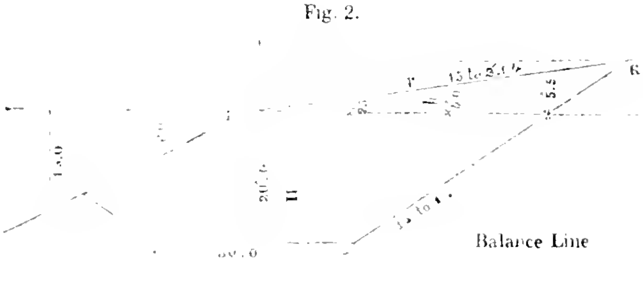
ON SETTING OUT RAILWAYS ON SIDELONG GROUND.

Fig. 1—Sidelong Ground.



C, centre line. G. surface of ground.

Fig. 2.



Sir—Should the following formulæ for setting out widths of railway land on sidelong ground be new, and in your opinion worth insertion, please to give them a place in your next number.

Suppose the centre line of way staked out and pegs driven into the ground at every chain's length, and further that levels have been taken at each of these lengths, both at the pegs and (in the case of a 30 feet base) at 15 feet horizontal distance on each side.

Then putting r for the rate of inclination of ground to a 15 feet length, R for the rate of inclination of slopes to a 15 feet length, H for height of balance line below or above surface at centre stake, h for difference of level between ground at centre peg, and at 15 feet on either side horizontal distance, and x for the actual height above or below balance line, at which the slopes run out to the surface.

We have $\frac{r}{R} x + H + h = x$ or $(H + h) R = R x - r x$ or the height above the balance line, at which the slope cuts out on the higher side.—1.

$\frac{r}{R} x + h + x = H$ or $H R - h R = r x + R x$, or the height above the balance line, at which the slope cuts out on the lower side.—2.

For example, in the case of a 20 feet cutting with base 30 feet, slopes 1½ to 1, and the surface of the ground varying in level from 3·9 feet above the centre peg,* at 15 feet on one side to 3·9 feet below at the same distance on the other side.

By formula 1, $(20 + 3{\cdot}9)\ 10 = 10\ x - 3{\cdot}9\ x$.

$239{\cdot}0 = 6{\cdot}1\ x$.

$39{\cdot}2 = x$ at 1½ 1 $= 58{\cdot}8, + 15 = 73{\cdot}8$.

73·8 horizontal distance to be set off from centre stake on higher side.

Again, by No. 2, $\overline{20 \times 10} - \overline{3{\cdot}9 \times 10} = 3{\cdot}9\ x - 10\ x$.

$161{\cdot} \quad = 13{\cdot}9\ x$.

$11{\cdot}5 \quad = x$.

At 1½ to 1 $= 17{\cdot}2 + 15 = 32{\cdot}25$ horizontal distance to be set off from centre stake on lower side.

It is here understood that these calculations are made in the evening after return from levelling, the depths of cuttings or embankments obtained by reference to a section run before hand over the centre line of way, and that the results of widths are pegged out on the following morning.

Another example is here added, in which the ground is shown as very irregular, although few instances occur to such an extent unless perhaps in Cornwall, &c. The depth of cutting and slopes with base same as before; levels supposed to be taken at A B C D on one side, and at E and F on the other. The extent of levels necessary must be left to the judgment of the party acting.

B 2·7	E = 8·
C 4·	F = 15·
D 5·5	
12·2 levels above A.	23· levels below A.

It is clear that in order to equalize the inclination of the surface, we must obtain a figure forming an arithmetical progression, in three terms to the amount of the higher side levels, but in two terms only to that of the lower.

Take 12·2 as before, of which 2·04 is the number required for the higher side inclination, and 23 of which 7·7 is the figure for the lower. Then according to our previous formulæ—

1. $(20 + 2{\cdot}04)\ 10 = 10\ x - 2{\cdot}04\ x$.

$220{\cdot}4 = 7{\cdot}96\ x$.

$27{\cdot}69 = x$ at 1½ to $1 - 41{\cdot}53 + 15 = 56{\cdot}53$.

56·53 to be set off as the horizontal distance from centre peg on higher side, correct ·9 of a foot.

Again No. 2. $\overline{20 \times 10} - \overline{7{\cdot}7 \times 10} = 7{\cdot}7\ x + 10\ x$.

$123{\cdot} \quad = 17{\cdot}7\ x$.

$6{\cdot}95 \quad = x$ at 1½ to $1 = 10{\cdot}42, + 15$.

$= 25{\cdot}42$ to be set off as the horizontal distance from centre peg for lower side.

I remain, your obedient servant,

Geo. B. W. Jackson.

Radcliffe Terrace, Goswell Road,
April 27, 1841.

* The centre peg in this case supposed to be level with ground.

Stone Cutting Machine.—The *Alsace* (Strazburg) states that a native of that town, named Muller, has invented a simple and cheap machine, set in motion by the force of a single dog, turning like a horse in a mill, whereby a stone in its roughest state is in five minutes cut into a regular shape fit for building, and its faces have an unusual smoothness. This machine is capable of working twelve stones in an hour, or 144 in a day of twelve hours, being equal to the labour of forty men employed for the same time. Muller (adds the journal) possesses several quarries of stone, both hard and soft, and works his mill daily in the presence of numerous spectators.

IMPROVEMENTS IN RAILWAYS AND THE WHEELS OF LOCOMOTIVE ENGINES AND CARRIAGES.

In the first place, the leading and trailing wheels of locomotive engines either with four or six wheels would work better were each wheel to be keyed upon a separate shaft, so as to revolve independently.* This may easily be done in the following manner: let the wheels be keyed upon their respective shafts in the usual way, with either outside or inside bearings, which ever may be the most convenient, and let the shafts have middle bearings to meet in the regulating line common to all. If the wheels and axles are made in this way, the wheels on the outside rail would revolve quicker than those on the inside, and would allow the engine to find its own bearings. This would be particularly evident in going round curves, and would be the means of preventing many accidents from engines being very liable to be thrown off the rails on those parts according to the present system. In the second place, it is proposed that each of the leading and trailing wheels shall be keyed upon a hollow shaft, in the usual way; these shafts to have no external bearings, but to be bushed with brass bored to fit the solid shaft, or spindles which will be required to work into them. The solid shafts to have a bearing at each end, and one in the middle if required. This plan will allow the outside and inside wheels to revolve independently on the curves or otherwise, and will also prevent them wearing irregularly. Should any obstacle be thrown in the way of the engine, the wheels revolving separately would prevent it from coming off the rails, as the wheels would act as a check to each other, or as a complete check or guard rail on any part of the line as hereafter explained.

Thirdly. The wheels to be made of either wrought or cast iron, (the latter would be preferable,) and to have a flange on each side, by which plan they would not be required so strong as those now in use, because they would take the lateral concussions or side jolts more equally than the present kind. Should the engine be thrown to one side, both wheels would take an equal share of the strain or jolt, whereas in the present system the wheels on one side take the whole strain. This properly adjusted, the conical wheels may be dispensed with, as well as the check or guide rails upon the whole line, which latter checks are a great nuisance. In the plan thus proposed the rails would be laid level or horizontally across and not at an angle as at present, and the wheels would have to be the segment of a circle† upon the face, in place of being conical. Each wheel would thus act as a check rail for the other during the whole of the journey. Should the rails be out of gauge so as to cause the wheels on one side of the engine to mount upon their flanges, and throw the train off the rails, as is very often the case with the present system, the double flanges would obviate this evil and keep the engine in its proper course, until the wheels again found their places. The switches will remain without alteration, but the points may be altogether dispensed with. By this method of working, there will be a great saving in the wear and tear of the engines and rails, it will reduce the cost of keeping the engines and road in repair, and lessen the friction, as well as the quantity of fuel with all other expenses in like proportion. In constructing the permanent way much time might be saved, as no attention will be required in laying the rails to an angle, as they would then be horizontal where the road itself is straight. Giving to the outside rails the proper rise in the curves, the angle of the two rails will incline both one way, and not reverse to each other as at present. This will afford the engine another mechanical advantage on the curves, giving gravity a much greater opportunity of acting against the momentum of the machine. The engine will also be kept in its proper course in the curves much more forcibly than is afforded by the present method of laying railroads by the present system, as the angles of the two rails are acting against each other, the outsides of both being higher than the insides, and causing a great friction upon the axles, brasses, wheels, and rails; this the proposed alteration will entirely obviate. All the conical wheels now in use, through concussions and constant rolling upon the rails, squeeze out on one side. No conical wheels retain their proper form much longer than two months if daily at work: each wheel causes the flange of the opposite wheel to act with great force on the inside of the rail, and *vice versa*. The large hollow inlet that is left in the angle of the flanges of the wheels crushes down the inside angle or corner of the rails; which the proposed wheels would obviate—the weight of the vehicle would be also much better distributed over the surface of the rails. This alone is a great inducement to the introduction of double flanged wheels on loose axles, as the rails would last double the length of time.

In the fourth place, the double flanges would prevent the wheels squeezing out, as they seldom squeeze out on the side next the flange, and being all made from cast iron, there would be no spreading. The longitudinal shake or clearance that is generally given to the axles in their brasses will not be required, as the action of each being entirely in itself, and inclosed in brass, will retain the oil much longer and not require that attention which the present do. Were the engines and carriages made according to this arrangement the loss of power in the curves would not exceed from 8 to 10 per cent. above that used on a straight line, always of course depending on the radius of the curves.

In the fifth place, the whole of the engine and tender wheels should be furnished with double flanges, the latter to be of different diameters; causing thus different depths from the face of the wheel to the tops of those flanges. The reason of this will be easily explained.

Railways at present are nothing but a series of complication of curves, all differing in intensity. To carry engines round those continually changing curves without trailing and great friction, would require wheels of greater and less diameters, and this difficulty I propose to surmount by means of those flanges, which will become *bona fide* for the time the wheels of the machine.

To enable me to make use of the above arrangements, I propose to have radiated plates or segments put down on each side of the main rail, at such a depth from the face of the rail, as to cause the wheels to be lifted from the rail, and allow the flanges to act on those segments; the machine rolling at one time on the large flange, at another time on the small, and from thence on the face of the wheel, those alternations of course depending on the nature and radius of the curve. The length and position of those segments would be found by a calculation depending on the intensity of the curves.

Were engines, carriages, &c., provided with such wheels, and the railways with segments to suit, it would be next to impossible for the train to leave the line of road; for, even supposing the whole of the tires on one side were to come off, the train would be kept in its course by the double flanges of the wheels on the opposite side. At present if a single tire comes off, the engine is precipitated from the rails, and if without any more serious result, the train is detained till the arrival of another engine, train, or other means of locomotion.

I may in addition mention that the fatal accidents arising from furious driving which is more or less practised on all lines, and is a terror to all travellers who have not the iron nerves of his Grace the Duke, would be altogether prevented; for not even the velocity of 100 miles per hour could force the engine or carriages off the line, so firmly would the wheels be bound to the rails, and so sweetly would they glide round the curves if made on the above construction.

With many apologies for intruding my ideas on your acquaintance,

I am, your obedient servant,

WILLIAM ANDREWS.

Paddington, March 26, 1841.

P.S. Were the wheels and segments calculated for each other, the parting or cutting of the shafts could be dispensed with, and they might remain just as they are at present.

W. A.

* Our correspondent will find that Mr Coles has anticipated him, if he refers to the Journal for April last, where he will see a method of making the wheels revolve independently of each other.—Ed.

† Wheels with concave rims were used on the Penrhyn Iron Railway. See Repertory of Arts, &c., for 1803, page 285.—Ed.

MR. MUSHET'S PAPERS ON IRON AND STEEL.—No. 2.

Sir—It is my intention in this letter to make a few remarks on the latter part of the paragraph in Dr. Ure's dictionary alluded to in my former letter) in which he says "the incorrectness of Mushet's statement becomes most manifest when we see the white lamellar cast iron melted in a crucible lined with charcoal take no increase of weight, while the gray cast iron, treated in the same manner, becomes considerably heavier."

This remark is as inapplicable to my table of proportions as the remark made in the former part of the paragraph. My experiments were confined solely to the changes produced in the character of iron by the fusion, not of cast iron, but of bar or malleable iron in contact with certain quantities of charcoal.

I have no where professed to account for the reason why that while white cast iron when fused alone with charcoal does not increase in weight, gray cast iron does, nor have I any where either asserted or denied that the fact is as stated by Dr. Ure, and I cannot help thinking that it is unfair in that gentleman, to raise up objections which have no foundation except in his own imagination, in order to throw them at what he calls my statement.

In my former letter the difficulty of obtaining an increase of weight in fusing cast iron alone with charcoal, is accounted for by the great fusibility of that kind of iron which, before the high temperature necessary for the exertion of the greatest force of affinity, can be raised upon it as a solid, occasions it to pass into the fluid state, in which no union can take place between it and the carbon.

The table of proportions, as has been already observed, is a simple recapitulation of the results of the fusion of bar iron with given quantities of charcoal to exhibit the various states and qualities of cast iron and cast steel. By these results it appears that less charcoal is required to form white cast iron than to constitute gray cast iron, and, after forty years' observation and experience this is still my decided opinion. Dr. Ure on the contrary thinks that common white pig iron contains a maximum dose of carbon and that the grayest pig iron of the blast furnace contains less. Hence it may be inferred (according to the reasoning of Dr. Ure,) that white cast iron when fused with charcoal, does *not* increase in weight, because it is already so saturated with carbon as to be unable to take up any more, and that gray cast iron, when fused in the same way, *does* increase in weight, because it contains a comparatively small quantity of carbon, and can therefore absorb an extra dose in its fusion with charcoal; but in what quantity this absorption takes place, or to what extent, the reader is left to guess.

Dr. Ure, following Karsten, says that white pig iron contains from 4½ to 5¼ per cent. of carbon, and gray iron from 3½ to 4 per cent., but the gray iron may, according to Dr. Ure, be considerably increased in weight by its fusion with charcoal. If we suppose this increase of weight to be from 2 to 2½ per cent. (from experiment I know it may be more), then we shall have, for the quantity of carbon in gray cast iron, the original quantity, from 3½ to 4 per cent., and the experimental quantity from 2 to 2½ per cent., making from 5½ to 6½ per cent. a proportion exceeding the maximum quantity assigned by Dr. Ure to white cast iron.

The following remarks will throw a little light upon the subject, and enable us to explain the phenomena without having recourse either to the theory of Drs. Ure and Karsten, or to the expedient of impugning the accuracy of the table of proportions.

Were white pig iron of a definite character, manufactured under the same cinder and circumstances in the blast furnace, and found to contain at all times the same quantity of carbon, it might be possible to arrive at some certain conclusion as to the results to be obtained by its fusion with charcoal. But if we consider that the white cast iron, particularly of this country, is generally made accompanied by a black or blackish brown cinder, containing portions of unreduced iron, it will be obvious that we have to deal with an impure and imperfect state of the metal, varying in quality as the proportions of carbon, oxide of iron, or earthy matter be absent or predominant. Hence the great difficulty of stating any thing definite on the subject, or of arriving at any satisfactory result, as we may use many different sorts of white pig iron, more or less pure, and containing more or less carbon to deal with.

By those who, like myself, have entered largely into this field of investigation, white cast iron has been estimated to contain from 1½ to 2 per cent. of carbon, (and not from 4½ to 5¼ per cent., as Dr. Ure has it,) together with a fraction of the unreduced ore and its accompanying earthy parts in combination with the iron, even when its fracture appears to be the most dense. The existence of these impurities is made most obvious in fusing white and gray cast iron in crucibles, and observing their molten surfaces respectively. The white iron, according to the degree of its impurity, presents upon its surface a quantity of slaggy matter, varying from ½ to 2 per cent. on the weight of the iron, while, under similar circumstances as to fusion, the gray cast iron exhibits a pure convex surface without a trace of slag.

Again in the cementation of white cast iron by heating it in contact with charcoal, with a view to convert it into gray iron, should the process be interrupted after a few hours' exposure, the surface of the iron will be found covered with minute hemispheres of slag of various diameters (but none of them exceeding half a tenth of an inch), opaque, containing iron, and easily displaced. At a more advanced stage of the cementation, the hemispheres of slag will be found to have parted with their iron, to have become more brittle and transparent, and to cover small globules of iron which (as evidence of the reduction of the metallic oxide united to the iron before alluded to) have inserted themselves on the surface of the bar. When white cast iron with a polished surface is used in a similar experiment, the hemispheres of slag and globules of iron do not make their appearance, but oozings take place which form themselves into highly magnetic matters with a specular surface, adhering partly to the iron and partly found in the charcoal, from whence they are easily withdrawn by means of a magnet.

It seems obvious from these facts, that a portion of weight may be thus lost (namely the oxygen of the oxide and the glass which has been disentangled from the metal by a process of incessant reduction), sufficient to account for white or lamellar pig iron, or some sorts of it, not increasing in weight when fused in contact with charcoal, in as much as the sum by weight of the oxygen, an unreduced but separated oxide and earth, may equal, or amount to more than, the carbon absorbed during the operation, and make it appear not only that no increase takes place, but that actual loss is sustained without calling into question the disposition which white cast iron may have to absorb or repel carbon in its fusion with charcoal.

Were it possible to obtain white cast iron as free from oxide and earthy matter as gray iron, and were it to be found on experiment that such iron gains no weight by its fusion with charcoal, while gray iron does, I should be inclined in some measure to account for this (as in my former letter) by the early fusibility of the metal, and from its being a more rapid conductor of heat than gray iron, which causes it to enter into fusion before an absorbing affinity can be instituted between it and the charcoal, while the latter, being a worse conductor, remains longer as a solid in a high temperature to absorb the carbon. Some sorts of white cast iron pass into gray iron in the crucible with facility, but not with any material augmentation of weight, the oxygen, oxide, and earthy matters lost being equivalent to the carbon gained. In other white pig iron I have experienced a decided increase of weight, while its fracture remained apparently unaltered, but more frequently when the white iron was changed to gray.

The same anomalies attach to the scale of manufacture. Different ores tend, according to their constituent parts to produce various qualities of iron as to their degree of carbonization, and some, when smelted alone, uniformly produce white iron.

These various shades of quality all vanish in the crucible through the application and medium of lime, to which is to be added as much argillaceous schist only as will convert the lime into a pure porcelain slag. Fusion under these circumstances, and with $\frac{1}{80}$ the weight of iron of charcoal, will convert the most imperfect white cast iron into the most beautiful carburet, equal in point of saturation of carbon to any thing that can be produced in the reduction of iron ores in the crucible, and superior to any thing that is produced from the blast furnace. Under the most favourable circumstances, the increase of weight in these cases seldom exceeds ½ per cent., while the same experiment made with gray iron would acquire an additional weight of from 2 to 2¾ per cent., clearly indicating the loss which is sustained in the fusion of white iron from the causes before mentioned.

Your's, &c.,

D. Mushet.

Coleford, April 27, 1841.

QUERIES.

Sir—I should feel obliged if you, or any of your numerous correspondents could afford me any information on the subject of the instruments and machinery, which have been at various times invented for the purpose of assisting and facilitating draughtsmen in the correct delineation of existing buildings, under different titles, as the Camera Lucida, Perspective Machine, &c.; many improvements have of late years been made in this department, and it is of these that I wish to obtain information. And I cannot help thinking that it is far from being an unimportant subject to the profession, as it tends greatly to facilitate one great object of travel to the architect, viz., the obtaining of strictly correct delineations of the different structures which may fall under his notice, with the least possible waste of time. In conclusion, I hope that gentlemen may be induced to furnish the names, &c. of any instruments of this description they may have seen, in order that their relative value may be known, as it has often happened in this profession as in others, that inferior and inadequate instruments have been employed merely through ignorance of the existence of better. Hoping that you will pardon my troubling you.

I am, Sir, your humble servant,

Archt. Angl.

Sir—If any of your readers could give me information on the following subject, I should be obliged to them.

How is the permanent way laid on the Greenwich arches? what is the cost of keeping it in repair? what thickness is there of ballasting between the rail and the extrados of the arch at the crown? and what is the cause of the feeling of rigidity, and of the jolting complained of on that line?

How are these points arranged on the Manchester and Birmingham, and other lines, where a railway is carried for a considerable distance on arches?

The comparative advantages of these methods, with any suggestions respecting them, will oblige

Your obedient servant,

May 3, 1841. A. B.

STEAM NAVIGATION IN AMERICA.

Written by Francis Anthony Chevalier de Gerstner, during his sojourn in the United States, in 1839.

[From the *Journal of the Franklin Institute.*]

1. *History and extent of Steam Navigation.*

Fulton, the North American inventor of steam navigation, constructed, in the year 1807, the first steam boat upon the Hudson river, to make regular trips between New York and Albany. The voyage of 145 miles was then performed in 33 hours. The success of this enterprise laid the foundation of steam navigation in the United States.

Up to that time the barks upon the Ohio and Mississipi were propelled partly by sails, partly by oars and poles; from Cincinnati to New Orleans (1600 miles), such a bark came down in five weeks, and went up in 80 to 90 days; for its management nine men were required down, and 24 to 32 up stream. In March, 1811, the first steam boat built by Fulton, in Pittsburgh, called the *New Orleans*, was launched on the Ohio, and commenced in December of the same year, to make regular trips between Natchez and New Orleans. The time required to make the trip of 300 miles between the two places was three days down stream, and seven to eight days up. The boat performed in a year only 13 trips up and down, or 7800 miles. A passenger paid 18 dollars for a passage down, and 25 dollars for one up stream.

Fulton constructed several other steam boats in the United States. He afterwards went to Europe, to bring into execution there, his important invention; but he found no encouragement in England, and when he proposed in Paris the introduction of steam navigation, he was derided by the French, and Napoleon declared him an adventurer. Five years elapsed, before Bell, in 1812, constructed the first steam boat at Glasgow, in Scotland. Steam navigation now came more and more into practice in Europe, but has as yet not attained such an extent there as in the United States, (except England.)

On the 6th of May, 1817, the first steam boat, the *Enterprize*, went up the Mississippi and Ohio, from New Orleans to Louisville, and arrived there on the 30th of May, or in 25 days. As the barks at that time required nearly three months for the same journey, the inhabitants of Louisville were in such an ecstacy, that they conducted the Captain Shrive, around in triumph, and gave him a public dinner. The steam boats upon the western and south-western waters were now constantly increasing in number, and in 1834, they counted already 234; in the year 1838, their number rose to 400. In 1831, there passed through the Louisville and Portland canal, in the State of Kentucky, 406 steam boats, and 421 flat boats, with a tonnage together of 76,323; in the year 1837, passed through the same canal, 1501 steam boats, and only 165 flat boats, with a tonnage together of 242,374.

In the year 1818, the first steam boat was launched on the great north-western lakes; in 1835, they were navigated by 25 steam boats, and in 1838, the number of steam boats was 70. In the year 1834, 88 new steam boats were built in the United States; in 1837, or three years after, 134 new steam boats were launched. The largest ship-yards for building steam-boats, are at New York, Philadelphia, Baltimore; at Louisville, New Albany, Cincinnati, Pittsburgh, and St. Louis.

In total, there were in the summer of 1838, about 800 steam boats in operation in the United States; the greatest number, in any one State, belonging to New York, viz., 140.

The travel in steam boats along the sea-shore has, as I observed in my former letters, been mostly superseded by railroads, located in a more or less parallel direction to the sea coast; and will, probably, when the whole railroad system is completed, entirely cease; but the steam navigation upon the navigable rivers is getting more into practice; its increase in the last two or three years, has contributed much to diminish the navigation with sailing vessels or barks; not only all kinds of merchandise without exception, but also provisions, as grain, flour, meat, &c., are carried in steam boats as well up as down stream, and while the freightage is almost the same as upon the barks and sailing vessels, the goods arrive much sooner at the place of their destination if carried in steam boats, and are, therefore, less liable to be damaged. But still more has been done. Upon the Ohio river, stone coals are now brought by steam boats, 250 miles, down to Cincinnati, or rather the flat boats, loaded with coal, are taken in tow and brought down the river by steam boats, and the empty barks taken back in the same way, because the cost of transportation is found to be less in this manner. It is true, the extremely high wages of the boatmen and all other labourers, contribute much to this extraordinary result; but, as I shall have occasion to show, hereafter, the crew of a steam boat is also very well paid, and it is to be ascribed entirely to the perfection in the construction of vessels and the engines used in them, and in the application of steam, as also to the improved arrangements in the steam boats generally, that they have produced in America the results which have been arrived at neither in England nor in any other part of Europe.

The Americans boast of a system of navigable streams in the southern and south-western states not to be met with in any other country of the globe; they maintain that the length of the Mississippi, with the Ohio and all other tributary streams, comprises an extent of 100,000 miles of water navigable by steam boats. I would not answer for the correctness of this number, but the Mississippi alone is navigated by steam boats from New Orleans, under the thirtieth degree, to the Falls of St. Anthony, under the 45th degree of north latitude, a distance not less than 2000 miles, and the number of navigable tributary streams of the Mississippi is indeed so large, that an European, who is accustomed to our short travels by steam boats, can only, by being an eye witness, conceive the magnitude of the system of steam navigation in this country. There are daily, at least four or five steam boats starting from New Orleans for Pittsburgh, in the business season, and as many arrive daily; the distance is 2000 miles, or two-thirds of that from England to New York across the Atlantic, and nevertheless the voyage is regarded as nothing extraordinary, and is undertaken after a few hours preparation.

2. *Construction of Steam Boats and the Engines used therein.*

The steam boats in America, with the steam engines used in the same, are of three entirely different plans of construction. Those upon the eastern waters, comprising the sea along the coast of Boston to Charleston, S. C., and all rivers emptying into the same, have condensing engines with large upright cylinders, and long strokes, the larger boats draw from five to seven feet water, and go with a speed of from ten to fifteen miles per hour. Upon the Hudson river, the distance from New York to Albany, of 145 miles, is performed in eleven to twelve hours up stream, and in nine to ten hours down stream, including the stoppages at fifteen or twenty landing places, where passengers come on board or leave the boat. I took a passage in the steam boat, *North America*, on the 23rd of November, 1838, from New York for Albany; as the river was already nearly half frozen over, a great deal of floating ice was coming down; the boat left New York at five o'clock in the evening, and arrived at Albany the following morning at seven o'clock; we made, therefore, including all stoppages, over ten miles per hour up stream. The length of the vessel is 200 feet, greatest width 26 feet; she has two decks, the lower of which, where the engines are, is about three feet above the level of the water; she has two separate cabins, the gentlemen's cabin, which is, at the same time, the dining room, and the ladies' cabin. We had 320 passengers on board, each of whom slept in a berth, and as sufficient room appeared still to remain, one may imagine how colossal this floating palace must be. Two steam engines with 52 inch cylinders, move the paddle wheels of 22 feet in diameter. The pressure of the steam of this, as of most of the steam boats upon the eastern waters, is about fifteen pounds per square inch, and the stroke eight to ten feet; the steam is generally cut off at one-third or one-half of the stroke, and operates by expansion. For a voyage of 145 miles, 25 to 30 cords (of 128 cubic feet) of soft wood are required. The *North America* draws, when loaded, six feet; but there are passenger boats upon other rivers in the east which draw, when loaded, only 24 to 30 inches of water, and move against strong currents.

The steam boats in the west, or upon the "western waters," are, throughout, very flat, and go, when loaded, generally five feet deep, some, however, only thirty to thirty-six inches. When the water in a river is only thirty inches deep, the steam-boat contains only the engine and fuel, and the cabins for the men, and flat boats loaded with goods are taken in tow. The passenger boats have two decks, the upper one is for the cabin passengers. The elegant boats contain a large splendidly furnished and ornamental saloon, used as the dining-room, and an adjoining saloon for ladies. The saloons are surrounded by small apartments, (state rooms), each of which contains two berths, and round the state rooms is an open gallery, to which a door opens from each state room. Such a vessel offers to an European an imposing and entirely novel aspect. All steam-boats upon the western waters have high pressure engines, the pressure of steam being from 60 to 100 pounds per square inch. Often two engines are used in a boat, and then each engine propels one of the paddle-wheels. The cylinders are horizontal, the stroke is eight to ten feet, and the steam is generally cut off at five-eighths of the stroke, and then operates by expansion. The escaping steam is applied to heat the water pumped from the river, before it gets into the boiler.

The third kind of steam-boats is to be found upon the lakes in the north and north-west of the Union, they generally go much deeper than the former, are more strongly built, and are propelled partly by condensing and partly by high pressure steam-engines.

3. *Progress of Steam Navigation since its introduction in the United States*

The perfection attained in steam navigation may be estimated after a comparison of the former and present performances of steam-boats, and of the former and present rates of charges for transportation of passengers and merchandise.

In the year 1818, a cabin passenger paid for a passage in a steam-boat from New Orleans to Louisville, a distance of 1450 miles, 120 dollars, and for returning, 70 dollars, the passages up took twenty days, and down, ten days; at present, cabin passengers pay, in the most elegant steam-boats, 50 dollars for a passage up, and 40 dollars for one down stream; while they go up in six, and down in four days. These charges include boarding, which, considering the abundance and choice of the victuals, &c., ought to be estimated at two dollars per passenger per day. The fare is, therefore, now, for the passage alone, taking the average between a trip up and down, (excluding board), 2·41 cents per mile. Less elegant boats take cabin passengers up in eight days, for 30 dollars, and for 25 dollars down in five days, which, after deducting one and a half dollars per day for board, gives only 1·22 per mile, at an average between a trip up and down.

Upon the lower deck of these steam-boats, which is a few feet above the surface of the water, are the deck passengers, who provide their own meals, and pay for the same passage of 1450 miles, only eight dollars; if they assist

2 E 2

the crew [illegible] engaging [illegible] on the boat, they pay only five dollars. [illegible] former [illegible] they pay, [illegible] per mile, [illegible] cents.

Merchandize was carried, before the introduction of steam navigation, in sailing vessels, which took a load of 150 tons; in the year 1817, the charge for freight per pound, from New Orleans to Louisville, was seven to eight cents; in 1819, the steam-boats commenced carrying freight, and immediately reduced the charge to four cents per pound. At present, the charges per one hundred-weight, from New Orleans to Louisville, are according to the quality of the goods and the season, at least 33 cents, and at the most, one and a half dollars; at an average they may be taken at 6[illegible] cents for the distance of 1150 miles. This makes 0·6 cents per ton per mile.

Between Cincinnati and Louisville, the first steam-boat, *General Pike*, was put in operation in 1819, and made, weekly, a voyage down to Louisville, 150 miles, in eighteen hours, and up again to Cincinnati in forty hours. A cabin passenger paid at that time twelve dollars for a passage. At present, the steam-boats have so much increased in number, that at least six boats are daily starting from and arriving at Cincinnati or Louisville. Upon the finest boats, as, for instance, the *Pike* and *Franklin*, the fare is four dollars, and the time occupied in going up is, including all stoppages, fifteen hours, and in going down only eleven hours; but these boats have frequently made a passage up in twelve, and a passage down the river in seven and a quarter hours; in the latter case the speed was therefore over twenty miles per hour. If one dollar be deducted for board, there remain three dollars for the passage, which is at the rate of two cents per mile. The deck passengers who assist in taking in wood, pay only one dollar, or two thirds of a cent per mile and find their own victuals. For merchandize, the charges are fifteen cents per cwt., or two cents per ton per mile.

From Cincinnati to St. Louis, the voyage is 538 miles down the Ohio, and 192 miles up the Mississipi river, making together 730 miles. The passage to St. Louis, or from there back, is performed in four days. A cabin passenger pays twelve dollars, of which we ought to deduct at least four dollars and seventy cents for board, this leaves only one cent per mile for the passage only. The deck passengers pay four dollars without board, which makes nearly one half cent per mile. Goods pay, at an average, 50 cents per one hundred weight, 1·37 cents per ton per mile.

Upon the Hudson river, the passage fare is, in the most elegant boats, three dollars for the distance of 115 miles between New York and Albany, which gives two cents per passenger per mile; for meals an extra charge is made. In less elegant steam boats, passengers are carried the same distance for one dollar, and at this moment even for 50 cents, which gives only one-third of a cent per mile.

From the above data we may infer that, at an average, cabin passengers upon the American rivers pay according to the elegance of the steam boats, from two and a half cents down to one cent per mile (board not included), and deck passengers only about one half cent per mile; both travel, taking the average between up and down stream, with a speed of 12 miles per hour. Goods upon the same steam boats are carried, at an average, for one and one-third cents per ton per mile.

These striking results, which are attained nowhere else, are chiefly derived from the improvements constantly made in the construction of the boats and their engines. Of the 800 steam boats at present navigating the American waters, hardly two will be found of an entirely similar construction; the steam engines, though subject to the same principles of steam power, differ from the English in nearly all their parts. But three years ago, eight days were required for a trip from New Orleans to Louisville, which is now regularly performed in six. The most remarkable result is, that a boat of 400 tons required, 20 years ago, for this voyage of 1150 miles, 360 cords of wood, while at present, for a six days passage only, the same quantity of wood is required.

4. *Rise of Wages, and of the Prices of all Requisites for Steam Boats during the last year.*

What appears most striking, is, that while the charges for transportation have been constantly reduced during 20 years, wages and the prices of all commodities rose from year to year. The captain of a steam boat received 20 years ago, a salary of 1000 dollars per year, now he gets, upon the better boats, 2000 dollars. Every steam boat has two pilots, who change every four hours; each of them received, in 1822, only 60 dollars a month, but since that time their salary has risen, and was, in 1833, 300 dollars, which is still now paid to the pilots of the best boats; there are also two engineers upon each steam boat, their salary was, in 1822, only 40 dollars per month, and rose in consequence of the great demand for engineers, to 100 and 150 dollars. The firemen and common labourers received, 20 years ago, only 11 dollars per month, and get now 30 to 40 dollars. The whole crew, besides, have free board upon the steam boats.

The provisions necessary for the nourishment of the passengers upon the steam boats, have risen in price during the last five years, 33 per cent.

The steam boats upon the western waters use, almost exclusively, wood as fuel for the engines, which, 20 years ago, was quite valueless; in 1834, it sold on the Ohio and Mississippi, for $1\frac{3}{4}$ to 2 dollars per cord, and costs at present $2\frac{1}{2}$ to $3\frac{1}{2}$ dollars; the price has therefore increased in the last five years, about 50 per cent.

5. *Cost of Steam Boats.*

The steam boats upon the western waters, whose plan of construction might be adopted to great advantage upon our rivers in Europe, are, as I observed already, principally constructed in Louisville, Cincinnati, and Pittsburgh. In general, the hull of the vessel is built by ship carpenters, the steam engine delivered from a manufactory, and put on the boat, after which the joiners build the cabins and finish the whole. Three different classes of mechanics are therefore required, with whom separate contracts are made; there are, however, individuals who undertake the building and furnishing of a whole steamer by contract. As the prices differ much according to the solidity and elegance of the vessels, I herewith state the cost of some of the steam boats, which are among the best.

Between Cincinnati and Louisville, the two steam boats, the *Pike* and *Franklin*, make regular trips, carrying the United States mail; one of the two goes daily up, the other down, the river. The *Franklin* is 183 feet in length at her deck, and the extreme width is 25 feet, the depth of hold, or the distance from the keel to lower deck, is $6\frac{1}{2}$ feet. The tonnage 200 tons. Upon the upper deck are 42 state rooms, each with two berths, making, in all, 84 berths; but mattrasses are laid upon the floor of the dining room, when required, and 150 cabin passengers may sleep upon the boat. The boat is propelled by two engines, the pressure of steam is *eighty pounds per square inch*, the diameter of the cylinders, which are in a horizontal position, is $25\frac{1}{2}$ inches, the stroke seven feet. The steam is cut off at $\frac{1}{3}$ of the stroke, and acts through the remaining $\frac{2}{3}$ by expansion. The diameter of the paddle wheels is 22 feet, their width 11 feet, the dip is 22 inches, the paddle wheels generally make 28 revolutions in a minute. The length of the connecting rod is 23 feet. There are six boilers of wrought iron on board the boat, each 23 feet in length, and 40 inches in diameter, each boiler has two flues of 15 inches diameter.

At an average, the steam boat carries 125 passengers, one half in the cabins, and the other half on deck, and besides 25 tons of goods. With this load she draws six feet water. The boat was constructed in the year 1836, and the cost was :—

	Dollars.
For the hull, at twenty-five dollars per ton........	5,000
— two steam engines	12,000
— joiners' work for cabins	4,000
— draperies, mirrors, bedding, and other furniture in the state rooms, saloons and kitchen	9,000
Total	30,000

This boat is, as observed, one of the most solid and elegant; other steam boats of the same dimensions have cost 5600 dollars less.

Amongst the steam boats of the largest class, which run only between New Orleans and Louisville, the *Sultana* and the *Ambassador*, are now much favoured by the public; the *Ambassador* has 215 feet length of deck, and 35 feet extreme breadth. Her tonnage is 450. On the upper deck are 44 state rooms, each with two berths, but as many beds may be arranged upon the floors of the saloons. Of the two steam engines, each has a horizontal cylinder of 25 inches diameter and eight feet stroke; the steam acts with a pressure of *ninety pounds per square inch*, and is cut off at $\frac{1}{3}$ of the stroke. The diameter of the paddle wheels is 22 feet, their width 12 feet. The boat generally carries 200 tons of goods up, and 300 tons down stream, besides 100 cabin and 150 deck passengers; she draws, empty, five feet, and when loaded, seven feet water. The hull of this boat has cost 12,000 dollars, the engines 17,000, the joiners' work, and the whole inner arrangement of this highly elegant structure, amounted to 31,000 dollars, making the cost of the whole boat 60,000 dollars. It must, however, be observed that great and costly alterations were made during the construction, so that her cost would actually not exceed 55,000 dollars.

Well instructed individuals, who are very much interested in the subject of steam navigation, estimate the average cost of a steam boat upon the eastern waters, at 45,000 to 50,000 dollars, upon the western waters, after a special calculation, at 23,500 dollars, and upon the lakes, the average between the two, or at 35,000 dollars. Consequently all the steam boats, which were in operation in 1838, have cost as follows, viz.

				dollars.
351	boats upon the eastern waters, at	....	47,500	16,672,500
385	ditto	western....................	23,500	9,047,500
64	ditto	lakes,.....................	35,000	2,240,000
800	steam boats, each at an average cost of	....	34,950	27,960,000

Now, as since the introduction of steam navigation, 1,300 steam boats were built in the United States; the whole capital invested by the Americans in steam boats, amounts to 45,135,000 dollars, the greater portion of which has been expended in the last five years.

(To be continued.)

New Motive Power for River Navigation.—A Brussels paper announces the arrival in that city of Dr. Beck, the inventor of the plan for navigating the most rapid rivers against the stream by means of a motive power that is represented to be without limits in its operation, and in which he uses neither steam nor wind power, nor hauling from the banks. It is stated that M. Wagner, of Franckfort, the inventor of the application of electro magnetic power to navigate boats, &c., Dr. Brttger, president of the Physical Society of Franckfort, M. Pauli, the first royal engineer of Bavaria, and many other distinguished scientific men, have proved by experiment the great advantages of this important invention.

ON WARMING BUILDINGS WITH HOT WATER.

An Answer to Messrs. J. Davies and G. V. Ryder's Report on Perkins' System of Warming Buildings by Hot Water. (See the Journal for April last, page 137.) By A. M. Perkins.

The excitement that has been occasioned by the destruction of Messrs. Craft and Stell's premises in Manchester, by fire, arising from the bursting of the furnace-coil of a hot water apparatus, on "Perkins' system of warming buildings by means of hot water," and the measures taken in consequence by the Manchester Assurance Company, have created an alarm as to the general safety of his plan, which the patentee feels it incumbent upon him to show is unfounded, and to prove that whenever accident has occurred, it may in every case be traced, either to the improper construction of the apparatus in the first instance, or to carelessness and mismanagement in the use of it. It appears by a report which has been extensively circulated by the Manchester Assurance Company, that a committee of the Directors of that company was appointed "to inquire into the nature of the accidents which have recently occurred from the use of hot water apparatuses, and to report thereon;" in pursuance of which resolution Mr. John Davies and Mr. George Vardon Ryder were directed "to institute a personal investigation into some of the cases referred to, and to make such experiments as might tend to satisfy their minds as to the causes of the accidents which had occurred."

In the report presented by these gentlemen to the directors, they commence by describing "the appearances observed" at some of the places which they visited. These appearances consisted of "wood, matting, and cushions, in a variety of places contiguous to the hot water pipes, having been charred to an alarming extent," and that Mr. Barbour's warehouse had "been on fire, *close to the pipes*, at different times and in different places." The Unitarian Chapel in Strangeways, also showed marked "appearances," the floor being charred black, and at the Natural History Museum in Peter Street, the matting on the floor had been charred, and the floor itself appears to have been scorched. The whole of these appearances were produced by one and the same cause—the overheating of the pipes; and this was doubtless occasioned by the disproportion of the furnace-grate and draught to the furnace-coil, like that erected upon Mr. Walker's own premises, for the purpose of Messrs. Davies and Ryder's experiments. Mr. Rawthorne's communication respecting the Strangeways Chapel affords sufficient evidence of an ill-proportion and ill-constructed apparatus, the deficiency of heat, great consumption of fuel, offensive scent, and charred wood, are convincing proofs that the quantity of tubing laid down in the chapel was insufficient to afford a proper supply of warmth; and the endeavour to procure more heat by extra firing sufficiently accounts for the great consumption of fuel, and the offensive scent given out by the pipes when thus overheated. In an apparatus justly proportioned, the water circulating in the pipes can receive but a given quantity of heat, and any fuel added beyond that point would not cause them to become overheated. It is necessary here to describe what "Perkins' system of warming" really is; for the patentee utterly disclaims the apparatus experimented upon by Messrs. Davies and Ryder as his, any further than that the pipes were closed in all parts.

Perkins' apparatus, then, consists of a continuous or endless tube, closed in all parts, a portion of which is coiled and placed within a *duly proportioned* furnace: from this coil the rest of the apparatus receives its heat by the circulation of the hot water flowing from its upper part, and which, cooling in its progress through the building, returns into the lowest part of the coil to be reheated. The expansion of the water, when heated, is fully provided for by the expansion tube, which is of three inches diameter, and of sufficient length to afford an expansion space of from fifteen to twenty per cent; this, long practice has proved, is ample for the greatest heat which can be attained by the water, as it expands only five per cent. from 40°, its point of greatest density, to 212°, the boiling point. This tube is placed at the highest part of the apparatus, and is empty when the water is cold; the furnace is provided with a damper, by which the fire may be regulated at pleasure. In a well managed apparatus this damper is in general nearly closed after the fire has become well ignited, and the draught is so regulated that little more than a slumbering fire is kept up, which at once economises fuel and prevents the possibility of the pipes being overheated. The degree to which the damper should be closed depends entirely upon the goodness of the draught; and a very few days'—even a few hours' experience will show the person in charge of the apparatus the point at which it is desirable to keep it. To most of the apparatuses recently erected by the patentee, a self-regulating damper has been attached, acting from the expansion and contraction of the pipe: when this becomes heated beyond any given point to which the damper has been previously regulated, the elongation of the pipe by the excess of heat acting upon the handle of the damper, partially closes it; the draught is thus checked and the fire lowered; the pipe consequently cools, and, in cooling, contracts; the contraction again opens the damper and the fire is revived. By this action of the self-regulating damper any degree of heat from the pipes may be maintained within a few degrees; if the damper be so fixed as to work the apparatus at 250°, it will be found that the heat of the pipes will range between 255° and 245°, whatever quantity of fuel may be thrown upon the fire; thus again the overheating of the pipes is effectually prevented, and an equal temperature at the same time obtained.

In the arrangement and fixing of any apparatus, regard ought always to be had (as has been already stated) to the due proportions of grate surface, heating surface, conducting and radiating surface, and draught; and where these have been duly observed, accident becomes impossible, even if the damper should be left wide open. It is not deemed necessary here to state the proportions the above surfaces should bear to each other, but their necessity is sufficiently obvious; an unlimited supply of heat arising from an excess of fire or heating surface and draught, with a limited means of carrying off that heat, must cause overheating somewhere, as is proved by the high temperature of the apparatuses at Birch Chapel, Mr. Barbour's Warehouse, the Strangeways Chapel, and the Natural History Museum; while, on the other hand, the due observance of these proportions renders an apparatus upon this system perfectly safe. Nor can it be considered that, in claiming attention to the foregoing points in constructing an apparatus, the patentee demands too much; it is the duty of every tradesman who undertakes to erect these apparatuses to understand them; and to such an one what has been said presents no difficulties; and surely common care and the usual degree of prudence required from every person attending upon fires may reasonably be asked for in the management of a hot water apparatus.

After this brief description of what a hot water apparatus erected upon Perkins' system ought to be, it is necessary now to examine whether the apparatus erected in Mr. Walker's premises, and experimented upon by Messrs. Davies and Ryder, is to be considered as an apparatus upon Perkins' system, and what degree of weight ought to be attached to experiments conducted as they were, and upon such an apparatus. It appears from the report of those gentlemen, that it consisted of 140 feet of tubing, of which 26 feet were coiled in the furnace. With these proportions of tubing no fault is found; but it seems from the diagram annexed to the report, that only 15 inches of expansion tube was attached to it (at least only that quantity was left unfilled with water), which, supposing it to be of three inches diameter, the largest size used, is six inches less than the apparatus required. This, in so small an apparatus, is a serious difference when worked at a very high temperature; still, however, under ordinary circumstances, the apparatus would have worked. The *damper* is not once mentioned in the report, nor does it appear that it was ever made the slightest use of during the experiments, so that the full force of the draught was admitted to the furnace at all times unchecked, even when it was loaded with fuel to repletion. This might suit the purpose of those who erected this apparatus with the express view of making it as dangerous as air, fire, and water, recklessly employed, could make it; but what tradesman would introduce one so constructed into his employer's premises? But more could yet be done to increase the dangerous tendency of this apparatus; and, accordingly, in the absence of Mr. Walker, a stop-cock was introduced, which, cutting off the greater part of the circulation, left only *forty feet of the tubing* out of the furnace, to carry off all the heat that could be communicated from *twenty-six feet within it*, with a fire out of all proportion to those surfaces, and a draught totally unchecked. With the apparatus in this state—a state in which no man in his senses ever before thought of working one, and which, it may be safely asserted, had never before occurred since the introduction of warming by hot water—preparations were made for an explosion. The process of "igniting," "destroying," "fusing," "inflaming," and "charring," various substances, went on most prosperously, and, at length, the desired explosion took place, the fire was thrown violently out of the furnace, and the ignited embers were scattered in profusion over every part of the place. Some gray calicos spread around the furnace were alone wanting to complete the scene, and put the finishing touch to this exquisite specimen of "Perkins' Hot-water Apparatus."

But can it be seriously intended that an apparatus thus erected, and thus worked, is to prove the *danger*, and caution the public against the use of Perkins' system of warming by means of hot water? Is the abuse of a thing to be used as an argument for discontinuing the use of it? To what invention will not such reasoning apply? Steam-engines, railways, all must vanish before it, since, if great skill and care are not employed in their construction, and much caution and prudence in their application, they become imminently dangerous.

Messrs. Craft and Stell's premises were burnt down; the fire was caused by the bursting of the furnace coil of the hot-water apparatus, which threw the ignited embers among combustible materials, and set them on fire. But was common precaution used in placing the furnace in such an apartment (the very walls of which were boards), and in surrounding it with grey goods? Would not a vault or a cellar have been a more appropriate place? and had the furnace been so situated, would the premises have been destroyed by the explosion which took place? This explosion was caused by a stoppage in the pipes; the water in them was frozen. It appears the warehouse was closed on Saturday evening, and not opened again before Monday morning; the frost being intense during the two intervening nights. A fire lighted in the furnace on Sunday morning was an obvious means of preventing such an occurrence; and it might have been supposed would have naturally suggested itself. Weather of such extreme severity is not very frequent in England, and the short time required for such a purpose (the necessity of it being evident) could scarcely be considered a desecration of the day. And even after the pipes were frozen up, common attention on the part of the fireman would have shown him the circumstance in a few minutes after the fire was lighted; the want of any circulation in the pipes being always indicated by their great heat near the furnace and their coldness in every other part. Had the fire then been raked out and the most exposed part of the pipes been thawed by the application of heat to them externally, the circulation might have been restored, and all would have been well. No precautions, however, of any kind appear to have been taken, and the endeavour to force a circulation in the state the pipes were then in, produced the disastrous event that ensued. It is not the object of the patentee to throw blame upon others, he only wishes to show that his apparatus may be used with perfect safety, if the same care and attention be bestowed upon it, as is required by every other mode of warming.

There are some palpable errors in the report of Messrs. Davies and Ryder in their remarks upon the inequality of the heat given out by the pipes in the Natural History Museum, and the manner in which they attempt to account for it. They observe, that the heat in those pipes had been repeatedly stated to become the greatest at places remote from the furnace, and that the fact was confimed by their own observations and subsequent experiments: and in another part of the Report they account for it by stating, that the minute bubbles of steam which rise rapidly to the upper part of the flow-pipe become there condensed into water again. From this acknowledged fact they deduce the inference that, "as condensed steam wherever it occurs produces about seven times as much heat as the same quantity of water at the same temperature, we have at once a reason for the heat of the pipe being generally greater at a distance from the furnace than contiguous to it." This is a manifest absurdity, for it is impossible that increase of heat can be produced by the condensation or cooling of steam. There cannot, therefore, be the slightest doubt that the statement of those gentlemen, that the heat is generally greater at points distant from the furnace than contiguous to it, is founded altogether in misconception and error. Another observation from which erroneous conclusions are drawn is, that the temperature of the pipes is influenced by the variation of their internal diameter, this is not the case; the amount of heat conducted off depends upon the surface exposed to the atmosphere, and not upon the internal diameter. Equal surfaces exposed to the atmosphere give off equal heat, whatever variation there may be in the velocity of the current of the water within the tubes.

The objection No. 1, relative to the possibility of an explosion from the inadequacy of the expansion tube, has been already met in the description of the apparatus in the former part of this paper; and overfilling the apparatus is impossible while the filling-pipe is made the only medium of supplying it, and the screw-plug of the expansion tube is at the time of filling taken off.

In objection No. 2, it is inferred that, because a pint of water may be converted into steam capable of exerting a powerful mechanical force, and present a pressure upon the tubes "sufficient to ensure their destruction," that such must inevitably be the case. Ten years' experience has, however, proved the contrary; any quantity of steam which can be formed in an apparatus properly put up, the tubes are perfectly able to resist.

Objection No. 3 supposes the presence of hydrogen gas in the apparatus to be a common occurrence, instead of a very rare one; and where it has occurred it has invariably arisen either from a faulty construction of the apparatus, or great neglect in its management. Admitting, however, that hydrogen gas has been formed within the pipes, no explosion can be produced by its expansion, as its expansive power is far less than that of water; neither can it explode within the pipes by ignition, as it requires an admixture of atmospheric air to render it explosive.

The remaining objection urged against the use of the apparatus is, the danger of explosion from stoppage in the pipes. This is a very unusual occurrence, and rarely happens except in seasons of very severe frost, when it may always be prevented by keeping a slumbering fire. The addition of three per cent. of salt to the water will also prevent it from freezing, even during such severe weather as was experienced last winter. The objection of stoppages by extraneous substances getting into the pipes, is scarcely worth notice; the last operation of the workmen in erecting a new apparatus is always to scour the pipes well through by means of a forcing pump, and then to close them up. How then can any substances get into pipes thus closed in every part, except by design?

It seems that previously to putting up the apparatus at Mr. Walker's, those at the Natural History Museum, and Messrs. Vernon and Company's, had been tried and found "unsatisfactory;" that is to say, they could not be sufficiently overheated. The patentee can show Messrs. Davies and Ryder some hundreds of apparatuses that would prove still more "*unsatisfactory*" to them than those just named. Since the foregoing remarks were written, Mr. Perkins has received a letter from Sir Robert Smirke, in which that gentleman says, "I am sorry to know that you think the partial use of my answers to the questions sent to me from Manchester (as printed in the Report there) has been in any degree prejudicial. If it has been so, I think you ought in the reply you are about to publish, to counteract that effect, especially as it was one not at all intended. They should, at least, have directed equal attention to my remark that complete security, under every contingency, might be obtained from the adoption of your safety-valves."

Comment upon this is unnecessary; it only strengthens the feeling which the perusal of Messrs. Davies and Ryder's Report has very generally produced, viz. that it is very unjust, and that the absurd experiments detailed in it were conducted with any view rather than that of candid investigation.

If those who possess the means of obtaining the information would make known the causes of all the fires that have come under their cognizance within the last eight or ten years, as far as they can be ascertained, the patentee is confident that such a statement would speak more in favour of his apparatus than the most laboured arguments. There are not wanting, however, many persons even in Manchester itself, who, placing more confidence in their own knowledge of the apparatus, founded on several years' experience, than in the Report, have unhesitatingly expressed their determination to continue the use of it as heretofore.

The safety-valves, alluded to by Sir Robert Smirke, have been but recently applied; and effectually provide for any casualty which can arise from a stoppage in the pipes.

In conclusion, the Patentee begs that the Directors of Assurance Companies, and the public generally, will not hastily form their opinion of Perkins' hot-water apparatus from the very erroneous reports which have been circulated respecting it, as it is his intention to request a committee of competent gentlemen connected with insurance offices to inspect an *apparatus properly constructed*, and which he *wishes* to have subjected to any test to which such committee may think proper to submit it.

LOCOMOTIVE ENGINES IN AMERICA.

We have received a copy of the Annual Report of the Canal Commissioners of Pennsylvania. Among the documents thereto appended, is the report of the superintendent of motive power on the Philadelphia and Columbia railroad, in which an engine built by Mr. Ross Winans, of this city, is spoken of in the most flattering terms, which applies not only to the particular engine, but to the class of engines built by Mr. Winans. We extract the following from the report:—"In addition to the different engines of the ordinary construction purchased by the undersigned, is one built by Ross Winans, of Baltimore, which, as well as others, was contracted for by a resolution of the Board, previous to the date of my last report. The general principle upon which this engine is constructed is similar to the one which, by the order of my predecessor, had been placed on the road near a year before my appointment. It is, however, entirely different in its proportions.

"This engine was constructed by special orders, as an experiment in the use of anthracite coal as a fuel to generate steam; and, on trial, has met all my anticipations. It is very large and heavy, with more than double the power of any other machine on the road. It burns anthracite coal exclusively, and from the additional space of fire-box, obtained by its increased size, has advantages in the use of that article, which is not, and which cannot be possessed by any other plan of engine. It is intended exclusively for the transportation of heavy trains of burthen cars. It will haul double the ordinary train, but owing to its great weight, must be run very slowly over the road."

We have understood that this engine rests its entire weight on *four propelling* wheels, each wheel supporting about the same weight as each one of the *two propelling* wheels of the largest class six wheel engines on the Philadelphia and Columbia road. The engine last built by Mr. Winans, and which we have before noticed, is still more powerful than the one spoken of in the report; but having overcome the difficulty that has heretofore been deemed insurmountable, of placing eight wheels under his engine, and connecting the motive power with all of them, so as to get the adhesion of the entire weight, without having a weight on any one wheel which is oppressive to the road. The engine now furnished weighs 19·33 tons, when in running condition, and is mounted on eight propelling wheels, which divide the weight equally among them, putting 2·42 on each wheel. The passenger engines of Norris' construction, in such extensive use, weigh about 10 tons when in running condition; but as they have only two propelling wheels, the greatest adhesion which they can render available, is that resulting from 6·70 tons resting on the driving wheels, which is but little more than one-third the adhesion obtained by Mr. Winans' eight wheel engine, while the weight on each driving wheel of the Norris is 3·35 tons, nearly a ton more than the weight on each wheel of the eight wheel engine. The power of every locomotive engine is limited by the greatest adhesion of its wheels on the rails; the adhesion is directly as the weight resting on the propelling wheels collectively. The greater the weight bearing on any one wheel the more destructive to the road. The greatest economy in transportation results from the use of the most powerful engines that can be employed consistent with the strength and character of the road on which they are to run; hence the advantage of increasing the number of propelling wheels.

An account was published a few days since, in a Philadelphia paper, of a gross load of 481½ tons being drawn over the Philadelphia and Reading Railroad, by an engine built by Messrs. Baldwin, Vail and Hufty, the weight of which is stated to be 11·92 tons, and the weight on the driving wheels 6·30 tons. As this is less than one-third the weight on the driving wheels of Mr. Winans' eight wheel engine, which has been shown to work to the full extent of its adhesion, it follows that it would be capable of taking over the Reading road three times the amount of the load above-named.—*Baltimore Clipper.*

The Railway Guard's Whistle.—Upon one of the London and Birmingham trains an apparatus is fitted up, consisting of rods attached to every carriage, and under the control of the guard, communicating with a whistle on the engine, called the "guard's whistle," quite distinct from the one sounded by the driver, and used only to give warning to him, to increase or decrease his speed, to stop, &c., according to signals previously a ranged and understood.—*Yorkshire Gazette*.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

February 9.—The PRESIDENT in the Chair.

Mr. S. Seaward explained the Table of Velocities of steam ships, which accompanied his paper. (See Journal for last month, page 168.)

The top line of figures represents the number of horses power, ranging from thirty to three hundred. The side line gives the tonnage of the steam ships, rising progressively from one hundred to twelve hundred tons. The intermediate spaces show the number of knots or nautical miles, which a ship of given tonnage, with a certain power, will travel through still water per hour.

The tonnage is calculated by the old rule (13 George III. cap. 74): "From the length substract $\frac{3}{5}$ths of the breadth, multiply that sum by the extreme breadth in the widest part, and again by $\frac{1}{2}$ the breadth, divide the product by 94, and the quotient will be the true tonnage."

The Table is constructed upon the principle, that each vessel of a good modern form will carry, at a proper draught, a weight equal to her measurement tonnage, and is presumed to be loaded equal to her tonnage, either by the weight of her engines, fuel or cargo, and it terminates at thirteen knots, at which speed the engines alone become the full load of the ship. The mode of constructing and of using the table was fully described, and examples were given.

It was shown, that an engine of thirty horses power would propel a ship of twelve hundred tons burthen, at the rate of 4 knots per hour, while three hundred horses power would only propel the same ship at the rate of $10\frac{2}{3}$ knots per hour. Hence, ten times the power would only produce about two and a half times the speed.

The principal points in the paper were more fully dwelt upon, and in answer to questions from some of the members, Mr. Seaward remarked, that no steamer in England had ever been propelled at more than fifteen geographical miles per hour, through still water.

In some of the Government mail packets, the engines and coals were the full cargo of the vessel. The table did not apply to vessels overladen with power, for as the weight increased in the ratio of the power, so the immersed sectional area was augmented, and the lines of the vessel which might be well calculated for speed when at a proper draught, became lines of retardation, and the engines did not work up to their proper speed, owing to the depth to which the paddle floats were immersed. For instance:—The wheels of the "British Queen" have been plunged between six and seven feet, instead of four feet, which was the calculated dip; the engines at the same time diminishing their speed so much as to reduce the effective power from five hundred horses to nearly three hundred horses.

The only advantageous way in which great power could be applied, would be by contriving to prevent the increase in the weight of the machinery and fuel, and those engineers, would be most successful who could so apply the materials of construction, as to ensure strength without the usual corresponding increase of weight.

Mr. George Mills, from his experience as a ship-builder, at Glasgow, was enabled to confirm all that Mr. Seaward had advanced. On the Clyde, the employment of an excess of power in steam vessels had been carried to the greatest extent, without producing corresponding advantages, either for speed, or in a commercial point of view. It would appear that the same error had to a certain degree been committed on the Thames, but less than on the Clyde; for on the latter river there were vessels with nearly double the power, in proportion to size, as compared with any vessel on the former river. He believed that on the Thames no vessels had so much as one horse power for each register ton, whereas on the Clyde, there were steamers of seventy to eighty tons register, having single engines, with cylinders of fifty-four inches diameter, which was more than one hundred horses power. It would appear that this application of extra power had only obtained a very moderate speed, while the great first outlay, with the commensurate current expenses, had reduced the commercial profit to the lowest point,—of this the proprietors alone could give any account; but as to the speed attained, he had seen three steamers of identical tonnage leave the Broomielaw at the same time, their engines being respectively of one hundred and ten, eighty, and sixty horses power; yet their speed was in the inverse ratio of their power: the vessel with the smallest engine arrived at Greenock first, the greater power second, and the greatest last. These remarks were only applicable to river boats. With regard to sea-going vessels, the system had not been carried to so serious an extent, yet with them the average proportion was about one horse power to two register tons, and some few reached as high as one horse to one and one-eighth of a ton.
